The reserved judgment delivered last week by Mr. Justice Bray in a Divisinal Court has an important bearing on the relationship of the medical profession to the National Insurance Act. It will be remembered that Dr. Alfred Salter, of Bermondsey, refused to sign a document supplementing his original duties by an undertaking to issue duplicate prescriptions. For that refusal he was dismissed by the London Insurance Committee. His action was sustained in the lower, and now has been endorsed by the Appeal Courts. In effect, the Insurance Committee has received a sharp reminder that it can exercise no arbitrary powers over the rights of medical men on the panel. The just administration of a great and complicated Act is absolutely essential for the development of its admitted potentialities for good. The Act is with us, and while there is no justification for the continuance of unreasonable and vexatious opposition, it is nevertheless desirable in the interests of all concerned to watch its administration with unrelaxing vigilance. Dr. Salter deserves the congratulations of the profession for his determined action. We should be glad to consider a formal presentation of thanks if an adequate number of our readers affirm their active approval of some such step.

In our issue of last week it was pointed out that the name of a member of the General Medical Council appears on the list of "contributors" to the "Family Encyclopaedia of Medicine." We have since received from the gentleman in question a positive disclaimer of authorisation of the use of his name in that connection. That being the case, it may be presumed that Sir Clifford Allbutt has the remedy in his own hands. No one acquainted with his distinguished character and work would for a moment imagine he had voluntarily sought publicity of the peculiar nature extended to those medical men whose names, titles and professional appointments were published at full length in the first three fortnightly numbers of the work: in whole columns of lurid newspaper advertisements, and, horribile dictu, upon sandwich-boards paraded through the streets of London. From the first appearance of this portentous popular work it has been insisted in these columns that the medical men concerned were quite within their rights even if they actually assented to the use of their names in connection with a pseudo-professional publication. As a matter of fact, it was announced not long after the first outcry against its methods of publicity that the gentlemen concerned had met and decided not to take legal action. Later it was stated that the publication of the names, titles and appointments would cease with the issue of the third number. It was also generally intimated that the "contributors" were not paid for their services, which mainly consisted of revision of proofs.

What do we find in the ninth part, the last which has reached the public? The issuing of fortnightly numbers has now extended over some four months, so that ample time has elapsed for the "contributors" to consider their position and to take stringent steps to put themselves right with the medical profession, or, at any rate, with that portion of it which still regards their conduct with respect the somewhat adverse criticisms that have hitherto regulated the relations of medical men to the public as regards purely professional topics. The ninth issue contains an article on eczema, and the original prospectus and the earlier numbers infirm us Sir Malcolm Morris is responsible for that part of the work dealing with diseases of the skin. A perusal of the article shows that the name of Sir Malcolm Morris occurs twice, first, apparently as the authority for a wholly unhistorical classification of eczema, and, secondly, in reference to his well-known book on "Diseases of the Skin." It may be assumed that Sir Malcolm Morris could not have written the article, neither could he be any possibility have passed proofs which referred the lay
Another Skin Book. The editor of the "Encyclopaedia," in permitting these references, displays little or no intention of amending his ways. It was pointed out some months ago in these columns that in the first three numbers references were made to certain medical text-books, amongst which was one by Dr. J. H. Sequeira. That gentleman's book needs no commendation in medical circles, where it is recognised as an authority—but why advertise it to the public? The editor of the "Encyclopaedia," for some reason or other best known to himself, seems to think that the lay Britisher needs special illumination upon that complicated branch of study commonly spoken of as dermatology. Dr. Riddle, moreover, exercising his undoubted right as an editor has seen fit to give special prominence to the works of two writers, Dr. J. H. Sequeira and Sir Malcolm Morris. The writers of other books upon diseases of the skin probably will not in the long run regret that their reputation will depend on agencies other than the commercial activities of Messrs. Harmsworth. In future it will be difficult for anyone to blame any medical man who may seek publicity in lay publications for his professional qualifications and for medical books of his own production. The difference, however, between his case and that of the "contributors," is that the latter have not to pay for the notice of their names, whereas non-contributors to the "Encyclopaedia" would find newspaper notices obtainable only at high advertisement rates.

The Deadly Nexus. If the "contributors" have been basely tricked and their names used unwaribalently by the proprietors of the "Encyclopaedia," why do they not take immediate steps to set themselves right with their professional brethren, who so far have escaped the deluge? Nor surely is it the unworthy by-up-to-date publishing enterprise? A legal remedy has apparently not commended itself to their collective judgment. Short of that, it would at least be possible for them to bring such pressure upon the editor, Dr. Riddle, as to prevent the further insertion of names and pointed allusion to technical medical books in current numbers. Month by month interest and astonishment of the dental world, and by this time contributers should at least have secured a clear understanding as to the methods to be adopted in the completion of the "Encyclopaedia." The medical profession is entitled to something more than a general transference of the blame to editorial shoulders. Nor can anything be gained by turning the weapons of sarcasm and obloquy upon the Medical Press and Circular, which has merely acted on its traditional policy in defending the honour of the profession. Rather should the "contributors" thank us for the opportunity afforded by our comments to explain the why and wherefore of their presence in that galaxy. The medical profession is good-natured and charitable in a matter of this kind, but a hushing up policy is hardly likely to evoke its spontaneous and sympathetic forgiveness.

Artificial Teeth for the Poor. It is a curious fact that no provision has been made in recent health legislation for supplying artificial teeth for the indigent poor. A great deal of preventable suffering is brought about by faulty dentition, as every medical man knows, in fact, oral sepsis is responsible for many grave systemic disorders. In the absence of national dental insurance benefit the burden of attending to the dental needs of the poor must needs be borne by private philanthropy, though the dental hospitals do what they can to relieve the poor in this direction. An inquiry as to the number of sedentulous persons among the poor, especially in the East End of London, would, no doubt furnish some interesting data; at the same time it could hardly fail to call public attention to one of the most crying needs of the day—namely, the inclusion of dental benefit in that granted under the National Insurance. A handsome gift was announced the other day from Mr. Edwin Tate, of Park Lane, of £5,000 to St. Bartholomew's Hospital, the income of which is to be used "to assist nedulous persons to obtain artificial teeth." Under the terms of this fund it is stated that such persons may be assisted to the extent of one-half of the estimated cost of the teeth. Nothing will be paid until the dental surgeon recommending the case has certified that the teeth supplied are satisfactory. The systematic dental inspection of school children is too much to benefit the dentition of the rising generation, but something still needs to be done in the direction of inspecting the mouths of older people in workhouses and elsewhere.

LEADING ARTICLES.

HOW TO COMPENSATE A DIMINISHING BIRTH-RATE.

A diminishing birth-rate has of late years become a matter of serious socio-political significance. Its incidence appears to be an outcome of the increasing complexity of life and it has affected, more or less profoundly, the civilised nations of the world. In the case of France the falling off in population has been so great as to arouse the apprehension of responsible politicians and students of social science. So far it can hardly be said that any satisfying conclusions have been arrived at with regard to the contributory causes of the decline, or to the best means of combating the same in the interests of the community. At the same time certain points have been established. For instance, the fact that both the marriage and the birth-rate rise in proportion to the material prosperity of a nation may be accepted as more or less axiomatic; similarly, the unequal distribution of wealth is closely concerned in the diminution, a statement that is borne out by the fact that fecundity is, broadly speaking, in inverse ratio to parental wealth. Poverty-stricken Whitechapel is peopled by large families, while wealthy Mayfair counts its children by twos and threes. But although the economic factor admittedly plays an important part in the matter, it by no means accounts for the whole of the modern civilised movement in favour of small families. The average age of marriage has become later and later, a fact that is probably due in the main to economic causes. The increasing disinclination of women to bear children is largely due to their recognition of the shortened life and impaired health consequent on frequent childbearing. Against a conclusion of that kind the
morality is hardly likely to declaim with much effect. For that matter it does not appear that any
one has so far provided an efficient remedy to stem the steady decline of the birth-rate. Last
week Lord Haldane threw some philosophic light upon the problem. He observed that the diminu-
tion of the birth-rate might be not altogether an evil. It might mean that people were more careful
in contracting marriages, and that there was a general desire, far spread, on the part of the people
to bring up their children in a better way than they have in the past. He then dealt with the crucial point
of compensation for a lessened number of births by a decreased infantile and juvenile mortality.
Therein lies, if we mistake not, the key to a states-
manlike handling of the diminishing birth-rate.
Lord Haldane dwelt not only upon the children who had come into the world and died during the first
twelve months, but also upon those who had never come into the world at all, although under proper
conditions they would have added to the normal increase of population. The statistics he stigma-
tised as “frightful.” The death-rate during the first twelve months was 128 per 1,000; while the rate of
full grown and healthy children still-born was 150 per 1,000. Recent legislation has endeavoured
to ameliorate the condition of maternity amongst the poorer classes of society, both as regards the
conditions of maternal labour and of medical care and nutrition during and after the confinement.
As to the children, much has been done by extending relief to working classes during unemployment,
by the provision of a wide system of medical aid and by the feeding and medical care of school children.
In these various ways the adverse effects of a lessened birth-rate will in all probability be more or
less counterpoised. The causes of the diminution are complex and obscure, and for their detection
as well as their remedy we must turn to the better organisation of society as regards the dis-
tribution of wealth and the other internal economic relationships that lie at the root of all progress in
the public health.

CURRENT TOPICS.

Maternity Benefit and Midwifery Teaching.

A SPECIAL committee was appointed at the begin-
ing of the year by the Glasgow Obstetrical and
Gynecological Society to inquire into the effects
of the maternity benefit upon the teaching and
practice of midwifery in Glasgow during the first
year of the National Insurance Act. The com-
mitee’s data were obtained (a) from medical institu-
tions and public bodies; (b) from the replies of
general practitioners to a series of questions
addressed to 450 medical men. Of the 222 who
made returns, only 166 gave replies suitable for the
purpose of the inquiry. In their report recently
issued the committee states that to the general ques-
tion whether the maternity benefit had favoured the
comfort and safety of the mother and child, 57
practitioners replied in the affirmative, 36 in the
negative, 16 had observed no change, 3 were of
opinion that the Act had been prejudicial in this
direction, 24 that the effect was doubtful or partly
beneficial and partly prejudicial, while 30 could
express no opinion. In such a diverse opinion
in the general result of the replies to this question
in itself would appear to indicate that the maternity
benefit has not promoted in Glasgow the comfort
and security of mothers and infants to the extent
that might have been hoped for. Giving the effect
of the replies to the special questions, the com-
mitee states that the medical profession as a whole
has not obtained—nor does it desire—an increased
amount of maternity work in consequence of the
Insurance Act. On the other hand, as there has
been a marked decrease in the number of cases at
the Maternity Hospital and the Poor-law hospitals,
it is to be inferred that more work is being done by
midwives. It does not appear that the trained
nurse is more frequently employed—and in any case
the untrained midwife continues in favour. The
explanation suggested by the committee is that
now that there is money available, housekeeping
services, which formerly were given free by friends
or neighbours, have to be paid for. Consequently
the “handy woman” who will care for the house
as well as the patient is preferred. The decrease—
amounting to 30 per cent.—in the outdoor practice
of the Maternity Hospital is stated to be a serious
hindrance to midwifery teaching.

The Death-Rate on the Rand.

A severe indictment of the conditions of native
labour in the gold mines of the Rand is disclosed
in the report made by Dr. W. C. Gorgas, Surgeon-
General to the U.S. Army and chief sanitary officer
of the Panama Canal Commission, who was called
in by the Transvaal Chamber of Mines. In the
report which appears in the Journal of the American
Medical Association, Dr. Gorgas brings out the
startling fact that the death-rate among natives
employed in the Rand mines in 1903 was over 71^2
per 1,000. This had fallen in 1912 to just over 26
per 1,000, which, says, Dr. Gorgas, is “still very
much too high, as we are considering men in the
prime of life.” The Panama Canal zone is
notoriously unhealthy, but the death-rate among
the negro labourers on the Canal, in 1913 only 10
per 1,000, one third less than half the Rand record.
The principal causes of this slaughter are pneumonia
and tuberculosis, and Dr. Gorgas found that in the
living quarters each native was only allowed 14 feet
of floor space, against a reasonable minimum of 50
square feet. He says the remedy for the existing
high death-rates is to allow the natives to bring
their families with them and allow each family
to be housed in its individual hut, rather than have
large numbers of native labourers crowded together
in compounds, as is the case at present. All
experiments failed on the Panama Canal zone until
this method was adopted, and he strongly advises
the abolition of the Rand compounds. It is to be
hoped that the South African Government will see
that this reform is carried out.

Children’s Country Holidays.

The attention of the Local Government Board has
been called to complaints that are occasionally
made as the result of town children being sent away
to lodge in country districts by various philan-
thropic organisations or agencies. Sometimes
children are said to bring disease into a village,
or the want of sanitation and overcrowding some-
times prevalent in the village are prejudicial to the
health of the inhabitants as well as to the children
themselves. A circular has accordingly been issued
by the Board to public health authorities through-
---

July 1, 1914.  CURRENT TOPICS.  THE MEDICAL PRESS. 3
out the country suggesting certain ways in which precautionary measures can be taken. It is not proposed for a moment to place any check on the country holiday movement, but it appears that the uncertainty in the present practice of the different agencies renders it advisable that effective preventive action should begin with them. It is suggested that the medical officer of health of the country district in which the children are sent should be communicated with in all cases, preferably by the central office of the agency, rather than by any individual voluntary workers. Careful inquiries should always be made as to infectious disease before the children are sent, so as to ensure, if possible, that they are not in an infected condition, nor in the incubation stage of any acute infectious malady. Greater care should also be taken to secure cleanliness of body and clothing before the children are sent away, and the assistance of cleansing stations might be sought, where necessary, for this purpose. Finally, the necessity of calling in medical advice should a child fall ill when away is rightly urged, and should infectious disease occur, the medical officer of health of the district should be at once informed. If local authorities and the holiday agencies would exercise greater supervision the complaints referred to should never arise.

Medical Certification in Ireland.

The settlement of the certification question in Ireland has been again postponed. The present arrangements are to continue until October 31st next. That is to say, that in some eight or nine administrative areas the existing panels are to continue, while in the rest of the country insured persons will still rely on the good nature of the profession to provide evidence of sickness, such evidence being subject to review by "medical advisers," district nurses, railway porters, and other such experts. The position is highly unsatisfactory from every point of view, but it is nevertheless better than it might be. It is, at least, not irrevocable. There is no doubt that the establishment of a permanent system of the worst possible character—a system of paid medical certifiers—was imminent. It is a sign of grace in the authorities that they have, despite the extreme political pressure brought to bear on them, remained, at any rate for the time, free from committing such a crime and blunder. The arguments put forward on behalf of the insured at the recent meeting in the Dublin Mansion House, and pressed on Mr. Masterman by the deputation which visited London a few days later, are irrefutable. All that is necessary to establish a system which will be satisfactory to the profession, and will secure justice for the insured, is absolute firmness on the part of the profession, backed by a determination on the part of the insured to secure their rights.

Antidotes Included.

The Americans are a humorous folk, but they do not always know it. They have the laughable habit of taking things seriously. They are the only serious nation. It has been solemnly suggested that tablets of perchloride of mercury should contain 13 grains of tartar emetic, so that "the drug should produce vomiting before the bichloride of mercury is absorbed and before it exerts its irritant action." It is fairly typical of transatlantic caution to consider the average man either a complete fool or an incorrigible suicidal maniac. It is what they call sense and science. One firm across the ocean sells tablets of perchloride shaped like coffins and impressed with a skull and crossbones. That would not deter the determined suicide, and it is questionable if it would save the fool. If enough people are going to be sufficiently careless to swallow contraceptive tablets in mistake for "headache powders," to make such complicated amateur legislation worth while, we can do little but be thankful we are not as other men are. For all that, the idea of incorporating an antidote with every nostrum thing on the market is capable of unlimited expansion. It would be sufficient to dressings of potassium bichloride with every bottle of whiskey is a good idea, and would probably do well till the price of the drug became prohibitive. There is no end to the possible combinations. Every irresistible force would be wrapped up with an immovable object. Motor cars and attendant policemen would be coupled; fair ladies and 606; and every man who bought a safety razor might be presented, free, with a trained ambulance man and a triangular bandage.

Of Subcutaneous Interest.

In these times of organotherapy and complicated synthetic medication the means whereby these new powers are given into our control is neglected. We can pour things into the mouth, we can introduce them by the gut—we cannot do it at the point. We cannot rely on the subject being well, it is a most ambiguous step. By the time the patient is referred to the bar of science, and the barman is the cautionary, he is a doubtful subject. The performance of the barman can never be adequately ascertained. There are no authorities to look at, and we are left to infer what has passed. Hypodermic syringes are used, we suspect, in less than 20 per cent of cases which in a majority of instances have been used. The syringes are used by farmers in the fields, by hospital servants, and everyone. It is a very loose and uncertain method. A small sprig of mistletoe is no substitute for a well-trained and skilled medical attendant.

The Five Neglected Years.

The proposal to establish a clinic for babies and children under school age, recently adopted at a conference held at Manchester under the auspices of the Manchester and Salford Sanitary Association, will be welcomed by all those who have the physical welfare of infants at heart. The ordinary school clinics have proved of great value in dealing with physical defects and ailments among school children, but, as Dr. Benjamin Moore pointed out, one-fifth of all the deaths in the community occur in
children under five years of age. Half the doctoring carried out by medical men is practised among infants and young children. The "five neglected years" during which disease is often left to run riot among young lives are those between a child's birth and the school age. Up to the present health legislators have ignored this important period of human existence, though the need for care and hygiene during these early years are more pressing, perhaps, than at any other time. From the economic point of view, as the Lord Mayor of Manchester remarked, properly conducted baby clinics would eventually prove to be a great saving to the nation, and instead of increasing the rates would reduce them. A good deal of preventable blindness, for instance, might well come within the scope of such clinics. It would be a good thing if the existing schools for mothers could be developed into baby clinics, and, in this manner some degree of overlapping of charitable and municipal enterprises might be saved.

Emetine as a Therapeutic Agent.

Of the three alkaloids found in ipecacuanha root, emetine, cephaeline and psychotrine, the former is the one to which the drug owes its efficacy in cases of amebic dysentery. Owing to the vomiting occasioned by its administration the remedy fell more or less into disuse, until it was revived by Sir Patrick Manson in 1900. Eleven years later, Capt. E. B. Vedder, of the Medical Corps, United States Army, undertook some experiments on the bacteriologic properties of ipecacuanha in dysentery, and Sir Leonard Rogers, of Calcutta, followed these up later from the clinical aspect. It was found that one-sixth of a grain of emetine hydrochloride given hyperdermically caused the disappearance of blood from dysenteric stools, no vomiting or depression being observed. Thus ipecacuanha has been robbed of all its former terrors and discomforts, and it may be said that emetine constitutes a specific treatment for hepatitis and dysentery of amebic origin. In an admirable résumé of the subject contributed to the Therapeutic and Pharmacological Section of the Royal Society of Medicine, Dr. George C. Low states that keratin-coated tabloids may be given, with better results than are produced by the injections. More recently it has been found that emetine is useful in the treatment of hemoptysis and intestinal hemorrhages. Even in hemoptysis the remedy has been employed with success, and it may be noted that no change either in the blood pressure, coagulation of the blood, or in the blood-count was observed after an injection. Hemorrhage in typhoid and in chronic nephritis has also yielded in a similar manner to the treatment. It would seem, therefore, that we have in emetine a useful means of arresting hemorrhage, being comparable or even superior to supra-renal extract in this respect.

PERSONAL.

H.M. THE KING, during his tour in the Midlands last week, opened the King Edward Memorial Wing of the Mansfield Hospital and also laid the foundation-stones of the Municipal Tuberculosis Sanatorium and Hospital at Hull. In both cases the ceremony was performed by pressing an electric button.

COL. SIR WILLIAM B. LEISHMAN, R.A.M.C., and Dr. Louis C. Purser, of Dublin, were among the recipients of the honorary degree of L.L.D. of the University of Glasgow last week in connection with the Commemoration Day celebrations.

DR. GUSTAV MONOD, M.D.Paris, M.R.C.P.Lond., has been appointed Physician to the Vichy Thermal Hospital.

DR. J. GOODWIN TOMKINSON has been appointed Lecturer in Diseases of the Skin at Anderson’s Medical College, Glasgow.

The Earnshaw Cooper Gold Medal in Dietetics has been awarded to Dr. W. Bamford Winston, M.B., M.R.C.S., L.R.C.P.

DR. FRANCIS E. FREMANTLE, County Medical Officer for Hertford, has been chosen as one of the Unionist candidates for Stockport.

DR. HENRY DEVINE, M.D., B.S.Lond., M.D.Bristol, M.R.C.P., has been appointed Medical Superintendent of the Portsmouth Borough Asylum.

MR. P. T. CRUMBIE M.B., F.R.C.S.Eng., has been elected to the new lectureship of Applied Anatomy in the Queen’s University of Belfast.

We are glad to learn that Dr. Edwin Rayner, the Treasurer of the British Medical Association, is making a good recovery after his recent operation for appendicitis.

PROFESSOR ARTHUR THOMSON, M.A., M.B., F.R.C.S., will preside at the official dinner of the Oxford Ophthalmological Congress at Keble Hall on Thursday, July 9th.

MR. JAMES M. GRAHAM, M.B., Ch.B., has been appointed University Lecturer on Surgical Pathology in the Department of Surgery in the University of Edinburgh.

DR. CHARLES JOHN SHAW has been appointed Physician Superintendent to the Monrose Royal Asylum in succession to Dr. J. G. Havelock, who is retiring from the post.

DR. W. E. CARNegie DICKSON, M.D., F.R.C.P.Ed., has been appointed Director of the Pathological Department and Research Laboratory of the Royal Hospital for Diseases of the Chest, City Road.

On the occasion of the tercentenary of the founding of Groningen University the honorary degree of Doctor of Medicine has been conferred upon Sir Edward Schaefer, Edinburgh, and Professor J. N. Langley, Cambridge.

DR. T. N. PARRY, J.P., of Ferndale, was the recipient the other day of a handsomely illuminated address from the members of the Ferndale Conservative Club in recognition of his services on behalf of the club and to the cause generally.

The Nuneaton town council have voted their Medical Officer of Health (Dr. V. Gray Maitland) an honararium of £25 for extra work carried out by him in connection with the treatment of tuberculosis at the Tuttle Hill sanatorium.

The following promotions and appointments to the Order of the Hospital of St. John of Jerusalem in England have been sanctioned by H.M. the King:—To be Knights of Grace, Colonel D. J. Macintosh, M.V.O., A.M.S. (T.F.); Dr. J. MacIntyre, and Surgeon-General W. W. Kenny, K.H.S., A.M.S.

SIR FRANCIS HENRY LAKING, first Bart., G.C.V.O., K.C.B., M.D., LL.D., of St. Clevelands Row, Westminster, S.W., late Physician-in-Ordinary to King Edward VII., to King George V., and to Queen Alexandra, left estate of the gross value of £24,496, of which the net personality has been sworn at £20,033.
CLINICAL LECTURE
ON
PERNICIOUS ANÆMIA WITH SPECIAL REFERENCE TO ITS
ATYPICAL SYMPTOMS AND COMPLICATIONS. (a)

By ALEXANDER GOODALL, M.D., F.R.C.P.Ed
Assistant Physician to the
Royal Infirmary, Edinburgh.

Last session we studied a typical case of pernicious anaemia. You may remember that the patient was a man, aged 35, who complained of muscular weakness. He showed a remarkable degree of pallor combined with a peculiar lemon-yellow colour of the skin. His temperature ranged from 90 to 101. He was breathless on slight exertion, and his pulse was rapid and feeble. Altogether his symptoms were so striking that a senior student could hardly make a wrong diagnosis. Then we examined his blood and found that when a drop exuded it looked pale and watery, the red corpuscles numbered only 900,000 per c.mm., the haemoglobin percentage was 25. We noticed the importance of the relationship of these figures, that is, the colour value of each corpuscle or the colour index. It is obtained by dividing the percentage of haemoglobin by the percentage of corpuscles. The latter is obtained by an easy exercise in simple proportion or even more simply by multiplying the first two figures of the blood count by 2 (only the first figure when the count is less than one million). In this case 25/18 = 1.38. Now a colour index over unity is practically distinctive of pernicious anaemia. Then we found that the leucocytes were reduced to 3,000 per c.mm., the cells chiefly diminished being the polymorphs. In stained films we noticed the greatly increased size of the red corpuscles, their inequality in size (anisocytosis), some deformity (poikilocytosis), and an undue affinity for the basic stain (polychromasia). Some of the corpuscles showed this polychromasia in a diffuse form, but there were a few in which the polychromasia showed in the form of dots—basophilic stippling or punctate basophilia. Then we noticed the presence of nucleated red cells. The majority of these were large cells with a large nucleus showing a very distinct chromatin network. These were megaloblasts. Then we noted a few normoblasts, cells about the same size as the red corpuscles, but with a small deeply staining or pyknotic nucleus. I laid stress on three points, the high colour index, the increased average size, and the presence of megaloblasts as definitely establishing a diagnosis which, however, was never in doubt.

What I wish to emphasise to-day is that not half of the cases of pernicious anaemia show the classical clinical symptoms, and that the blood picture, while usually distinctive enough, does not always present such a striking picture as that of the last case. We are fortunate in having illustrations of these features, for there are at present three cases in the ward, none of which were sent in as cases of pernicious anaemia, and in none of which is anaemia the most striking symptom, although in two of them its degree is extreme. I wish to show you five cases altogether. They are all seriously ill, so the simplest plan for all concerned will be for us to go to the ward and see them there.

CASE SIMULATING GASTRIC CARCINOMA AND DEVELOPING ACUTE MANIA.

This is a married woman, aged 47, who lives in a historic but not very salubrious part of our city, the Canongate. She says that she was taken ill only five days before admission. Her complaint was vomiting and diarrhoea. She was seen by a doctor, who, not unreasonably thought that she might be suffering from gastric carcinoma, and sent her to hospital. Her family history is satisfactory. Her social conditions are not what a residence in the Canongate would have implied in the time of the Stuarts. She has apparently never been a bigoted teetotaller, but asserts that for the last eight years her alcoholic refreshment has been limited to "about" one glass of whisky a week. As regards previous illnesses, her left leg was amputated evidently on account of some septic trouble when she was seven years of age. She had bleeding piles for a long time, but was cured by operation many years ago. She has had several attacks of bronchitis. Although she tells us that she has only been ill for five days before admission she had noticed increasing weakness for some months. The vomiting began suddenly. She says that it was coloured like coffee. She then began to suffer from diarrhoea, and says that she fainted. She also complains of some abdominal pain.

Her history is thus every whit as suggestive of a gastric neoplasm as of her real illness, and the diagnosis rests on the results of our examination.

She looks fairly well nourished, the skin is lemon-yellow and the mucous membranes show a marked pallor.

The teeth are decayed and dirty. The tongue is slightly furred but shows none of the glazed, atrophic areas which are sometimes seen. Free HCl is absent in the vomited material.

There is a little epigastric tenderness and some splashing can be elicited after food. The pulse rate is 96. Its tension is low. A soft systolic murmur can be heard at the aortic and pulmonary areas, but there is no cardiac enlargement and no evidence of valvular disease. The chest is rather emphysematous.

Here then is a case where the history is misleading, and the physical examination cannot be said to clear up the matter. Her colour, her weakness, the vomiting, the absent HCl, and the systolic murmurs are found in cases of gastric carcinoma as well as in pernicious anaemia. We know that in many cases of gastric neoplasm there is no palpable tumour. We depend, therefore, on the blood examination for the diagnosis. Her
red corpuscles number 1,500,000; the haemoglobin percentage is 40, giving a colour index of 40-1.3. Her leucocytes number only 2,000, 30 blood plates, too, are diminished, and the stained films are typical of pernicious anaemia. Our difficulty disappears as soon as we know about the blood. But this case illustrates another feature of pernicious anaemia. On several occasions she seemed to labour under imaginary grievances, but these did not seem of much importance. But a few nights ago, when the House Physician was making his visit, this good lady suddenly got up and attacked him with her teeth. The hand of an absent leg and the intervention of the nurse averted a tragedy, and the patient's excitement soon settled down. Her mental condition is, however, not by any means normal. For instance, she tells us that her husband stood all last night outside her window without being allowed to come in, a remarkable feat of devotion, as we must be some 40 feet from the ground up here. With a little encouragement she will readily discuss a number of other defusions.

**CASE OF CARDIAC DISEASE SIMULATING PERNICIOUS ANAEMIA.**

I wish you just to look at this case. You notice a marked pallor and a very sallow look, which is a little suggestive of pernicious anaemia. She, too, came in suffering from an attack of gastric derangement, and there was marked breathlessness. She is anaemic. Her red cell count is just over three millions, and curiously enough in the first field I looked at in the stained film I saw a normoblast. Her colour index, however, is low and the films are in no way suggestive of pernicious anaemia, while if you examine her heart you will find ample evidence of a chronic valvular disease to account for all her symptoms.

**CASE OF PERNICIOUS ANAEMIA WITH SEVERE RESPIRATORY COMPLICATIONS AND NEURITIS.**

Our next case is a married woman, aged 71. She came in complaining of pain and tingling in her fingers and toes, and the diagnosis made outside was neuritis. This is quite correct, but it is not the whole truth. She has a comfortable home. She has brought up a large family, and has had no previous illnesses of importance.

Her present illness began about two years ago, when she suddenly felt numbness in the toes of the left foot. A similar sensation alternating with tingling began in the other foot and in both hands, and has persisted till the present time. The hands and feet then became painful. A variety of remedies were tried, but failed to give relief, and she was recommended to come to hospital.

We find the patient to be only fairly well nourished. She is bright and intelligent. She had all her teeth removed over six years ago. The tongue is clean. There are no signs of dyspepsia. The bowels tend to be confined, but have been kept regular by the use of cascara. There were no special symptoms referable to the circulatory system, but as you now see she is suffering from a considerable amount of dyspnoea, so that she has to be propped up in bed. This is accounted for by the fact that a few days ago she began to suffer from an attack of subacute bronchitis, with a good deal of spasm. This was accompanied by an attack of pleurisy. The left side, which is fortunately subsiding without any defusion. She is now free from pain and is not afraid to breathe freely, consequently you will be able to hear friction very easily as well as ronchi due to the bronchitis. We are particularly pleased that improvement is taking place, because the respiratory complications of pernicious anaemia are very formidable. Many cases die from attacks of broncho-pneumonia, and pleuritic attacks often go on to defusion and empyema. A closer investigation of the nervous system shows little. By way of one has already indicated. The symptoms are mainly subjective, but there is impaired sensibility to touch in both feet and hands. Now, here is a case which was sent in as a neuritis, and which would readily have been diagnosed as a neuritis by anyone. This type of neuritis—numbness and tingling with little objective evidence is, however, fairly common in pernicious anaemia.

Anyone seeing the case for the first time now might readily be excused for ascribing the symptoms to the worst condition and overlooking the blood condition altogether.

The anaemia is certainly not very severe. The red corpuscles number 3,000,000, the haemoglobin percentage is 68, giving a colour index of 1.1. Films show a definite macrocytosis with a considerable diversity in size. We have never seen nucleated red cells of any kind. The leucocytes number only 4,000 in spite of the inflammatory complications in the chest. As regards the blood you note that I did not mention poikiloctyosis. As a matter of fact it is hardly noticeable, and this is in keeping with what we find in the chronic and less acute cases. Poikiloctyosis may be extreme in the acute cases, but in the chronic cases it is seldom seen. I know you will find a contrary statement in many text-books, but I think that is an error. There is anisocytosis which gives an irregular appearance to the films, and this is put down to poikiloctyosis. In fact, I have often been led to a diagnosis of pernicious anaemia by the absence of poikiloctyosis in relation to the haemoglobin percentage. If one finds a haemoglobin percentage of, say, 60, and finds but slight poikiloctyosis one has reached a point strongly in favour of a diagnosis of pernicious anaemia. In any other anaemia with a haemoglobin percentage of only 40 poikiloctyosis would be extreme. Then as to the absence of nucleated red cells, one can seldom reckon on finding them when the count is above half a million, and even in much more severe cases in old people they are by no means numerous. But here we have two important diagnostics, high colour index and macrocytosis.

**CASE OF BRIGHT'S DISEASE WITH ANAEMIA.**

Now I want you just to look at the patient in the next bed. Pallor is extreme. Indeed, of all the cases in the ward I think most of us would say that this one shows the most intense pallor. Yet she is by no means the most anaemic, and her anaemia is not of the most serious type. She has 3,400,000 red corpuscles and 50 per cent. of haemoglobin. This gives a colour index of only 0.75. The case is therefore one of secondary anaemia, and is due to subacute nephritis. I show you this case because many mistakes are made between these two conditions, and in both directions. One has frequently seen cases with albuminuria labelled nephritis when the underlying condition was really pernicious anaemia. A great many cases of pernicious anaemia die of uraemia.
CASE OF PERNICIOUS ANÆMIA SIMULATING ADDISON’S DISEASE.

I wish now to refer to a case which I have seen outside in consultation. I am sorry he is not here to show you. Patient was a man, aged 55, who complained of great muscular weakness, particularly of being easily tired, and of some breathlessness. On examining him I found little except some indication of a slightly shrunk lung at one apex. The most striking feature of the case was a remarkable pigmentation, chiefly affecting the abdomen and to a less extent the thorax. I was told that the weakness had lasted for some years, and that it had been ascribed to pernicious anæmia. The blood showed the following:—Red corpuscles, 3,650,000; hemoglobin, 60 per cent.; colour index, 0.83; leucocytes, 7,200. Films showed very little. Here was a puzzle. The pigmentation suggested Addison’s disease, and there seemed to be an old tuberculosis focus in the lung which was in keeping with the possibility of tuberculosis affecting the suprarenal capsules. The blood was not distinctive of pernicious anæmia. On the other hand, the pigmentation had not the typical distribution of Addison’s disease, and the opinion of the consultant who had seen the patient in England was not to be taken lightly. The matter could not be decided at the time, but I saw the patient five months later. The count had then fallen to 500,000, the hemoglobin to 30 per cent., and the colour index had risen to 1.5. In stained films the picture of pernicious anæmia was distinct. Pigmentation is moderately common in pernicious anæmia, especially when patients have been taking arsenic, but it may occur before any arsenic has been prescribed.

CASE OF PERNICIOUS ANÆMIA SIMULATING ACUTE YELLOW ATROPHY OF THE LIVER.

This woman was aged 33. Her history is given in a letter from her doctor, who tells us that the patient gave birth to twins three weeks ago. During the pregnancy she complained of pain in the region of the liver. The labour was not severe, and there was no unusual loss of blood. Ever since, however, she has looked exceedingly anaemic. Once or twice she has had haematemeses. Latterly there has been incontinence of urine and faeces. The pulse has been between 120 and 130, and she has complained of pain in the right costal region. She has been rapidly losing weight.

You notice the intense pallor of her lips. There is a yellow colour of the skin and a slight icteric tinge in her conjunctive. The patient looks ill-nourished and anxious. The temperature is 96°. The tongue is very dry and coated with a sticky brown fur. The mouth is so dry that she can only speak with difficulty. There is some abdominal distension, so that the liver dullness is diminished. There are hemic murmurs, and the pulse is rapid and feeble. Respirations are rapid, short and laboured. The alæ nasi move with respiration, but there are no physical signs of disease in the chest. The patient is dull and apathetic, and the pupils are widely dilated. She gives the impression that she is suffering from an intense toxæmia. There has been no evidence of any septic mischief in connection with the uterus. These symptoms gave rise to the suspicion that she might be suffering from acute yellow atrophy, but the jaundice is not nearly intense enough for that.

The red corpuscles number one million. The hemoglobin percentage is 22, colour index therefore 1.1. The leucocytes number 12,000. The blood picture is typical and megaloblasts are very numerous. She has been treated by transfusion and by stimulants, but I fear that prognosis is very grave. (The patient died two days later.) One cannot resist the conclusion that in these puerperal cases there is some special toxin which attacks the bone marrow. The increase in the number of leucocytes is nearly always present in these cases, and indicates the presence of an acute toxin. The prognosis is very serious, but if the patient can be tied over the acute onset, I think that the ultimate prognosis is much better than in the ordinary case. At any rate I know of two cases at least where the patients were very ill indeed during the puerperium, where the blood picture was a most alarming mixture of megaloblastic anæmia and leucocytosis, and where life was almost despaired of, and yet recovery took place, and there has never been any relapse, although several years have elapsed. Perhaps a word of caution is necessary here. Severe secondary anæmia is not very uncommon in the puerperium. This may be due to sepsis, and however unpopular such a diagnosis may be with the practitioner, it may be very important to the patient, since it must be met by vigorous antiseptic treatment. The colour index is less than 1. When nucleated red cells are present they are almost entirely normoblasts until near the end in the fatal cases. Poikilocytosis and polychromasia may be marked features, but the average size of the corpuscles is not increased.

In conclusion, pernicious anæmia is a disease which must be looked for. The diagnosis may be obvious, but on the other hand a large number of symptoms—vague ill-health, chronic dyspepsia, cardiac debility, pigmentation of the skin, changes in the urine, neurasthenia, neuritis, spinal sclerosis, mental derangement and a host of others may be due to the same condition.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by M. Castaigne, M.D., Physician to the Beaujon Hospital. Subject: "Bronchial Dilatation."

ORIGINAL PAPERS.

AN INQUIRY INTO A DEATH AFTER TWO INTRAVENOUS INJECTIONS OF SALVARSAN

By Dr. F. J. WALDO,
H.M. Coroner for the City of London and Southwark.
Reported by J. S. WARRACK, M.A., M.D.,
D.P.II., Barrister-at-Law.

On March 20th, 1914, and on adjournment to April 3rd, 1914, Dr. F. J. Waldo held an inquest touching the death of S. W. White.

Mr. F. D. White identified the body as that of his son, S. W. White. Deceased was aged 23, and in good health up to a year ago, when he was treated by his doctor for "abcess in the passage of the appendix, and later of the penis. Deceased was under treatment for nine months. Six months ago he had a "breaking out on the skin," and a
month ago a “breaking out on the mouth.” Deceased stated to witness that he had not had sexual intercourse for some time. A doctor advised him to go to St. Mary’s Hospital for inoculation treatment, and deceased went there three weeks ago. Deceased had two injections there, at an interval of ten days between them. Two days subsequent to the second injection on March 10th, deceased returned to business. On March 11th, he was looking white and shaky, but clear mentally. When he came out of hospital after the second injection he looked “pale and shaky” and had head pains, had vomited in hospital, could not take his food and felt generally unwell. Witness subsequently saw deceased in Guy’s Hospital on March 13th, unconscious. Deceased died on March 14th.

Arthur Turner, a clerk to deceased’s employers, deposed that deceased on March 13th, as he came into the office, had fallen down three steps and grazed his arm. Witness was instructed to take deceased to a local doctor. When the taxicab was in Lombard Street, deceased started shaking, and his hands went up and down. Witness thought deceased was in fits. Witness subsequently saw deceased by removal to Guy’s Hospital. Witness and the constable took deceased there. Deceased was admitted.

P.C. Haswell corroborated last witness, and stated in addition that deceased was unconscious, his eyes were fixed and staring, he was foaming at the mouth, and there was a slight stain like blood on it.

Dr. F. G. Richards, a house physician at Guy’s Hospital, deposed. Witness first saw deceased on Friday afternoon about 1.30 p.m. Deceased was delirious. There was blood-stained froth on the mouth, the tongue not bitten, no vomiting; pupils widely dilated, both equally; at first reacted very little to light. Deceased’s limbs were moving about, and there were convulsions. Witness subsequently obtained information from St. Mary’s Hospital about two intravenous injections of salvarsan, .6 gramme each time, as treatment for syphilis.

Cerebro-spinal fluid was let out by lumbar puncture. This fluid was examined. It was clear, and the result of the examination indicated that suppurative and tubercular meningitis could be excluded. The fluid, however, gave the Wassermann reaction. Cerebro-spinal fluid to the amount of three-quarters of a pint was removed at about two-hourly intervals, in large quantities, with relief to the symptoms that had occurred in the interval. Patient died at 3 p.m. on Saturday afternoon, March 14th. A post-mortem examination was made by Dr. Herbert French at which witness and his colleague, Dr. Berry, were present. The post-mortem examination showed no marks of violence, but a puncture wound at the bend of the left elbow. The heart was healthy. There were three or four petechial haemorrhages beneath the pericardium. There was no pneumonia or pleurisy, but multiple diffuse haemorrhages beneath the pleura and in the mediastinum, blood-stained mucus in the tubes. There were numerous submucous haemorrhages in the oesophagus, but none in duodenum, jejunum, ileum, or large intestine. The stomach was opened and preserved, but the contents were lost. There was blood-stained fluid in it. The liver and gall-bladder were normal, as also the kidney and ureters, and suprarenal bodies. The spleen was a little enlarged.

The brain showed an extreme degree of bright red injection of vessels in pia arachnoidea. The grey matter was also pinkish from hyperemia. There were no meningitis and no haemorrhages.

There was a very tiny scar on the penis, not directly pointing to syphilis. There was no syphilitic lesion in any part of the internal organs, nor any external evidence whatever of syphilis noticed.

Witness was of opinion that there were certain risks attaching to the treatment of salvarsan, which was an arsenical compound, and killed the special germ which exists in cases of syphilis.

There was danger in the way of giving it. Everything had to be done aseptically, and patients being treated by it should be kept in bed. From witness’s knowledge of the symptoms, and the appearances post-mortem, he considered deceased died from arsenic poisoning due to treatment by salvarsan. The congestion of the brain, and the haemorrhages found in the pleura and pericardium, were consistent with poisoning by arsenic. They had only had this one case at their hospital.

Dr. P. H. Bell, clinical assistant at Guy’s Hospital, deposed that he was present throughout the post-mortem examination, and agreed with what last witness had said. The fluid in the stomach was altered blood.

By the jury: Syphilis could not of itself cause the condition found or noticed in the brain. The condition was that usually found in cases of salvarsan poisoning.

Dr. G. H. Garlick, Resident Medical Officer to the Inoculation Department at St. Mary’s Hospital, deposed that he had been five months in that position. He had been told to write to deceased’s family to come for treatment. Dr. Fleming, of his department, did the Wassermann reaction. It was positive. A negative reaction did not always mean “no syphilis.”

Witness made the first injection of .6 gramme of salvarsan into the vein of deceased on February 28th. There was no contraindication. Deceased was kept two nights in the hospital. He left quite well, and witness directed him to come again, which he did, on March 10th. The same amount was then injected, and deceased was kept in one night, and directed to come a third time in ten days. Witness next heard deceased was in Guy’s Hospital. He had heard the evidence already given, and considered that the salvarsan had acted as a poison and been the chief factor in deceased’s death. From what he had read and heard, he considered that the signs found post mortem were consistent with poisoning by salvarsan.

Witness was of opinion that the new treatment for syphilis was very efficacious, and more quick than mercury, and exists under no risk. There was a risk in treatment by salvarsan. Neo-salvarsan was considered by them in their hospital to be more toxic in its effects, and not so efficacious. He would personally tell his patients there was some little risk. He could not say if deceased were told, but he had asked Dr. Fleming, who said it was his habit and custom to warn patients of the risks before injections.

By the jury: He had examined deceased himself, and had satisfied himself that deceased’s kidneys were normal.

The Coroner adjourned the inquest, in order that a chemical examination of the viscera might be made, till April 3rd, 1914.
Dr. F. Womack, of St. Bartholomew's Hospital, deposed to having received two jars containing viscera for chemical analysis. One jar contained a portion of the liver, one kidney, and the spleen. In the other were the stomach and a portion of the small intestine.

It would have been desirable to have had the stomach contents and he would have liked portions of many organs, but owing to the intravenous method of administration there would be less arsenic in the stomach than in the glandular organs. Some arsenic would be excreted by the stomach, and some by the liver and kidneys.

He had duly examined the viscera sent for analysis in this case. The liver contained 28 parts per million of arsenic, or a total quantity in that organ (taking the weight as 55 0zs.) of 0.71 grain. The spleen contained only 0.0072 grain. The two kidneys contained 0.014 grain. The blood which had exuded from these viscera into the bottle in which they were contained showed nine parts per million of arsenic. There were traces of arsenic in the stomach, membrane and intestine. He concluded that in the interval between the second injection and death, a good deal of the arsenic had been eliminated by the kidneys, more than half, less by the liver and stomach. In his opinion the cause of death was acute arsenical poisoning resulting from the injections of the organic compound known as salvarsan.

There had been very few deaths from salvarsan poisoning in England, but many more abroad. There was a close accord of the symptoms in this case with those recorded in available literature. This case was the first of the kind witness had had to deal with as analyst. He should say there had been 150 fatal cases since the end of 1910, when the drug was introduced, throughout the whole world. The majority of deaths were due not to arsenical poisoning, but to maladministration, or bad technique. There had been extremely few cases in England. Arsenic was a very potent drug, and very toxic, and there seemed to be an idiosyncrasy—an unusual susceptibility to the drug—which some people showed. Witness thought this case was undoubtedly one of idiosyncrasy. The non-poisonous character was probably due to non-solubility in the blood in some; in others the solubility in the blood was greater. In the latter cases the abnormality of the blood, this special susceptibility was not to be anticipated. Thus the effect would be that of an overdose.

There were two theories: (1) Ehrlich, Spirilla killed in the blood set free endotoxins. (2) Major Gibbard, A special susceptibility to the drug.

There had been cases with symptoms similar to this one, such as cloudiness of mind, and indistinctness of speech. These cases usually occurred after the second injection. Arsenic was a cumulative poison, and the drug was not completely eliminated from the system before the second injection was given. There might be more sensitiveness to the second injection.

Neo-salvarsan was given at St. Bartholomew's Hospital almost invariably. It was as efficient and efficacious, more soluble. It could be given more concentrated. It was less dangerous, troublesome, and took less time. There had been 750 cases there without any death, or any untoward symptoms.

Ehrlich had mentioned 10,000 cases, with four deaths and three of these were in a very serious state and likely to die apart from arsenic.

The salvarsan treatment was efficacious, but he believed the new treatment was more efficacious, and had almost replaced salvarsan. Witness did not think 0.6 gramme an overdose. This was an ordinary dose, unless contra-indicated by symptoms such as in the kidneys.

Mercurial treatment was carried on afterwards, nine or ten repetitions spread over more than three months. This treatment was largely given in the Army and Navy.

The probability was that deceased had four grains in his body. In the organic compound the arsenic was less toxic than in arsenious oxide. The lethal dose of arsenious oxide by the mouth he had known to be 2 grs. only.

If arsenic was taken by the mouth into the stomach, the effects were mostly found in that organ and in the intestine. When administered intravenously, petechie and hemorrhages would be found.

Serious symptoms would appear a day or two after the second injection, such as paralysis, mental symptoms, indistinct speech, sweats, vomiting, fits, and might resemble meningitis. It was most important that the salvarsan should not be dissolved more than the minimum amount of time. It underwent oxidation. It should be made up immediately before use. And as to the technique, the distilled water and salt solution must be used quite fresh and the salt be chemically pure sodium chloride. Certain special skill was required in the administration and by qualified medical men only.

Witness agreed with the Coroner that the operator at first should have some more skilled person present. The treatment was expensive, and the Wassermann test should be performed beforehand.

Witness had read the depositions and thought that death was due to an unforeseen accident. He considered the injections were given in a skilful and proper way.

Salvarsan was a patent. It contained 30 per cent. of arsenic, which was the poisonous element. Benzol was also a constituent.

In reply to Dr. Richards, who asked whether witness thought that arsenic as arsenic, or that salvarsan as salvarsan caused death, witness replied that he attributed death to the organic compound rather than to the arsenic, but in chemical analysis only arsenic was recovered by the chemical tests. Salvarsan was one of the most valuable medical discoveries in recent years.

The medical witnesses agreed that death was due to the poisonous effects of the compound salvarsan rather than to the arsenic.

The learned Coroner, in summing up, recapitulated the evidence, pointing out to the jury that they had to determine how deceased came by his death. They might have to decide as to whether there was any neglect by some person or persons, but there was clearly no evidence of negligence. The drug was a useful one. There were no contra-indications to its administration. It was given in a very careful and skilful manner by an experienced medical man.

A verdict of death by misadventure from acute poisoning consequent on two intravenous administrations of the compound known as salvarsan was returned, the jury adding that the salvarsan...
was skilfully given, and that deceased was properly treated at St. Mary’s and Guy’s Hospitals

LITTLE’S DISEASE AND ITS SURGICAL TREATMENT.

By M. Savariaud, M.D.,

Surgon to the Trousseau Hospital, Paris.

[Specially reported for this Journal.]

By the term “Little’s disease,” or, rather, “Little’s syndrome,” we generally understand a congenital form of spasmodic paralysis especially prone to attack the lower limbs, in other words, paraplegia, associated with spasm and contracture present at birth. It may happen, as with so many other congenital affections, that the symptoms are not very striking at birth; indeed, it is rare that the diagnosis can be made at that stage, since the newly-born, especially those born before time, are normally rather stiff. It is only after a time that the mother or the nurse is struck by the third member being the one that troubles entailing in dressing and washing the infant.

The rigidity is most marked in the lower limbs, which are contracted either in extension or flexion. But always in adduction, so that the two limbs cross each other. If we try to separate them the infant resists and screams. As a rule the child cannot sit up since it is “all one piece.”

The disease may be limited to the lower limbs, but in some instances the upper limbs are affected, usually one more so than the other. The forearms are bent at a right angle, the elbows brought close to the trunk, the hands in forced pronation, the fingers more or less distorted and unable to grasp anything. The child “speaks through the nose” and is barely intelligible. There may be squint and disturbances of deglutition. The contracted muscles are also paralysed, though there, as a rule, more contracture than paralysis, but the contrary is sometimes met with.

It is met with in every degree of severity, according to the extent and severity of the paralysis and the degree of cerebral involvement. The mildest form of the disease is characterised by mere difficulty of walking due to contracture of the muscles of flexion and adduction. The little patients hop along on their toes, with the knees slightly bent and knocking against each other in walking, the active limb describing a segment of a circle round the other limb. In these cases the upper limbs and the intellect are unaffected.

In a second degree walking may still be possible, but it is difficult, and one arm is usually affected. In the third degree walking and the erect position are impossible, and sitting is only practicable by the aid of sundry devices, as for instance strapping the trunk to the back of the chair. In the fourth degree both the upper and lower limbs are paralysed and contracted, and the sufferers are quite impotent, being unable to feed themselves or to hold a pen, and intelligence is at a very low level. In the fifth degree the victims are nothing more than paralytic idiots, and the congenital contracture plays quite a subordinate part in the clinical picture.

The prognosis varies greatly according to the extent and the severity of the lesions. In a certain number of cases the contractures diminish to some extent, constituting an improvement or even spontaneous recovery. Other cases remain stationary or gradually become worse. The less the intelligence is affected the greater the hope of improvement.

The pathogenesis of the disease is still ill-understood. There is reason to believe that it is not unique, and that among the patients who display Little’s syndrome we ought to deduct a certain number of cases of Little’s disease, properly so called.

Little’s disease, properly so called, is characterised by premature birth, rigidity of the limbs, and spontaneous improvement. This affection seems to be consequent upon arrested development of the spinal cord, more particularly to delay in the myelinisation of the pyramidal tract. This variety, however, is very rare, indeed its existence is denied by some.

Alongside this type of Little’s disease are innumerable forms of spasmodic paralysis, more or less congenital, due to cerebro-spinal lesions consequent upon a laborious confinement. The obstetrical traumaism acts by compression, constriction and asphyxia, giving rise to cortical haemorrhages followed by sclerosis and secondary degeneration of the pyramidal tracts. Syphilis and alcoholism on the part of the parents play a predisposing role.

We now come to the treatment of these subjects, and inter alia the question arises, What can surgery do for them? From this point of view our division of the cases into several categories comes in useful. Let us commence by discarding the really desperate cases and the very mild cases, and then we will see what can be done for the others.

Desperate Cases.—The degree of contraction and the multiplicity of the lesions do not render treatment difficult, but what really makes the case hopeless is not so much the state of the limbs as that of the brain. With a normal or approximately normal brain we are entitled to hope much; with a greatly damaged brain it is better to hold our hands.

Very Mild Cases.—Here is a child whose only trouble is that he has a rather hopping gait, his weight only bearing on the anterior heel. Now such the tenotomy of the tendo Achillis is here all that is required to restore equilibrium.

Medium Cases.—These are more difficult cases. The patients walk only with the greatest difficulty, propping themselves up by leaning on the furniture, or indeed they may not be able to walk at all. The legs are crossed in bed and are permanently displaced, the knee is bent, the feet are in varus equinus or valgus, in short no normal prop is available.

In such cases the first thing to be done is to straighten the limbs in order to provide a normal prop. Certain tenotomies or muscle elongations will be necessary, after which the limbs are maintained in hyper-correction for six or seven weeks. In the lower limb, for instance, we shall perform tenotomy of the tendo Achillis elongation or tenotomy of the hamstrings and adductors and of the tendons inserted on the iliac spine. The patient is then placed in a plaster apparatus for a couple of months or so with the legs well separated in extension and external rotation and the feet in hyper-extension.

If, after this operation, the feet still tend to become deviated, the tendency must be overcome by transplantation of tendons. When the limbs are in good position it remains for us to train the patient in the movements required for
walking. We may commence by making him execute simple movements in bed—raising the limbs, flexion, &c. Then he is put on his feet and encouraged to try to walk, movement by movement, the weight of the body being supported by assistants or parallel bars.

Two things may now happen. In the first the spasm may be slight, or at any rate not extreme, and with time one may hope that it will diminish. In this event all we have to do is to continue the course of training with all necessary gentleness and patience.

In the other case we find that the spasmodicity and contracture are such that we make no headway. If this be so, rather than give up the case, we should be justified in performing Forier's operation, which aims at diminishing the reactivity of the spinal cord by dividing a certain number of the sensory roots of the lumbar and sacral nerves \((L_1L_2L_3)\) inside the sheath of dura mater. No doubt this is a big undertaking, but it is so effectual that we must not hesitate to have recourse thereto in a case in which it is worth while. For that matter the gravity of the intervention may be reduced by attacking the nerves of the cauda equinus where they come off opposite the lumbar enlargement. This greatly simplifies the operation. I performed this operation on a child of seven in whom all the ordinary modes of treatment had failed, and the improvement, which so far had been nil, on account of the excessive reactivity of the cord, made rapid progress after the operation. The spasmodicity of course did not entirely disappear, but it did so to the extent of at least three quarters forthwith, and has gone on diminishing since. A year has now elapsed since the operation, and thanks to tonomoties, transplantation of tendons and patient re-education, the patient is beginning to walk, very imperfectly no doubt, but still in an encouraging way. By holding on to articles of furniture he can find his way round the room. For a normal child this would not be anything to be proud of, but it is a great deal for a child who had never left his bed.

I hold that Forier's operation has been of the greatest benefit, and that in presence of such a terrible disease we must be satisfied with having accomplished thus much.

**FIVE CASES OF STRANGLATED HERNIA IN INFANTS, WITH AN ACCOUNT OF A RAPID AND EFFICIENT SURGICAL PROCEDURE.**

By JOSEPH BOYD BARRETT, M.D., B.Cr., Assistant Surgeon, Children's Hospital, Temple Street, Dublin.

I have adopted, and intend to practise, a procedure for the cure of strangulated hernia in infants, which differs considerably from the ordinary routine operation. In brief, I think it is wise and quite unnecessary to isolate and ligature the delicate sac of a hernia in an infant, a procedure which must involve injury to the delicate spermatic cord. Further, the suturing of the external oblique fibres forming the external ring is also omitted. It is only necessary to define the internal oblique and conjointed tendon and to suture both to Poupard's ligament, and then carefully to approximate the skin, preferably by sub-cuticular silk-worn gut. This can be done very rapidly.

The operation has certain merits. It is a neat operation; it involves no injury to the cord; there is no mauling of the tissues. The presence or absence of the sac, and the suturing, or not, of the thin and weak fibres of the external oblique have no influence on the return of the hernia. If the internal oblique and conjointed tendon are properly sutured with medium silk sutures to Poupard's ligament the hernia cannot reappear. The cure is a permanent and radical one. The neatness and quickness of the operation is in the utmost advantage to the child. There is no post-operative shock and no possibility of damage to the cord or testicle.

What happens to the sac? I believe it disappears. When one remembers that the tunica vaginalis is patent at birth and communicates with the peritoneal cavity of the abdomen, there is no reason to expect that an empty sac will persist, and the opening made is it for the reduction of the intestine prevents the accumulation of fluid.

It may be argued that when one has a finger in the sac it is very little trouble to "wipe off" with a sponge the coverings and the spermatic cord. This is not denied. It is not a matter of difficulty, but it is unnecessary and must involve, however carefully accomplished, some injury to the cord. That it does so, even in cases that are not strangulated, is evident from the edema of the testicle which so often follows this procedure in children. It is the most tedious part of the operation. It is dangerous to do it quickly. It involves waste of precious time. It is of no advantage.

The aetiology and treatment of strangulated hernia in infants are very cursorily dealt with in the text-books. It is usually stated that they differ in no matter of importance from similar conditions in adults. There are, however, many differences:

1. Strangulation in children usually occurs in large hernias. In adults the opposite is almost the rule, except in elderly subjects with large scrotal or umbilical herniae.

2. Hernias in infants never contain omentum. The omentum in a child is small, and its fat contents quite insignificant and without bulk. (It is owing to the small size of the omentum in young children, and its inability to wall off an abscess that appendicitis in children demands immediate treatment.)

3. Adhesions in the sac in a child are extremely rare. I have only once seen adhesions, and they occurred in a remarkable case of congenital hernia on the left side, in which I found the appendix attached by two bands to the left testicle. It must not be inferred from this that manipulation may be used indiscriminately in attempts to reduce a strangulated hernia in an infant. Such a procedure usually results in the formation of hematoma in the bowel wall; and, further, owing to the rapid filling of the sac of a strangulated hernia in an infant with serum, haemorrhage may be expected in reducing the contents. If, then fluctuation is present, manipulation can only do harm; an operation is imperative. In none of the cases under my care was it possible to reduce the intestinal contents until the internal ring was enlarged.

4. In infants and young children all inguinal herniae are oblique. A direct hernia is an impossibility. This is of the utmost importance to remember when brought to deal with a strangu-
lated hernia in an infant, because the internal ring must be opened in an outward direction. (This is best done by a Lane’s scissors.) There cannot be a direct hernia in infancy because the inguinal canal has no length. The external and internal rings are superimposed, almost completely. As the pelvis widens the rings separate until the adult proportions are reached. When the two abdominal openings are almost superimposed, a hernia must pass through both. This being so, the internal ring may be divided in an outward direction without fear of wounding the deep epigastric artery.

(5) The necessity for immediate operation and the importance of a rapid and neat operation. These are only comparative differences from the treatment of strangulation in adults. They are, however, worthy of emphasis. An immediate operation is necessary in order to avoid the possibility of having to resect a gangrenous portion of intestine, a proceeding usually attended with fatal results in infancy. The importance of a neat and rapid operation is greater in children owing to the danger of post-operative shock, a condition easy to avoid but difficult to treat.

(6) There are two points worthy of consideration as regards the skin incision—the position of the incision and the suturing of it.

The incision should be kept as high as possible. This is best accomplished by having the external half of Poupart’s ligament and the internal half horizontal above the level of the iliac spine. It well repays to take the utmost care with the suturing of the skin wound. It is vain to rely on dressings to keep the wound clean, and owing to the habits of infants the edges of the wound should be approximated with the greatest care. If this be done and the incision be made at a high level the chances of rapid healing are increased.

The ages of the cases under my care varied from six months to one and a half years. They all recovered from the operations without any post-operative shock. In one case, the hernia recurred in an infant of 1 year, act. 11, who had developed strangulation when suffering from a circumcision which had become septic. The hernia wound became infected, and I had subsequently to remove the deep sutures. The child is now quite well and an operation will be done later for radical cure.

The hernias were all of the acquired variety. (Congenital hernias form a very small proportion—89%—of hernias in children.) They were all large in size, and contained small intestine. The duration of strangulation could not be accurately determined in each case. One gave a history of eight hours, another of twelve, and another of twenty-four hours. In no case was the canal gangrenous; nor did the constricted portions give any cause for alarm when examined. The normal appearance of the bowel, apart from haematomata which had developed, rapidly returned when doused with hot saline.

The duration of the operations from the time of the first incision varied only with the delay in douching. The shortest time was nine minutes, and the longest fifteen minutes. The operations were performed in the Children’s Hospital, Temple Street, Dublin, and I am indebted to Dr. M. F. O’Hea and Dr. P. T. O’Farrell for their able assistance in most of the cases. The anaesthetic used in every case was ether given on an open mask.

In order to shorten the time of the operation, the anesthesia is not begun until everything and everyone is in readiness, even the needles being threaded. The first portion of the operation, up to the examination and return of the intestine, does not differ from that usually performed for adults, with the exception of the method of enlarging the internal ring.

When the bowel is returned, the internal oblique and conjointed tendon, and Poupart’s ligament are rapidly defined by blunt dissection. A good portion of muscular belly is then united to the full depth of Poupart’s ligament, over the sac and its coverings, by usually three medium silk sutures. The skin edges are then rapidly and carefully approximated by fine silkworm gut (preferably a sub-cuticular suture) and the operation is complete.

This operation can be done very rapidly and neatly, and is quite sufficient. The tedious and unnecessary portions of the ordinary operation are omitted. The external oblique in an infant is composed of very feeble and delicate fibres. Their approximation is superfluous. They have no strength, and can offer no resistance.

The sac in an infant is an extremely delicate membrane. The ligaturing of the sac is of no avail if the conjointed tendon is not united to Poupart’s ligament. If the latter structures are carefully approximated the sac may be left; for, if no hernia can possibly return, and, furthermore, by this method there can be no damage to the cord or testicle, the shock which is attributed to manipulation of the cord is avoided, and there is a valuable saving of time. This simple operation does not exhaust the patient, and if it prove as efficient as I confidently anticipate, I may perhaps be pardoned for recommending it for trial.

OPERATING THEATRES.

HAMPSTEAD GENERAL HOSPITAL.

FRACTURED SKULL.—Mr. Jackson Clarke operated on a female child, act. 2, who had fallen out of its mother’s arms at the top of a staircase, falling at the bottom of the flight on to its head. When the patient reached the hospital she was conscious, and had paralysis of the right hand and forearm. There was a haematoma-like swelling crossing the vertex from ear to ear, and on palpating this a fissure in the skull was felt.

The child was anaesthetised, and an incision made corresponding with the extent of the swelling. This revealed a fracture of both parietal bones, and went to a quantity of blood and a considerable amount of brain matter in small floculi, the dura mater being torn in the whole extent of the fracture. The latter was quite half an inch in width, and it expanded and contracted with the respiratory movements of the child. Two drill holes were made, one on either side of the fracture, and a silver wire passed and twisted; this brought the bones into firm apposition. The skin wound was then closed.

The patient recovered from the anaesthetic and made an uneventful recovery. In the course of the four weeks following the operation the paralysis of the right hand and forearm gradually diminished. This improvement has continued up to the present time, some eight months after the operation, the child using its right hand freely, but the grasp is still slightly weaker than that of the left side. Mr. Clarke said that he estimated the amount of brain lost was fully half an ounce, most of it appearing to come from the left parietal lobe. It remained to be seen, he
pointed out, whether any subsequent trouble in the form of Jacksonian epilepsy would ensue. The child is being kept under observation.

The relation of the TUVNOMIUM.—The same surgeon operated on a middle-aged man, who, on alighting from an omnibus, was knocked down by a rapidly moving car, which passed over his body. On reaching the hospital he was found by the House Surgeon, Mr. G. B. Truter, to have a wide separation between the two public bones in front, and also a wide separation at the left sacro-ilac synchondrosis. The general condition of the patient was good, there being no shock. Evidence of extravasation of urine rapidly appeared, and deep large superficial fascia of the abdomen and into the datorious tissue of the scrotum, the latter becoming swollen and dark-red in colour. A five-inch median incision was made, the lower end being just above the root of the penis. The testicle of the left rectus muscle was found to be detached near its insertion; the tendon of the right rectus was partly torn, and both conjointed tendons were also torn from their attachments. A rubber catheter was passed fairly easily into the bladder. The bladder was incised and explored and found to be intact. A hole was then drilled through each public bone, and a very stout silver wire was passed, and this was drawn taut and twisted, bringing the two public bones into close apposition. A rubber catheter was tied in, and a large rubber drain placed in the bladder wound. The incision was then closed except around the bladder tube and also where the silver wire protruded, this last being left long. A second incision was made into the lower part of the scrotum. The patient rallied well from the operation, his pulse being good throughout. An aspiration syphon was introduced into the bladder tube, and by this means the bladder was kept empty. After six days the larger tube was removed. The smaller one of the syphon apparatus being left in the bladder.

Mr. Clarke said that it was evident that there was rupture of the membranous urethra in this case, and it was not clear how the bladder drainage could be discontinued: for this he would allow at least fourteen days. When the bladder wound was healed and the urethra working well, the steel wire would be either cut short at the surface of the rubber bougie, or it would be pulled out and the bone, it would be removed entirely. As to the sacro-ilac synchondrosis, if any weakness should remain there, Mr. Clarke contemplated uniting the bones by one or two large screws at a later date.

TRANSACTIONS OF SOCIETIES.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JUNE 11TH, 1914.

MR. T. P. BEDDIES, F.R.C.S., IN THE CHAIR.

DR. H. C. SAMUEL showed (1) case for diagnosis. The patient, a middle-aged man, came two hours ago with an eruption of papular nodules and papules, some of which were aggregated on the neck. There were discrete lesions of similar nature on the face and forearms, and a semi-papular one on the leg. He considered it a drug eruption, possibly iodide, though there was no history of that having been taken nor was any found in his urine, which had just been tested. He had been recently having medicine from his doctor, and which had a bitter taste. It had come out too suddenly for it to be a phthisis. He had not yet learned the result of the Wassermann test. It might be a toxic erythema.

He next ventured to give a positive diagnosis, that of a drug eruption was largely favoured. (2) CASE OF BROOCH'S PARAPSYRIOSIS EN FLAGE. He said Brooch originally described the condition as "erythrodermie disseminée pityriasis."); it was very resistant to treatment. This patient, a man, had had the condition four years. One could see some sharply defined macular oval patches, somewhat resembling seborrhoea and slightly scaly with no infiltration. Anti-seborrhoeic treatment had no effect on the lesions. Sometimes these cases were referred to as cases of pityriasis persistenta of Crocker. This case differed from those hitherto described in that pruritus was marked. The patient was being treated chiefly for the intense itching, and X-rays seemed to have benefited the pruritus. The patient had been treated with wide-spread X-rays for, what the speaker thought might be a pemphigoid condition, but there was no infiltration and the sections did not show evidence of premorcyosis; there was only dilatation of the endothelial bloodvessels. The Kromayer lamp (mercury vapour) had been tried, but had been found rather loosely. The case shown to-day was only one variety of the condition. The cases which had a chronic resistant scaly erythrodemia and did not respond to treatment had been grouped together and, following Broc, had been called parapsoriasis. But some distinction should be made. What were the lesions of parapsoriasis understood to be? He thought they were the very chronic lesions which resembled either seborrhoea dermatitis, pityriasis, pityriasis rosea, or the pre-mycotic stage of mycosis fungoides, or a fading lichen planus. This present case much resembled seborrhoeic eczema, but there were some cases of pityriasis lichenoides which might not decide whether the condition were lichen planus or psoriasis. The Kromayer lamp was used here not so much with the idea of attacking the parapsoriasis itself, but in order to control the intense pruritus which, he said, had been, was such a marked feature in this particular case.

DR. G. W. SEQUEIRA said he had seen many cases of parapsoriasis, but it was the first he had seen in which there was much itching. He would defer his diagnosis for the time being, being an early stage of mycosis fungoides had to be considered.

DR. J. GALEBRAITH said parapsoriasis usually itch, more or less, which it had, and it had reacted well to X-rays—hal a pastille dose once a fortnight, or a full pastille once a month, repeated three or four times if necessary. Sections of parapsoriasis showed thinning of the prickle layer, and a characteristic feature was the almost absence of the inter-papillary processes and the stretching out of the papillae to form a wavy line with the epidermis.

DR. W. J. MIDELTON said the case of interest to him because of the treatment—i.e., the profound laminae Kromayer administered by the patient. It had been thought by some that there was some specific action exerted by the ultra-violet rays, but he regarded it from the standpoint of the hyperemia caused thereby. Enough was not yet known as to the exact mechanism of action into which it was when hyperemia was produced, but the most people acknowledged its benefits, whether produced by a mustard plaster, or by a lamp costing £25.

DR. J. D. P. MCLATCHIE showed a case of pityriasis rosea in a well-developed young man.

DR. SAMUEL said he thought all would agree that the condition was pityriasis rosea, with which the distribution corresponded. This distribution, he considered, must be determined by the vest, or other article of clothing that was worn, and he had often noted its association with pityriasis capitis. This patient said he had always a "scaly head." Usually it was said not to have any connection with seborrhoea.

DR. C. G. MACK (for DR. Vinarce) showed a case of recurrent alopecia, on both occasions in connection with licea tonsurans.

DR. SAMUEL did not doubt the diagnosis, but thought it was not impossible that the alopecia might have been caused by the licea. The patient had, last week, when three young sisters came up. One had a typical lesion, due to the eczothrix. The second sister had ordinary ringworm, also due to eczothrix. The third sister had a patch of clinical alopecia areata, but in view of the other cases which were observed, it was made, and one stump was found which, on treatment with potash, revealed typical eczothrix.

DR. GALEBRAITH said he did not think there was any connection between ringworm and alopecia, but in all
The case one would find the acne bacillus, though sometimes in the hand form in children it is absent. Some cases had, in his hands, responded remarkably well to vaccines when ordinary treatment had failed. Excluding the cases in which a nervous lesion could be involved, there were, in the year when it was traced in all cases of alopecia with the acne bacillus, none, in respect to the present case, recurrences were common.

Dr. SECHEK, some years ago, he showed a connection at the late Sir Jonathan Hutchinson clinic of typical alopecia areata, and Sir Jonathan said there was no doubt that the wife caught the condition from the husband, probably through leaning back in the same chair. There were no signs of tinea; it was evidence of alopecia areata.

Dr. NORMAN MACHEN showed (for Dr. Alfred Eddowes) (1)

A CASE OF GUMMATA OF BOTH ALÆ NASI

in a female, aged 50. Before coming under his care the patient had been treated by X-rays, probably under the mistaken idea of the antisyphilitic treatment, and it did not yield to the X-rays. There was no indication of tubercle. But the treatment had been rather short for such improvement in tubercle—namely, a month's treatment with mercury and iodide. Treatment of rectal syphilis by suppositories was a good method, the average dose being 15 grs. of mercury a day.

(2) A case of eczematous impetigo—or chronic staphylococcal impetigo—in a gardener. The condition began as a small abscess which had been punctured. Such cases appeared to be common this year.

Dr. GALBRAITH said the case might be called an eczema in the ordinary sense, but it seemed to be a pyogenic infection. It was likely that staphylococcus was the causal organism. It was the kind of chronic eczema in which a vaccine seemed to act like magic; half-a-dozen injections or so of an autogenous vaccine would probably clear it up. Locally he would use only a mild antiseptic ointment, such as weak ammoniated mercury.

(3) Case of Lupus erythematosus of the face in a girl, aged 13 years, of three years' duration. He diagnosed the condition which should be called central atrophy. She also suffered from chilblains during cold weather. When a persistent lesion for over a year occurred on the face, whether of a child or an adult, and it looked seborrhoeic, one had to be careful about calling it eczema. The child's father died of phthisis.

SPECIAL REPORTS.

ROYAL COMMISSION ON VENEREAL DISEASES.

At the forty-third meeting of the Royal Commission on Venereal Diseases evidence was given by Dr. J. J. Pringle, physician in charge of the skin department of Middlesex Hospital and president of the Dermatological Section of the Royal Society of Medicine. He stated that of 36,451 cases of skin disease dealt with in the out-patient department of the Middlesex Hospital during the last 25 years, 1,853, or rather over 5 per cent., presented indubitable evidence of syphilis. He did not represent the number of patients who had attended the hospital for syphilitic manifestations, but only those who had been referred to the special department as suffering from some affection of the skin. Of the 1,853 cases of syphilis, 945 were males and 908 females. Dr. Pringle thought that this apparent equality of incidence in the two sexes was due to the fact that men do not willingly attend hospitals during working hours, except for diseases which in their opinion threaten life or cause grave discomfort or pain. On the other hand, anything causing disfigurement impelled women to seek medical advice. Of the 1,853 cases of syphilis already mentioned, nearly 24 per cent. were foreigners.

Dr. Pringle stated that he could not see his way to support or advocate any measure of compulsory notification of venereal disease. The medical profession was, he thought, practically unanimously opposed to it, and even if it made confidential its effects, the public would be merely to drive them to seek treatment from unqualified persons.

Experiences both in hospital and private practice convinced him that much of the prevalence of syphilis in England was of foreign importation. He believed that a considerable number of prostitutes left their own countries because they were unable to ply their trade there, and came over to England and spread the disease in this country. It was important that this matter should be further investigated and that steps should be taken to deal with it.

THE CARE OF CHILDREN UNDER SCHOOL AGE.

The last of three lectures given under the Chaddock Trust was delivered at Leeds Town Hall on Saturday, June 27th, by Dr. Joseph Cates, Medical Officer of Health, St. Helens, who outlined a comprehensive scheme of public health reform. He said that there were already far too many agencies attempting to deal with the health of the community. Efficiency, economy and public comfort demanded that all matters directly relating to public health should be administered and controlled by one central department acting through the councils of the counties and county boroughs. Health authorities would then for the first time be in a position to grapple with the beginnings of the matter, instead of being in a position to afford assistance to those who were already too ill to be helped. It was essential, therefore, that public health authorities should be able to provide adequate centres to be established throughout the country by public health authorities. To these centres expectant mothers would come for help and advice, and, in order that a knowledge of suitable cases might be obtained, midwives should be required to notify to the medical officer of health their engagement to attend an expectant mother.

The pre-natal benefit provided by the National Insurance Act would be replaced by an adequate grant to every mother coming within a certain income limit, and the administration of the benefit should be carried out by the health authorities. In conjunction with the scheme of public health, pre-maternity and lying-in wards for patients, married or otherwise, were required to require institutional treatment. Infant consultations and baby clinics were urgently needed for the examination and treatment of children under school age. The lecturer said that where the home circumstances were unfavourable or the mother was industrially employed, the crèche, and later on the nursery school, would train and protect the growing child.

Referring to the establishment of municipal milk depots, Dr. Cates emphasised the advantages to be gained from the use of dried milk. The experience of Leicester has shown that it was easily digested, less liable to contamination in the home, economical in use, and could be extensively employed with the most successful results.

Alluding to the difficulty encountered in obtaining early treatment of disease, the lecturer said that it was high time that the medical benefits of the National Insurance Act were extended to the majority of insured persons, and the scope of the benefits were made to include the treatment of conditions such as decayed teeth and defective vision. The prevalence of venereal disease, its importance to public health, and the tremendous expenditure incurred in the maintenance of lunatics, demanded that by a vigorous campaign local health authorities should attempt to eradicate the disease. Free facilities should be provided for diagnosis and effective and prompt treatment.

FORMS OF MENTAL ANOREXIA.

Anorexia is less a malady than a syndrome, common to several affections. Its clinical forms are diverse.

HYSTERICAL ANOREXIA.

The most frequent form, described years ago by Gull under the name of hysterical anorexia, is anorexia observed in young girls having in their ascendants some mental disturbance (alcoholism, phobia, mental depression, etc.) These subjects present no signs, physical or mental, of hysteria. Unlike their companions, they are grave, object to noisy amusements, are listless, religious, and sometimes mystic; they appear to be older than their age, and, at the moment of puberty, are observed to be sickly, their intellectual faculties diminish and are incapable of any effect even to mastication. At the same time they complain of painful sensations in the epigastrium, although the region is not tender to pressure.

Outwardly these patients present particular characters, the skin is dry, the nails brittle, the hair falls. To this may be added a change in the disposition, which becomes irritable with intermittent attacks of despair, and in exaggerated cases, with ideas of suicide.

The prognosis of this condition is grave. Relapses are frequent, and in some cases the patient falls into a chronic state that may terminate in death.

NEUROSYMPHETIC ANOREXIA.

Anorexia can be met with in certain neurasthenic patients who from infection or grief producing dyspeptic troubles, diminish progressively their food and study the diverse sensations of their stomach. They make up a regular phobia of food and put themselves on the most reduced diet, they lose several pounds in weight, but are easily cured by isolation and psychotherapy.

HYPochondriac ANOREXIA.

In a superior degree, young nervous subjects with some hereditary affection as to charge and disposition; they renounce the company of their friends, seek solitude and pass their time in complete inactivity. They restrain eating because they have lost taste for everything. No happiness exists for them, they have no desire to speak, nor to eat or do anything. This condition may last for months and be succeeded by a form of depressive mania with intermittent attacks of agitation.

ANOREXIA OF EARLY DEMENTIA.

Fear of being poisoned, intoxication for some imaginary fault, fear of eating dangerous microbes, of catching the pretended malady of the person who prepares their food, are among the chief causes observed in persons suffering from mania.

Anorexia resulting from the different mental conditions described, says Dr. Feuillette, is about the same in every case. The consequent emaciation provokes the same cachexia with pallor of the skin, falling of the hair, congestion of the extremities, obatinate constipation, and all the signs accompanying accentuated denutrition. The menses are suppressed and frequently signs of tuberculosis are observed. On this point it would be interesting to know if tuberculosis is the cause or the consequence of anorexias. But, however, to suppose that the organism of such patients being in a state of denutrition bordering on cachexia, furnishes a favourable soil to the development of tuberculosis.

Anorexia of hysteria can be cured by isolation of the patients; the same treatment applies to persons suffering from neurasthenia and melancholia. But anorexia of hypochondriacs and certain melancholics is modified by the affection it accompanies.

The prognosis of anorexia of dementia is rather grave, the patient opposing to all efforts of the medical attendant and the family an indomitable negativism.

GERMANY.

Berlin, June 27th, 1914.

AMONGST the other subjects discussed at the German Surgical Congress was the SURGICAL TREATMENT OF SUPPURATIVE MENINGITIS, by Hr. Barth, of Danzig. He reported three cases which he had successfully treated by laminectomy of the lumbar vertebral column with drainage of the dural sac. The meningitis was complicated by injury of the spinal cord as regarded origin. Staphylococci, diplococci, and streptococci were all found in the puncture fluid. Puncture had been repeatedly made without effect before the operation was performed. The results of recovery in the suppurative meningitis were clearly not so bad as was generally believed, if the disease was taken in time, as the affection began apparently as a diffuse process, and it was only later that encapsulations took place between the cerebral convolutions. People had been sceptical as to operation for two reasons, the affection had been considered incurable, as the end stage had always been kept before the eye, just as had been the case in meningitis after operation. It was not to be forgotten, however, that with gradual advance of the disease a gradual power of resistance was developed through growth of leucocytes. Whilst lumbar punctate in meningitis acted as a bactericide this action was needed altogether in normal cerebrospinal fluid. Diagnosis depended on the presence of poly- nuclear leucocytes in the lumbar punctate, the infective bacteria might disappear under the influence of the leucocytes. Operative recovery was about 50 per cent of the special power of operation in the early disease. The recovery did not so much depend on the bacteriological condition, both cases of streptococci and pneumococci were amongst the recoveries.

Lumbar puncture was called for on the first appearance of symptoms of meningitis. Immediate elimination of primary centres of disease, continued lumbar puncture until relief of cerebral pressure was obtained, then if this did not suffice, drainage of the dural sac through one of the lumbar vertebræ. Murphy drained through the posterior fossa above the foramen magnum. There was now no longer any reason why meningitis should not be treated surgically.

Hr. G. Axshein, Berlin, followed with a paper on the ORIGIN OF FREE BODIES IN JOINTS and their RELATION TO ARTHRITIS DEFORMANS.

The speaker considered the König method of origin of these loose bodies in joints, viz., by a reactive dissecting process as in a joint in which there was disease already established, to be proved. The inquiry into the so-called false stages of the bodies had been striking. Injury to a circumscribed part of a joint led to a regular series of symptomology, local and others of a general nature. The local appearances
of a regenerative nature were the cause of the bodies, the general, which we were not yet thoroughly acquainted with, were similar to those we had been in the habit of wrongly calling arthritis deformans. The local symptoms in a case of ossification of all the cartilage into living fibrous cartilage by invasion of adjoining living cartilage, and, secondly, in the resorbing and dissecrating invasion of the changed subchondral marrow (subchondral dissection). If the process prevailed, there was a complete softening of the circumscribed unhealthy portion of the joint where exfoliation followed as the result of mechanical causes. The primary injury to the joint to be a traumatic accident, the mechanics of injury to the knee joint was almost always the knocking together of the cartilage of the patella and that of the lower end of the femur, by force from the front and side-front. That was understandable as it was here in this exposed spot that cartilage rested on cartilage. This also explained the localization of the disease (60 per cent. the anterior femur surface, 30 per cent. the posterior surface of the patella). This led to the original idea explained the frequency of the affection in both places at the same time. The practical conclusions reached by the reader of the paper were the following—

As from experience we knew that the free body regenerated only one of the disease in the joint the removal of a solitary body was not sufficient. Rather wide opening of the joint was indicated in order that all parts of the joint might be examined in which the bodies were likely to be met with, and any of the cartilage that had been softened might be quickly, be removed. It was only in this way that the injurious effect of necrosed particles of cartilage could be avoided. In other forms of traumatic arthritis also the dislocated cartilage was at fault. It was for these reasons, therefore, that arthroscopy was in place more frequently than formerly, both in case of a dissection process with inclusion of bone, which could be identified by the Röntgen rays, and also in case of a dissection process without bone involvement, which was negative, when the symptoms pointed to mischief in the cartilage. Juvenile arthritis deformans of unknown origin also was a masked traumatic arthritis deformans and as such was amenable to treatment. According to the views of Fr. Barth, Danzig, these cases were the results of traumatic, arthritic, and traumatic-arthritic processes. Hr. Goetjes, Cöhn, pointed out the importance of the crucial ligaments in the origination of free bodies; he had seen three cases in which free bodies formed through rent in the cartilage from violent action of the crucial ligaments. As the cause for this injury was generally very slight, a slight false step perhaps was sufficient to set up after a time symptoms of loose bodies in the joint.

AUSTRIA.
Vienna, June 27th, 1914.
The Friedmann Treatment of Tuberculosis, (Concluded from our last issue.)

Is one patient the inoculation was followed—locally—after an interval of 48 days by the bursting through of the contents of the“living medicine chest.” Two guinea-pigs were in a similar state and communicated the fistulous discharge. On the death of those animals, a large mass of caseated mesenteric glands was found to be in the abdomen of one, and in the central region of the liver a number of softened nodules, each of these nodules occupied space. One of these similar size and consistence was also found in the spleen. On the other hand, the autopsy of the second animal yielded negative results only. Microscopic examination of the contents of the discharge demanshoned the presence of slender rods, which had been identified as slightly alcohol-fast characters. The cultures obtained therefrom grew and flourished luxuriantly at the ordinary temperature of the room, but rather feebly when exposed to the incubator. The cultures displayed a greasy, viscid, mucous character, which distinguished them markedly from the dry, crumbling quality and consistence of the cultures of the tubercle bacilli procured from mammals. After obtaining a pure culture, another pair of experimental inoculations were carried out on a guinea-pig, and the other on a rabbit. After an interval of three weeks both animals had elapsed those animals were killed. The body of the guinea-pig displayed an advanced stage of degeneration of the parenchymatous tissues of the organs, with formation of some nodules in the lungs, liver, spleen; that of the rabbit presented nodules of the size of hempseed scattered about through the liver. The microscopic examination of the organs had not been carried out but only to the effect that no definite statement could be made regarding the presence of tubercle bacilli. The results of investigation have so far, accordingly, gone to prove that the remedy is not so innocuous as Friedmann would have us to believe. That it occasion-ally provokes rather disagreeable formations is shown by the nodular deposits which follow injection into the tissues or blood-vessels of animals, and its inoculation on serous surfaces. The clinical observations which had been made in cases of human tuberculosis went collectively to show that the condition was made worse by the administration of the Friedmann remedy. Intravenous injection was followed by the production of profound mischief in the parenchymatous organs, which had lasted for months, and had even involved the most minute lesions. In this account it is, of course, most desirable that everyone who has for this purpose prepared would be absolutely warned against the danger of its use.

Dr. W. Budinger described four cases—two of tuberculous fistulae, one of cold abscess originating from the spongy, synovial surface of the symphysis, and one case of tuberculous lymphoma of the neck. The first three had been considered by Friedmann but little suitable for the administration of his remedy, but he regarded the lymphoma as a most desirable case for testing its therapeutics. In the case of a 5 years old child, in which origin of the neck was observed to increase considerably in size after the injection had been used, and the general condition of the patient, who had suffered from proloned fever after the administration, has ever since grown worse.

Dr. O. Földner described the cases of five patients with variously localized foci of tuberculous disease, all of which had been injected by Friedmann himself. One of those had been cases of oesophageal tuberculosis with co-existing fistula; one was a case of cold abscess which had originated at a focus of costal caries, and the fifth case was one of renal tuberculous. The ages of the patients who suffered from oesophageal tuberculosis were associated. One was 6 to 10 years old; the other two, one was 36 years old and the other 40. One of the five cases had an intravenous injection administered, and this was followed by intense reaction, accompanied with high fever, rapid pulse, vomiting and diarrhoea. In the cases of the other patients who remained under treatment and observation at the institution for a period of three months, not one presented any other improvement beyond what had been previously experienced by other cases under the other varieties of counter-therapeutical treatment. In not a single instance did any striking improvement occur which could be attributed to the specific influence of the remedy employed. At present date—that is to say, after the lapse of an interval of five months—the operation in the case of oesophageal tuberculosis with discharging fistulae had had no notice therapeutic effect. The purpose of ascertaining whether any reaction would be manifested in the co-existing tuberculous lymphatic glands of the neck, these were eripated after an interval of three months had elapsed after the date of the injection. In the case of ren tuberculosis, in which nephropathy had been carried out five weeks previously on account of peritrophritic tissue thickening and transitory insufficiency of the other kidney, the infiltrate had been reabsorbed
CORRESPONDENCE.

Dr. Thaddaus Majewski reports that during the past few months 49 syphilitic patients were treated in the dermatological section of the K.K. Garrison Hospital, Lemberg, according to the regime of the merlusin cure. Of that number, 17 had undergone previous treatment. The other 32 were cured of recurrence of the disease after previous treatment. In carrying out the merlusin therapeutics, pastilles of this remedy were administered three times daily, always after meals. All acid foods were rigidly excluded. The preparative regime was maintained during a period of from four to six weeks. During this interval many of the patients increased notably in body-weight. Symptoms of intoxication or other specially unfavorable manifestations were never observed. In some of the cases the previous curricular courses ofunction and injection had produced ulceration and detachment of the tissues of the gums and aggravated examples of mercurial stomatitis, to such extent as to demand immediate cessation of treatment. Every one of those was found to tolerate the merlusin cure without the least inconvenience. The external manifestations of syphilis (initial sciereses, indolent bunoes, nucous and cutaneous patches, condylomata lata, laryngitis, etc.), were submitted simultaneously to appropriate local treatment.

As in the case of every other anti-lictic remedy that has hitherto been tried, the adoption of the merlusin cure has not—on account of the very various degrees of lesion—always been accompanied by correspondingly satisfactory results in all cases. But the external syphilitic lesions attained to complete healing in every one of the cases submitted to the merlusin cure, and secured this result more rapidly and satisfactorily without the use of any other external or internal treatment.

The result of the Wassermann reaction from positive to negative was always established, either immediately after the completion of the cure, or after a short interval had elapsed.

A record so strikingly successful testifies to the possession of energetic curative properties by this new remedy. Besides, a specially favourable item of testimony is afforded by the fact that in the various degrees of success which it has hitherto obtained, and of permanency of results secured, have proved immeasurably superior to those achieved by any of the long list of other mercurial preparations that have hitherto been employed. Thus the claim has been definitely established that in merlusin we have found a remedy which is at the same time energetic, perfectly innocuous and without any disagreeable properties or after-effects.

HUNGARY.

Budapest, June 27th, 1914.

THE ACTION OF MOUNTAIN CLIMATE ON EXUDATIVE DIATHESIS.

Dr. Dalmary practises at Ta'trafured (height about that of St. Moritz in Switzerland), and he states that the climate there has a remarkable action on the Exudative Diathesis, and especially on one of its principal manifestations, bronchial asthma. The general health improves, the blood-picture shows marked benefit, and the nervous system gains tone. It is a familiar fact, he says, that the constitutional diseases are much rarer among the inhabitants of mountain districts than elsewhere, and when they occur they are of a milder type. Of forty 11 patients with bronchial asthma, brought up into the mountains as the last resort after failure of all other measures, had no further attacks. Only two of them had a mild recurrence in the first two weeks after an intercurrent severe cold. But on return to the lowlands, all asthma recurred within 6 days and yielded so readily during a second sojourn in the mountains. His experience confirms the necessity for making the most of the first stay, lengthening it out to a year if possible. The task is to transform the exudative diathesis of bronchial asthma, as this cannot be done in two or three weeks. It requires a year at least. Further treatments should be made for outgrowing the tendency in children. Eight of his forty asthma children had obliterative eczema, and four of these frequently had fleeting urticaria. All were extremely nervous children; three had convulsions and spasms—all that confirms the assumption of the under-lying diathesis.

TRAIAna in the etiology of cancer.

Andriska reviews ten cases in which cancer developed at the point of a trauma, and a claim was made for industrial insurance money. In only a few of the cases was a causal connection probable. In one case the trauma was a fracture of the femur at a point which proved to be already the site of a sarcoma, and the limb was exarticulated—the trauma in this case revealed the malignant disease long before it would otherwise have been detected. In the case of a man of 74 who fell against the lumbar region a sarcoma gradually developed in the right kidney, and the kidney was removed the fourth month, but the patient succumbed to metastasis nine months after the accident. An insurance claim was made, but the death was being regarded as the result of the injury, but this was accepted in only one of the other cases.

ON ACUTE AND CHRONIC INTESTINAL CATARRH IN CHILDREN.

Dr. Aufricht remarks that the diarrhoeas of children are the daily bread of the general practitioner, and declares that the practical wisdom of children to "flour-soup" (brown flour with butter and water to make a soup) after a day of restriction to tea alone, is what often transforms a harmless acute enteritis into a chronic catarrh. He is convinced that excessive carbohydrate fermentation is the primary cause of severe dyspeptic disturbances, both in infants and older children. The physiologically weak intestine of the infant and the intestine of the older child, after it has been weakened by severe disease, behave alike in respect of carbohydrates. Boyau says that at all ages starch, bread, milk, and all carbohydrates entail most readily intestinal catarrh, as the starch waste in the bowel putrefies so easily. Aufricht also strikes milk from the diet in the diarrhoeas of children for at least a week after the stools are normal once more. The albuminous type of food with fat, but very little carbohydrates, should be the main reliance. The food should all be put through a hair sieve for infants, through an ordinary sieve for children. He allows by the second day two tablespoonfuls of white cheese with a slice of white bread, mixed with a little warm saccharin water and put through a sieve; the third day bouillon with one or two tablespoonfuls of boiled or raw meat, all sieved. By the fourth day he permits addition of two tablespoonfuls of spinach or turnip, with a banana. The above is the diet for a child of four or five; it represents about 1,204 calories, which is not much below the normal ration of 1,380 calories for a child of this age, but the proportion of carbohydrates is scarcely a tenth of that in the ordinary ration. In his extensive experience this albuminous type of diet has proved its usefulness in acute cases and is far superior to the "flour-soup" diet in the subacute and chronic cases. He has never known it to fail to date.

Mr. Francis Vacher, F.R.C.S., M.R.C.P., of 5, Carns Road, Birkenhead, Cheshire, late Medical Officer of Health for Cheshire, left estate of the gross value of £39,839.
CONTINENTAL HEALTH RESORTS.

SWITZERLAND.

The Queen Alexandra Sanatorium at Davos Platz.
The Queen Alexandra Sanatorium at Davos Platz, Switzerland, is situated 4000ft. above the town, and gets at that elevation a maximum of sunshine. The attractions of Davos and the unique value of the climate are sufficiently appreciated in England. Situated as it is in a beautiful mountain valley 5000ft. above sea level, it offers to the invalid suffering from pulmonary disease, a dry, breathing climate with the purest of pure air. The valley enjoys a temperate, still atmosphere, particularly in winter, being almost completely sheltered from wind; and the long hours of sunshine render the cure attractive and pleasant both in summer and winter, so much of the invalid's time being spent in the open air. It is not generally known that the climate of Davos affords not only a winter cure for consumption, but a summer alpine cure as well; whilst the summer heat is never oppressive.
The Queen Alexandra Sanatorium is a self-supporting benevolent institution, built by public subscription for the benefit of English-speaking subjects. The fees are extremely moderate, being only £2 25s. weekly, and include board, residence and medical attendance. Every patient has a private room with balcony facing south. To those who wish to combine this cure with an altitude cure with modern sanitary improvements and under English management, this Sanatorium is strongly recommended.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH.

The Chairman of the Scottish Insurance Commissioners (who was knighted the other day) addressed the Scottish National Conference of Friendly Societies at Stirling on June 20th, on the possibilities of the Insurance Act in the future. He said that contributions had been very fully paid, and that there had been little or no evasion; the Scottish Fund at present was over five million pounds, and he hoped that they had paid in nearly £2 million pounds, leaving for investment a reserve of £1 million. Nearly £12,000 a week was paid out in sickness benefit, £3,000 in maternity benefit, and £12,000 in medical care. He discounted all stories of the impending bankruptcy of some societies; societies which only took selected lives were over-insured and would have surpluses; those which did not take such good lives were under-insured, and probably would have deficits. All this, however, was provided for in the Act, one of the most valuable provisions of which was that ensuring the solvency of the societies. Levies were unpopular, but all that would happen was that the societies which had a deficit would not be able to pay as much instead of 10s. per week until their affairs righted. That was not bankruptcy, but merely temporary adjustment. As regards women, no purely Scottish women's society had an adverse experience, although it was admitted that the new laws had brought harm. All the same sickness in women, and the figures pointed generally to the health of women, especially married women, not being so good as that of men. There was a case for examining whether the contributions paid by women were high enough. From the point of view of the approved societies he questioned whether many of the claims relating to pregnancy which had been paid ought to have been paid at all. If, however, it was urged that the health of the women was the nation's care, he would be loath to make suitable provision. He thought that complaints against the societies for non-payment were quite groundless; most on the other hand had paid out money, if anything, too freely. The complaints as regards doctors had not been numerous so as far as actual attendance was concerned, but there had been many vague complaints of laxity in certification. This applied only to a minority of doctors, and there had been the greatest difficulty in getting the societies to substantiate the complaints. The present attitude of the Commissioners was that they were meeting the doctors in every way, explaining the position, urging co-operation in securing efficient administration. He thought they were getting this through the doctors themselves, through the panel committees, and through the General Medical Council. The opposite proposal that it be distributed in proportion to the length of the doctors' lists was also rejected. The final decision was to divide equally—carried by 29 votes to 11.

CLINICAL TEACHING IN EDINBURGH.

Arrangements have now been made which will have the effect of systematising the clinical instruction given in Edinburgh. The scheme is rather complicated, but its general principle is to divide the students in their last year into three sections, and to send each section in turn for one week to a particular hospital, and to prevent overcrowding in any one term. In former years, when the special subjects were to a certain extent optional—e.g., when a man might take either diseases of children, ear and throat diseases, or dermatology, the whole number who attended these classes to be taken in the summer, the result being that they were unduly crowded, especially that on diseases of children. Now that they have been made compulsory, some method is necessary whereby the whole resources of each department should be utilised throughout three terms, instead of being partially neglected in one or two terms. As matters now stand, Section A, for example, will be compelled to attend ear and throat diseases from October to December, diseases of children from January to March, and dermatology from May to July. Another advantage is that on the new plan each section will have more time than hitherto for each subject, which is especially important in connection with diseases of children, for the time allotted to this subject has in the past proved quite inadequate. The way in which the new scheme has been worked out reflects the greatest credit on all concerned, and particular thanks are due to the Dean of the Faculty, Professor Harvey Littlejohn, for the wholehearted way in which he has thrown himself into the work of resolving conflicting interests and producing a harmonious scheme.

GLASGOW.

Sanatorium Treatment Cut Short.
As a result of a deficiency of funds, the patients in the sanatoria of Ayr Burgh Insurance Committee are to be brought home, although the letter which the Clerk, in reply to one sent by the Clerk, stated that the Commissioners would not be prepared to advance more than the proportion of funds applicable to each quarterly period, and suggested the exercise of exercising caution in extending the amount of sanatorium benefit. At a meeting of the Committee, the Clerk stated that if they went on spending as they were doing at present, his estimate would be exceeded by about £900 at the end of the quarter. Mr. Corrigan moved the approval of the sub-committee's recommendation that the patients should be brought home. He knew that the proposal on the face of it looked

THE GENERAL MEDICAL COUNCIL AND "THE FAMILY ENCYCLOPEDIA."

To the Editor of THE MEDICAL PRESS and CIRCULAR.

Sir,—I am your obedient servant, on this subject in the MEDICAL PRESS and CIRCULAR for June 24th, page 624, you say, and quite truly, that the advertisement of the names and professional titles of a number of medical men with a popular medical work constituted an outrage upon the established methods and traditions of the medical profession. You did not, however, attach any blame more serious than that of "inadver tence" to Sir Clifford Allbutt, and inferentially to the other inadvertisers. In this respect you stand condemned as guilty of neglect of duty. As I am one of those, I trust you will allow me a few lines to say that even the blame of "inadvertence" can hardly be attributed to me. The only inadvertence of which I have been guilty, if inadvertence it can be called, was that of giving to a young man who had studied at St. Bartholomew's Hospital the assistance which he wished, without ever dreaming that he would misquote my name, and without therefore calling upon him beforehand for a guarantee that he would not do anything out of which I might be supposed to have been offended. The statement that the men whose names were advertised in connection with the "Ency clopedia" revised the proofs of that work is certainly untrue in regard to myself, and to some others whom I have asked to look into the matter with regard to that advertisement. Riddle told me that he was writing a book, and that one section of this was on alcoholism. He asked me to look over his article and see that he had made no mistakes, as he was anxious that anything he published should be correct and that it should do no harm. I answered his request, and looked over his typewritten copy. I thought no more of the subject until I saw my name advertised along with a number of others in the Daily Mail of February 26th. A few hours after my attention was directed to this, I received a telegram from Dr. Riddle to this effect:—"Have been ill past week. Amazed at gross advertising of names in connection with my book. Have wired publishers to cease immediately. Please accept this apology."

This letter was followed on March 3rd by the following letter:—

"Dear Sir Lauder Brunt—, I trust that you will believe that I am as much upset as you yourself must be at the manner in which in my absence (ill for 3 days) your name has been advertised in connection with my 'Family Encyclopedia of Medicine.' I have written the following letter to the Lancet and British Medical Journal, which I trust will, at any rate, show your own complete ignorance of the manner in which your name was to be blazoned abroad:—

To the Editors of the Lancet and British Medical Journal.

Dear Sir,—I wish to express my regret that the publishers of my "Family Encyclopedia of Medicine," in an excess of zeal to make all due acknowledgement of the assistance a large number of my friends and acquaintances in the profession have given me in the way of correcting and revising special articles in the book, have advertised their names in a manner most contrary to the ethics of the profession. It is necessarily severe for me to say that both my medical and nonmedical friends who have been thus advertised were quite unaware that their names were to be advertised in this fashion. I have also taken steps to prevent that in the future when drawing up advertisements for the "Family Encyclopedia of Medicine," the publishers will have due regard for the ethics of the medical profession.

Yours faithfully.

[Signature]

Hugh A. RIDDLE.

The President and Censors of the College of Physicians and the Central Ethical Committee of the British Medical Association demanded an explanation of the appearance of my name in the advertisements. I forwarded them the letter and telegram which I received from Dr. Riddle, and the letter and telegram which Dr. Riddle received from me.
have quoted above in order to show that the advertise-
ments were entirely without my knowledge or consent. These bodies accepted the engagement; and I trust, Sir, that you and your readers will regard them as sufficient to free me from any blame—even that of "inadvertence."

I am, Sir, yours truly,

LAUDER BRUNTON.

London.
June 26th, 1914.

THE "FAMILY ENCYCLOPEDIA OF MEDICINE."

To the Editor of The Medical Press and Circular.

SIR,—In to-day's issue of your journal under the heading "The General Medical Council and the Family Encyclopaedia," you suggest that the Council abstained from taking action against the contributors to the Encyclopaedia because one of its members happened to be in that position, while you further say that the Council "brought the full weight of its ponderous displeasure upon an unhappy panel practitioner whose renegade society's officer lacks the slightest basis of foundation in fact and should be withdrawn. I do not wish to mention the names again, but I will refer to the cases in the order in which they were brought before the Council by the British Medical Association, and the Council would have laid itself open to a serious complaint had it refused to allow the questions involved to be duly enquired into, but not one of the cases affords the slightest foundation for your statement that the Council brought the full weight of its "ponderous displeasure" upon any one of the persons brought before it.

I am, Sir, yours truly,

ROBERT SAUNDBY.

Birmingham.
June 24th, 1914.

The paragraph referred to by Dr. Saundby expressly denied any possibility of the kind as regards Sir Clifford Allbutt. The high character of that gentleman is too well known to admit of any such misinterpre-
tation. If our paragraph be taken to indicate any such belief, we take this opportunity of expressing in the strongest way our regret that it may have been open to any such construction. At the same time Dr. Saundby, in a "Popular Encyclopaedia of Medicine" of the names, titles and professional appointments of a number of medical men constitutes an astounding reversal of medical tradition. That being so, the more illusory, the same necessity is the rehabilitation in the eyes of the profession generally. That can be done either by legal process or by express and explicit letters to the medical journals. As to the other point mentioned by Dr. Saundby, a reference to our original paragraph will show that the word used is the "displeasure" of the Council. We fancy that Dr. Saundby's letter supplies abundant proof of his interpretation. After several months and public apologies are surely sufficient; and if the displeasure, apart from the mere fact of costs of proceedings and mental distress caused by summons before the Council. The British Medical Association, which was responsible for the second presence on that occasion, has issued a strong declaration on the subject of dealing with professional subjects in lay publications—but that is another matter.—ED. M.P. and C.]

OPEN SPACES AND PUBLIC POLICY.

To the Editor of The Medical Press and Circular.

SIR,—My card enclosed will show you that I bear a well-known medical name. My interest in your profession and science is thus accounted for. It leads me to read every week one or other of the medical journals that I find on my club table. To-day I have lighted on your issue of June 24th containing the letter by Dr. Fletcher Little under the above heading. The main fact of the situation does not seem to be recognised by Dr. Fletcher Little. This fact is that the overwhelming mass of the present generation of Britons are absolutely devoid of the smallest modicum of feeling for natural beauty and for art, Members of Parliament, including both Houses, merely sample the general public. If they gave any thought worth mentioning to the welfare of the nation, they would play a larger part in the preservation of our heritage. Our public parks are examples of brutal philistinism of which Dr. Fletcher Little gives only one example out of thousands would be impossible. Dr. Fletcher Little and his friends will discover the inability of the present public, a large proportion of London Members to act with vigour born of personal feeling in the question of Regent's Park, and in arousing even a languid feeling in any part of the House. I believe that the artistic sense has been driven out of public thinking. In a recent century of industrial development the intellect of the people has been almost completely absorbed in the wielding and directing of new mechanical power—steam and electricity—and in gathering the wealth it has produced. Has any local public authority throughout the land constantly offers illustrations of these facts; and the same phenomena are observable in what ought to be our most enlightened bodies of the Metropolis, and in the Government itself. The destruction in Regent's Park of the beautiful buildings and monuments of a great age, a score to be followed by more scores of similar incidents during the development of the national estate of which the Park forms a portion. From Trafalgar Square by Pall Mall, through Waterloo Place and Regent Street to the end of Regent's Park, the beauty of the buildings are now falling, together with Regent's Park, into the hands of the Government. The estate might have been made into a line of thoroughfares superior in architectural beauty to anything in Paris or in Western Europe. The buildings are being allowed of a height detrimental to architectural beauty, and which must prove injurious to health in excluding sunshine and impeding the movement of air. The architects are being given a free hand to carry out their own designs, as if, in the opinion of the Council, the public would be better served. It is, of course, all done by the steel framework within; but it forms the negation of beauty. No people with any feeling for beauty could allow for one day in the very centre of the capital of the Empire the existence of that queer jumble of uninteresting caricatures of architecture and art formed by Trafalgar Square; nor could they have allowed the pitiable modelled made at the entrance to the Mall—a muddle contributed to by two of the chief municipal architects, as well as to the Government itself. London, with its misty atmosphere, which veils so much ugliness, is developing magnificent vistas.
but it is all accidental and not with design or any sacrifice to art. On the other hand, Paris, although open to much criticism, is beautiful because her people will to have it so. As a straw is enough to show the way of the wind, one characteristic of the nation may be enough to show the direction in which it is really marching. A great part of national effort during the past century has represented hurtful movement merely, not true progress, albeit constantly misinterpreted for it. The question is, can people be gradually moving to a higher plane of civilization when devoid of the ideals that express themselves in the cult and care of beauty in nature and art—this question is surely worth the study of the physician and of all men who, to them, are vitally compelled to be students of sociology in general and of the evolution of our modern society in particular.

I am, Sir, yours truly,

AN ARCHITECT.

REVIEWS.

HELIOTHERAPY TREATMENT.

To the Editor of The Medical Press and Circular.

Sir,—I have been using the sun rays in the treatment of disease for twenty years, especially tuberculous disease, and have employed them in hundreds, if not thousands, of cases referred to in your issue for June 17th, stated that "the cure of tuberculous disease by sunlight is a new science. Of course, English physicians have not the advertisement drum to advertise it. Only a majority treatment like our Continental colleagues and we have not the Alpine altitude, rarefied air and abundance of winter sun, but we have many places where the curative effect of sunlight can be carried out without going to the Alps for it. It cannot be a very new treatment when I have advocated it for such a long period, and I must confess my attention was called to it by reading an account of such treatment by the Romans. I therefore first applied it in some cases of old chronic indolent ulcers and afterwards to tuberculous disease. I reported a very satisfactory case of tuberculous laryngitis recently in a contemporary, where daily exposure of the throat to sunlight formed part of the cure. Of recent years I have employed magnifying glasses to concentrate the rays on a definite spot, and at the present time the Surgical Manufacturing Co. are devising me an instrument to hold the different size glasses, in various positions, so that the cure can be carried on by the patient, or by the nurse or attendant. I hope to submit it for your expert opinion later on.

I am, Sir, yours truly,

THOMAS DUTTON, M.D.

London.

June 26th, 1914.

OBITUARY.

DR. F. T. PORTER NEWELL, DUBLIN.

We announce with much regret the death of Dr. Frank Thorpe Porter Newell, F.R.C.S.I., of Dublin, who died last Wednesday after a tedious illness, at the age of 53. Newell was a graduate in arts and medicine of Trinity College, Dublin, since 1881, and a Fellow of the Royal College of Surgeons in Ireland since 1882. For the past few years he had been a member of the Council of the College. In his young days he was apprenticed to the late Sir George Porter, and was a student of the Meath Hospital. He was subsequently House Surgeon of the Meath Hospital for no less than seven years. On leaving the Hospital he was appointed Dispensary Medical Officer of one of the Poor-law districts of the city, and he held that position up to his death. During the past three years he took an active interest in the questions that have arisen for the profession under the National Insurance Act, and he was one of the most energetic members of the local Medical Committee of the county borough of Dublin. He was also a member of the Irish Medical Committee. As a member of the Council of the Royal College of Surgeons he kept that body closely in touch with the problems that affect the general practitioner, and the loss of his influence in this way will be felt. Dr. Newell was personally somewhat reserved in manner, but to those who knew him he was the most loyal and trustworthy of friends. The energy and business ability which he brought to bear on the work of the profession in regard to the Insurance Act were something of a surprise to those who did not know him well.

Some months ago he developed a tumour in the neck. Operation gave only temporary relief, and for the past two months he bore his illness with exemplary courage and patience.

DR. J. A. KEAY, OF GREENWICH.

We regret to record the death of Dr. Joseph Hay Keay, who took place on June 17th, at 126 Greenwich Road, S.E. A wise counsellor and a skilful medical practitioner, he will be greatly missed by a great many in Greenwich, which is the poorer by his decease.

Born at Forthom, near Blairgowrie, Perthshire, on November 15th, 1849, the son of Mr. John Keay, farmer, of Over-Forneth. He was educated at Blairgowrie, Perth Academy and Edinburgh University, at which latter seat of learning he graduated M.A. at the age of 18 years, and won many prizes and medals, and was universally esteemed by his fellow students of theology for four years, and became a licentiate of the United Presbyterian Church of Scotland, but turned to medicine and took his M.B.C.M. in 1867 and his M.D. in 1862.

Keay practised first in Crook, Durham, where he married Annie Laura, the eldest daughter of Mr. L. Candler, of East Lodge, Crook. He then proceeded to Blairgowrie, where he practised for seven years. As a member of the School Board, he took much interest in questions of local education. After practising in Colne, Lancashire, for ten years, he came to Greenwich in 1899, where his work on the Greenwich Board of Guardians, and, later, State insurance, took up much of his time. He never spared himself in any of the various fields in which he took an interest. He was an active member of the British Medical Association and frequently represented the Greenwich division at the annual representative meetings. He was a keen student of the various kinds of light of St. Ray's insurance against sickness in operation on the Continent, and took an active part in endeavouring to ally professional anxiety in connection with the introduction of insurance. As the first Chairman of the Western Hospital, he represented the insurance practitioners in London, a post which he was compelled to relinquish owing to his failing strength, and the breakdown in his health was no doubt largely due to his unselfish devotion to the public interest. He bore his long and very painful illness with the fortitude and patience which those who knew him would have expected. All his life he was a loyal and zealous member of the Presbyterian Church, and for several years past he was an elder of St. Mark's Presbyterian Church, Greenwich. He leaves a widow, a son and two daughters. In 1902 Dr. Keay published "The Medical Treatment of Gall-stones," and he was also the author of many pamphlets and articles.

REVIEWS OF BOOKS.

HYPNOTISM AND SUGGESTION. (a)

Much progress has been made in the study of psychotherapy during the six years which have elapsed since the last edition of Dr. Lloyd Tuckey's "Hypnotism and Suggestion." (a) That it has attained the position of a classic in the branch of medicine with

(a) "Treatment by Hypnotism and Suggestion, or Psychotherapeutics," by C. Lloyd Tuckey, M.D., M.A., Member of the Medical Faculty of the University of St. Andrews, Etc., Etc., M.D., D.L., K.S.G., Ordinary Physician to the King in Ireland; Theories of Psychotherapy and J. Roget, M.D., Ph.D., Theories of Psychoanalysis, by Dr. C. L. T. Done, S. A. C. P., pp. 288, 481, London: Bailliere, Tindall and Cox, 1913. Price 10s. 6d. net.

"Treatment by Hypnotism and Suggestion, or Psychotherapeutics," by C. Lloyd Tuckey, M.D., M.A., Member of the Medical Faculty of the University of St. Andrews, Etc., Etc., M.D., D.L., K.S.G., Ordinary Physician to the King in Ireland; Theories of Psychotherapy and J. Roget, M.D., Ph.D., Theories of Psychoanalysis, by Dr. C. L. T. Done, S. A. C. P., pp. 288, 481, London: Bailliere, Tindall and Cox, 1913. Price 10s. 6d. net.
which it deals is acknowledged by those who recognise the value of suggestion as a form of treatment. The influence of the mind over the body is so great and so far-reaching that no practitioner who wishes to establish his reputation in general practice can afford to neglect the study of mental methods and their application to the treatment of functional nervous disorders. In view of the recent report of the Committee upon "Spiritual and Mental Healing," it is somewhat surprising to find that no evidence was given there to the effect that spirituality can add a curative touch to physical treatment. Dr. Tuckey believes that instruction in hypnotism and practice should be given in general hospitals and medical schools as a part of the student's curriculum. It is certain that if the medical profession does not recognise the utility of suggestive methods in suitable cases, the door will be thrown widely open to quackery, for hypnotism affords special scope to charlatanism. A succinct account of Freud's method of psycho-analysis is contributed by Dr. Constance Long, who points out its superiority for enabling us to understand the workings of the human mind. It is when the psycho-neurotic approach of his phobias, obsessions, and hysterical symptoms, that they will disappear. We have every confidence in recommending this work to general practitioners and others interested in the study of psycho-therapy, for in its pages will be found the latest information respecting this engrossing subject.

ANESTHETICS. (a)
It is now almost exactly seven years (July, 1907) since we reviewed in the pages of this journal the fourth edition of Dr. Buxton's book, and it gives us great pleasure to welcome a new edition, with a cordial welcome to that which we gave to the last. The past seven years have been full of fruitful activity in the field of research as regards surgical anaesthesia, and Dr. Buxton gives us on the whole an admirable summary of the results that have been obtained. New methods are described and their value appraised by one, who, though he long used the older methods with a master hand, has not shirked the responsibility of taking the ground of experience. How far the new methods will displacce those formerly in use is as yet impossible to say, but we feel confident that much that is new in anaesthesia has come to stay, and to stay too for the advantage of both patient and operator. We believe, no text-book in the English language that will give the student and practitioner a better knowledge of these new methods, their limitations, and their uses, than Dr. Buxton's book now before us.

EXPLANATORY LECTURES FOR NURSES. (b)
It is quite refreshing to come across a modern work written for nurses that is not too advanced, for although this little book includes teachers as well as nurses, the style is simple and practical. The author believes in the free use of homely comparisons when lecturing to nurses, even though, as everyone who has so lectured knows, there may be a risk of homogeneity. We have endeavoured, in the chapter on the blood, intended for young women of the working-class, we find the following:—"The blood is the carrier of the body. The carrying is rather a continuous one. The blood is set in motion by the heart. The blood is supplied and service and vestry, ask-cart service in what worked to gratify the tastes of the principal agent, Mr. Hemo-globin and for the good of the neighbourhood it serves. It should be said, however, that the greater portion of the blood goes on with a wider range of subjects, contains much practical information, delivered in the lecture-room, which will be found helpful by nurses or by those who have to conduct classes for nurses. An index would have added greatly to the efficiency of this useful little work.

ELECTRO-PATHOLOGY AND THERAPEUTICS. (c)
We are always hearing or reading the statement that over-specialisation is one of the characteristic evils—perhaps the greatest evil—of our present generation, as well as not wholly unimined with good—of this over-worked and over-educated and over-worried generation. We believe the statement so expressed to be nearer representative truth than most of those to which we are accustomed to be treated regarding the present as compared with the past. But if British twentieth-century civilisation presents on one side a specialised aspect, it displays an encyclopedic one on the other—originally prepared and illuminated by the possession of such a book as a universal reference as the "Bibliotheca Britannica," and subsequently nourished by the daily bread of the "penny" newspaper. And this existing arrangement furnishes an opportunity for the development—indeed, is practically implies the existence—of connecting links or rods, of pronounced individuality and power of resistance, which unite the opposed and parallel strata. Such individual bonds and bars have their position a good deal favoured by the inevitable and permanent separation of the latter, which gives the intermediates the opportunity of working simultaneously upon the pabulum supplied by both neighbouring structures. The case before us seems to illustrate and exemplify the point of view which we endeavoured to present. The joint authors of the present work are lay scientific specialists at one extreme aspect of their auto-presentation and medical experts at the other. The wide—and still somewhat weird—domain of electricity leaves even now the most ignorant, and yet the imagination of "the general," and the unsatisfactory results of "anti"-campaigns against some of the most familiar and most deadly diseases furnish a temptingly wide scope for the culture of opportunism—to use a somewhat artistic phrase.

It is useless to attempt to examine in detail the claims here advanced. We can only refer to a specimen brick or two, from which the skilled reader may perhaps be able to form an opinion regarding the stability of the case. For example, we are told that the temperature of double pneumonia where the temperature has been 105.6° and 106° F., and show that in every case the temperature fell to 100° within an hour of the electric treatment being applied, and that rapid recovery followed. Corresponding patients have been treated with the result in the treatment of acute appendicitis. Then with regard to the permanent white scourge we are told that: "Specific remedies innumerable have been tried, but of these 'tuberculin' alone retains some semblance of vitality." Not so with the present neuro-electric, under the influence of which "the bacilli are almost at once rendered inert and . . . . thereafter give no trouble which is not in the power of the ordinary medical practitioner to cope with." We trust that we have now helped the reader towards the formation of an opinion, and must here leave him to acquaint himself with the balance of the text of this interesting, well-printed and well-illustrated volume.

A Motor-Car Manufacturer's Munificence
It is announced that Mr. Henry Ford, the motor-car manufacturer, who two weeks ago gave £600,000 to General Hospital, intends to convert the hospital into an institution for the study and prevention of tuberculosis and cancer.

The Newer Conceptions of Syphilis and Parturition.—Lobensteiner (Am. Jit. Obs., lxix., 319) states that in considering Colles' law that of 145 mothers who had at no time been treated, nor had presented signs of syphilis, but who gave birth to syphilitic infants, 71 per cent. gave a positive Wassermann reaction after labour. Of 25 mothers with symptoms of syphilis, 21 per cent. gave a positive Wassermann reaction. That a specific parent or parents may give birth to a non-specific child is greatly doubted from the findings with Wassermann's reaction. Those rate cases in which an infant apparently escapes infection are dependent, not upon immunity, but upon the well-known fact that the syphilitic virus shows a natural tendency to lessen in virulence with passing years. Opinions are rather divergent as to the value of the Wassermann reaction in infants, but with proper technique, the results will give the reaction in most cases. The results upon the fetus from treatment of the mother with mercury have been uncertain. Savaran affords greater hopes of success, especially when combined with mercury by injection. The action of the arsenic protects the child until the birth, and then its action becomes large measure. With salvarsan the intra-uterine death-rate is about 15 per cent., while with mercury it is about 65 per cent. per cent., which is usually used regularly throughout the entire period of gestation. All children born of suspected parents, or parents who give a plus Wassermann reaction, should have their blood examined soon after birth, and should have active treatment in the presence of a positive reaction, even when this is the only indication of disease. The treatment should be direct either with arsenic or mercury.

The Present Status of Fibroids of the Uterus.—Schoenberg (Am. Jit. Obs., xix., 3) from an extensive consideration of the results obtained by operations, either myomectomy or hysterectomy, and the numerous complications and degenerations which the old conservative attitude towards the removal of fibroids is no longer justified. The indications for operation are considered to be—malignant change, when situated in the lower uterine segment, obstructing the birth-channels; the size of the tumour to cause pressure symptoms. In the case of young women myomectomy is the operation of choice. It is estimated that only 10 per cent. of the women who have myomectomy performed subsequently bear children, and therefore future child-bearing should not too strongly influence the decision between myomectomy and hysterectomy. The best results are said to be obtained by supravaginal hysterectomy. The reports of Röntgen therapy are considered, and if the results prove to be as favourable as the early reports showed the method would supplant surgery in many cases. However, unfavourable results are steadily being reported, and only a small percentage can be classified as complete cures. The majority of so-called cures are only cessation of symptoms. Another factor against the Röntgen rays is the damage done to the ovaries. It is claimed that the effect is primarily on the ovaries, and where the ovaries are behind a large tumour the rays produce no result. Therefore operation is claimed to be more conservative than by retaining the ovaries and allowing other structures to be treated which may be involved. Statistics are quoted showing that out of 380 cases in which the tumour was indicated only 5.3 per cent. showed disappearance of the tumour.

Ectopic Pregnancy, and Repeated Pregnancies.—Spengler (Springer's Jit. Obs., xixii., 101, from cases collected, found that in 144 women operated upon for ectopic pregnancy and living subsequently in connection with the pregnancy, in which pregnancy was possible, 47, or 32.6 per cent. had uterine pregnancies, and 21 had repeated ectopic pregnancies, or half as many as had living children. Of 67 women under 30 years of age, 27 had uterine pregnancies, and 10 had ectopic; while of 74 above 30 years of age, 19 had uterine pregnancies, and 17 had ectopic. In 3 out 100, or 3 per cent., less than half the patients bear children subsequently, and 14.6 per cent. repeat the ectopic pregnancy. The question is raised whether it is best to save the other tube when it seems capable of transmitting the ovum, and it is considered that which the disease had been upon the state of the tube for future pregnancies, but upon the number of children the patient has borne, her general health, and her desire for future pregnancies.

Milroy's Disease.—Phillips (Cleveland Med. Jit., May, 1914) records two cases of persistent hereditary oedema of the legs, or the so-called Milroy's disease. The first was that of a man, at 40, in whom the condition had been present ever since he was 15 years of age. The condition had never caused him any inconvenience except at times when his legs became red, swollen, hot and tender. These acute exacerbations would pass off in a few days, and for many years the attacks would recur at intervals of about six months. Latterly, however, they had become more frequent. The second case was in a boy, at 6, the son of the first patient. The condition had been present from the time when he was four months old. The diagnosis of the condition is summarised as follows:—The restriction of the oedema entirely to the legs; the absence of any discoverable cause for the oedema, either local or general; the strong family predisposition to the condition; the painlessness of the pale swollen legs, and the absence of any constitutional symptoms; the sharpness of limitation of the upper level of the oedema, and its persistence when once established. The disease attacks both males and females. No treatment seems to have any effect on the condition, except that the swelling may be held in check by bandaging. The disease does not appear to have any influence on the expectation of life of the individual affected.

Paroxysmal Tachycardia in a Child.—Hutchinson and Parkinson (Brit. Jit. Child's Disease, June, 1914) record a well-marked case of tachycardia in a child, aged two years and nine months. This appears to be the earliest age at which the disease has yet been recorded. Between May 27th and October 12th, 1913, the child had in all four attacks. The first attack lasted twelve days, and during it the pulse-rate reached 160 per minute. During the second attack, which occurred four days later, the pulse-rate showed a rate of 215 per minute. The electro-cardiograms showed a similar rate. The fourth attack occurred about a month later, and though a pulse-rate of 225 per minute was recorded there were no symptoms of distress. The last attack ceased suddenly after defaecation.

Tobacco Amblyopia.—Vandergrift (Med. Record, May 20th, 1914) discusses this interesting condition, and records a well-marked case. The patient was a man, at 45, who had never taken alcohol, but admitted to smoking about six cigarettes and one cigar daily for a long thirty years. Vandergrift holds that if the prognosis in the disease is excellent, even in cases of long standing. It may be necessary to persist in
treatment for many weeks before improvement begins, and many months may pass before complete cure is attained, though six to eight is a sufficient time to cure the average case. Not only is the cure almost always possible, but a relapse is almost unknown, even though the patient may continue to use the tobacco in large quantities. Strychnine is considered the best remedy for the disease besides the abstinence from tobacco. The administration of the drug must be begun with the average dose, but as quickly as possible it should be increased to the physiologic limit. It is also necessary to combat the patient's irritability, worry, and any general debility that may be present.

**Medical News in Brief.**

Medical Sickness and Accident Society.

At the last meeting of the Executive Committee of this Society the claim account presented still showed an improvement over that of last year, and the proposals received for these have increased. Outside is a record in the Society's experience. The new combined sickness and endowment table, with reduced premiums for the first five years, is also proving popular with younger members of the profession.

The votes for Epsom College were dealt with at this meeting, there being two candidates for foundation scholarships who are the sons of deceased members. The widow of a late member was also applying for a scholarship which has been awarded to the son of a deceased member. During the past few years the sons of several members have been admitted to Epsom College as foundation scholars, and it is an undoubted advantage to intending applicants to be sure of a number of votes being polled for them by the Society. No extra premium is required to enable members to share in this advantage.

A Difficult School Attendance Case.

At Clerkenwell Police-court last week, before Mr. D'Eyncourt, a child of six was produced whose "name was unprotected," according to a medical certificate which resulted in the loss of a hole in the head, it was reported, "three inches long and half-an-inch wide, and it is hoped that in time a silver plate can be inserted in place of the lost bone. Meanwhile the child has to wear a shield." In the case of a friendly one. The mother thought the child safer at school than in the streets, and the schoolmistress shied at the responsibility of having the child in the school, where the slightest high play might result in serious injury to the child. The magistrate said he saw and appreciated the difficulty, and suggested a "special school." It was explained that the child was not a "cripple," or "physically defective," as constituted by the Act, and could not be admitted until aged seven. In the end an order was formally made for the child at a certain school, to bring pressure to the teacher to admit the child, and presumably give it some individual attention.

Tuberculosis Dispensary for co. Dublin.

A TROPHAL central tuberculosis dispensary for co. Dublin was opened in the grounds of the Meath Hospital last week by Dr. P. J. O'Neill, J.P., Chairman of the Dublin County Council, who referred to the importance of the treatment in rendering a number of persons fit to resume their employment. The present building was a temporary one, pending the opening of the permanent building now in course of erection, and they had also arranged for the use of two small wards in the Meath Hospital. He urged the need of good housing accommodation.

Dr. Coey Biggar, on behalf of the L.G.B., commended the work, and Mr. K. Nolan, in a return showing the number of cases dealt with from the appoint-

NOTICES TO CORRESPONDENTS.

the Medical Journal (July 1912) up to the end of the last completed Insurance Act period (January 11th, 1913) were discharged fit for work, 60 were improved, 41 were not improved, 6 were worse, 34 were discharged for breach of rules or had left, and 28 had died. In the cases of 77 persons discharged fit for work, in 43 cases the improvement was maintained, 17 returned for treatment, and three died.

The Work of Epsom College.

The annual general meeting of the Governors of Epsom College was held last week, when the treasurer, Sir Henry Morris, presented. It is supported by Sir John Broadbent, Sir W. S. Church, Sir T. B. Crosby, Sir Dyce Duckworth, Sir James Reid, and other governors. Among the honours announced were three certificates for scholarships at London hospitals and exhibitions at Oxford and Cambridge. 18 had passed the whole or a part of the first examination for medical degrees of the University of London: 13 had passed the matriculation examination, three of the first class; nine had gained the higher certificate of the Oxford and Cambridge Schools Examination Board; 18 had obtained school certifices; and 10 had gained lower certificates, with 25 first classes.

The National Medical Union.

Mr. W. T. Greenger, of Brighton, presided at a dinner of the National Medical Union held at the Café Monico on Saturday last. Dr. J. Playfair, of Edinburgh, in proposing the National Medical Union,' said there would show that a union of non-panel men was a necessity for the future and to uphold the best traditions of the profession. Speeches were also made by Drs. F. Porter, Brassey, Brierley, and F. J. Smith.

The Alexandra Day Collection in London.

It was announced by the Lord Mayor that the amount of money collected in London on Alexandra Day was over 2,000.

University of Oxford.

In a Congregation held on June 28th, the following degree was conferred:—D.M., G. H. Hunt, Christ Church.

Society of Apothecaries of London.

The diploma of the society, entitling them to practice medicine, surgery, and midwifery, has been granted to Messrs. C. and W. C.

Apothecaries' Hall of Ireland.

The following gentlemen having passed the necessary examination have been admitted licentiates of the Apothecaries' Hall of Ireland: Michael R. Cleary, F.R.C.S.I., L.R.C.P.I.; Peter O'Dwyer, L.R.C.P. and S.I.

NOTICES TO CORRESPONDENTS, &c.

For Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature &c, to avoid the practice of signing themselves "Reader," "Subscriber," &c. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 2½; post free at home or abroad. Postage subscriptions must be paid in advance. For India, Messrs. Thacker, S. & Co., and Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12.12. In Canada, Messrs. Dawson and sons are our special agents for Canada. For contributions are kindly requested to send their communications, if resident in Ireland, to the Editor at the London office, 6, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time, to the name, title, and address of the subscriber. Subscriptions the same rule applies as to office; these should be addressed to the Publisher.
ADVISOEMENTS

For One Insertion—Half Page, Half Page, £2 10s.;
Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 10 insertions at £2 9s. 6d.; 42 insertions at £1, and pro rata for smaller spaces.

Small Articles as for Tracts, Assurances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

TOOTING RESIDENT.—Some: come to welcome the class of advertisement disclosed in the marked newspaper sheet; on others it held their breaths, the exigencies of press-men. In the special case referred to it would seem to be an accidental oversight, for which it would be unjust to hold Dr. —— responsible.

PRIVATE PATIENTS AND THE INSURANCE ACT.

A correspondent asks for information as to whether dispensing for private patients by general practitioners has diminished since the passing of the National Insurance Act. In reply we would say that there is not much reliable information to the subject, but many practitioners do dispense their own medicines in England, except, of course, for panel patients. In Ireland, on the contrary, it is said that there is no objection to dispensing for a patient by his own medicine, in the case of private patients, and to a lesser extent than a bill. Dr. A. S. (Keart)—The electrical sterilisation of milk, referred to in our columns a few weeks ago, was first carried out with uni-directional combined with slow alternating electricity, and researches show that the best results are obtained by the use of a rapidly alternating current.

THE CULT OF METHUSELAIH.

According to Professor Mackenzie, the secret of old age consists in a diet of beneficent beets.

When golden youth has flown
And you're bound at last to own
That your way of life's decisively down-hilly,
Though your hair is turning grey,
You can keep old age at bay.

By a diet of beneficent beet.

With fearful pains and care
You must regulate your fare,
Nor relax your keen precautions for a minute;
Not a mouthful should be missed.

By a practiced analyst.

Lost a stray unfriendly microbe should be in it.

But, before your hat you bow
To the secret Methuselah.

And try his plan your tale of years to double,
It may come to a terminus,
The question to decide.

If life like that is really worth the trouble?

Daily Express.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 1st.

British Ophthalmo-Laryngological Society (1 Chandos Street, Cavendish Square, W.-) 4 p.m.—Case.

TUESDAY, JULY 7th.

Royal Society of Medicine (Section of Obstetrics and Gynecology) (1 Wimpole Street, W.)—8 p.m.: Papers by Dr. Stainless, Dr. Malcolm, and A. S. Green, Chief Registrar, Short Communications by Dr. Archibald Leitch, Dr. Donald Roy. Vote of thanks to retiring Officers. The President's Annual Address. Members of the General Meeting of the Fellows will be held in the Robert Bruce Hall, I Wimpole Street, on Tuesday, July 7th, at 5 p.m.

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Greenwich (Drury Lane) Galway Union.—Medical Officer of the Shipdhan Dispensary District, salary £120 per annum, with extras amounting to £5 per year. Applications to R. F. Mullery, Clerk of Union.

Sunderland Borough Asylum.—Assistant Medical Officer. Salary £225 per annum, with the usual allowances. Applications to the Medical Superintendent, Borough Asylum, Ryhope, Sunderland, W.R.

Manchester Northern Hospital for Women and Children.—House Surgeon. Salary £120 per annum, with apartments and board. Applications to Mr. Hubert Tugend, Secretary, 36 Burton Arcade, Manchester.

Keat County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, board, attendance, costs, gas, garden produce, milk, and washing. Applications to Medical Superintendent, Asylum, Maidstone.

Bristol City Asylum.—Second Assistant Medical Officer. Salary £200 per annum, with furnished quarters, board, attendance, and washing. Applications to the Medical Superintendent, Asylum, Maidstone.

North Lonsdale Hospital, Barns-in-Furness.—House Surgeon. Salary £200 per annum, with furnished quarters, board, and lodging. Applications to the Secretary, T. W. Ingham, 5 Southgate Street, Rotham.

Rotherham Hospital.—Senior House Surgeon. Salary £200 per annum, with board, lodging, and washing. Applications to the Secretary, G. W. Roberts, 8 Norfolk Street, Rotherham.

North Manchester Hospital, Manchester.—Assistant Medical Officer. Salary £200 per annum, with furnished quarters, board, attendance, and washing. Applications to the Medical Superintendent, Asylum, Maidstone.

Royal Albert Hospital, Devonport.—House Surgeon. Salary £200 per annum, with furnished quarters, board, and lodging. Applications to Mr. Frank Taylor, 56 Upper Richmond Road, Putney.

Salop Infirmary (Country Hospital).—House Physician. Salary £110 per annum, with board and apartments. Applications to Mr. John Jones, Secretary, Board Room, Salop Infirmary, Shrewsbury.

Appointments.

Dr. Dennis, Henry, M.D., B.S., Lond., M.D. Bristol, M.R.C.P., Medical Superintendent, the Royal Borough Asylum.

Mr. Fenton, Thomas Gerald, F.R.C.S. Eng., L.R.C.P. Lond., Senior Surgeon of the Nuns Monastery District of the County of Middlesex.

Dr. Findon, Thomas, F.R.C.S. Eng., L.R.C.P. Lond., Certifying Surgeon under the Tuberculosis (Sanatorium Benefit) Scheme of the County of Middlesex.

Mr. Ashton, Thomas, T. W., M.R.C.S., L.R.C.P. Lond., Anæsthetist to the Western Orthopaedic Hospital, London.

Mr. Mowbray, Harold, M.D. Edin. Additional Radiographer to the Royal Chest Hospital, City Road.

Dr. Roberts, C. Herbert, M.D., F.R.C.S. Eng., L.R.C.P. Lond., Examiner in Midwifery and Diseases of Women to the Joint Board.

Dr. Stevens, T. G., M.D., F.R.C.S. Eng., Obstetric Surgeon to St. Mary's Hospital, Paddington, W.

Births.

Dr. Willcox.—On June 29th, at 27th, 146, St. James's Street, Settlement, the wife of Dr. Willcox, of a daughter.

Dr. Carver.—On June 16th, at 9a. Terrance, Torquay, the wife of A. E. Carver, M.D., of a son.

Dr. Cole.—On June 22nd, at Laurent Mount, Sh. H. Cates, the wife of Joseph Cole, M.D., D.P.H., of a son.

Dr. David.—On June 21st, at "Linda," Westhill Road, Torquay, the wife of Arthur E. Dratt, M.R.C.S., of a son.

Mr. Porter.—On June 30th, at 36 Queen's Rd, Dalston, to James Houston Porter, M.R.C.S., L.R.C.P., and Mrs. Porter—a son.

Marriages.

Deaths.

Dr. Allen.—On June 26th, suddenly, at North Parramatta, N.S.W., L. H. Dr. Allen, M.R.C.S., L.R.C.P., Lord, youngest son of the late Charles John Allen, to Mrs. Allen, daughter of Mr. W. J. Allen, M.D., formerly of 39 Trafalgar St., Melbourne.

Dr. Frie.—On May 5th, 1914, at Hampstead Hospital, Emery Norbert, M.D., dearly beloved husband of Maud Tresilian Frie, L.R.C.P. S. E.

Firth.—On June 26th, at Hindhead, Dr. Carl Firth, formerly of the United States, to Mrs. Firth, of 33 Barnett St., Brentford.

Margaret.—On June 26th, at "Cater," Brent Knoll, Somerset, the wife of Henry Margaret, to Blanche Katherine, eldest daughter of the late Robert Bruce, Esquire, M.D., F.R.C.S.E., Edinburgh.

HUME DISPENSARY.

Dale Street, Stretford Road, Manchester.

WANTED a HOUSE SURGEON daily registered and fully qualified. Salary £100 per annum. Annual increase £10 for every five years, with apartments and gas. Applications, with testimonials, at once to Honorary Medical Secretary.
The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX"

Vol. CXLIX. WEDNESDAY, JULY 8, 1914. No. 2.

Notes and Comments.

The letter from Sir Lauder Brunton published in the last issue of the Medical Press and Circular throws a lurid light upon the way in which the list of "contributors" to that popular work was drawn up. He practically disclaims any authorisation whatever for the use of his name, and quotes verbatim documentary evidence from the editor placing the blame for objectionable advertising upon the publishers, Messrs. Harmsworth. It may be pointed out, obiter, that these "explanations" do not account for the hardly less objectionable list of names of contributors, with titles and professional appointments, that appeared on the front of the 2nd and 3rd fortnightly parts. Was Dr. Riddle to blame for that lapse from professional ethics or is that also due to the publishers' excess of enthusiasm? In the latter case, surely Dr. Riddle could have deleted the list after its appearance in the first number. The persistence of the list with the reference to the medical books of four authors, during three numbers, that is, six weeks after the matter had attracted general attention and criticism, demands further explanations from Dr. Riddle. So far as Sir Lauder Brunton is concerned, his account shows that he was the victim of those responsible for the production of the Encyclopædia. It is not easy to understand why other "contributors" have not come forward with explanations of a similar kind.

The Duty of Medical Journalism.

Whichever course be taken by other leading medical journals in this country, we have remained faithful to the out-spoken policy of the Medical Press and Circular, which for nearly a century has endeavoured to uphold a high standard of professional ethics. Sir Lauder Brunton's letter shows that the matter has received the attention of the Royal College of Physicians of London. It may perhaps be presumed that other corporate qualifying bodies—including both colleges and universities—will also ask for an explanation from those medical men, whose names have been associated—voluntarily or involuntarily—with the "Family Encyclopædia of Medicine." As we have all along insisted, there is no moral offence in the advertisement of medical men in by publications; the British Medical Journal recently published a sort of guide as to where and how such publication was ethically permissible. This statement we found quoted in a Scotch lay newspaper, but we failed to discover it in a single newspaper published south of the Tweed. The rules of the ethical game, then, have been reduced to some sort of written form—so
that the contributors can learn precisely and exactly upon what ground of established professional opinion they could take legal action if that course were decided upon. Failing the vindication of a law court it is surely incumbent upon the "contributors" to the "Encyclopedia" to follow Sir Lauder Brunton's example, and to publish a full and particular account of their personal appearance in public under circumstances of so unusual a nature.

LEADING ARTICLES.

CRIME AND MENTAL RESPONSIBILITY.

Last week a man named Marjoribanks was sentenced to three years' penal servitude and seven years' police supervision on a charge of obtaining goods by false pretences. There is nothing of unusual interest in the actual crime of which the prisoner was convicted, the offence being that of stealing a cheque-book, by means of which he passed a number of forged cheques. A special feature of the case, however, arises from the astonishing criminal record of the man, an architect by profession, and a member of a well-to-do family. At the present time he is only thirty-four years of age, but he has contrived to perpetrate a series of crimes that is in its way probably unrivalled in the annals of criminology. He first came under the notice of the police in 1896, and the longest period he has been at liberty since was stated in court to have been one month. His offences were of a most varied nature, many of them dealing with forged cheques, by means of which tradesmen were induced to supply him with goods. He assumed many aliases, including the names of military and naval officers and of noblemen. Judging from the police report, his offences were in the main those of a man of some intellectual force, and they were apparently carried out with great daring and skill. Of his power of organisation and his reckless courage the police have had several unpleasant experiences. In Maidstone Prison he was the ringleader of a riot amongst the prisoners, to quell which the governor had to call in a company of soldiers, who suppressed the outbreak at the point of the bayonet. In June last, again, he was being conveyed from London by train in charge of two police officers when he suddenly jumped from the carriage and made good his escape while the train was in motion. There is no need to enlarge upon the doings and the character of this unfortunate criminal. It may be well, however, to point the moral of his experiences by some reflections on the way in which society has dealt with his shortcomings. The first great fact that emerges from the sordid history is the absolute failure of criminal law administration as a deterrent. It has neither protected property nor reformed Marjoribanks. The next point that suggests itself is that of the mental responsibility of a man who seems to commit crimes habitually as ordinary persons play golf or go to the theatre. There is nothing to show that the state of this man's mind—his sanity, his mental and moral responsibility—has been investigated by any expert or person fitted to speak authoritatively on the point. As a matter of fact, the legal mind is slow to grasp the idea of mental irresponsibility. If advanced in court, a plea of the kind has to face a hostile battery of criticism from counsel and bench, and is often met by a pitiful display of contradictory expert evidence. In any well-considered system of criminal law administration there should surely be some permanent expert body available to determine the question of a prisoner's sanity. Without some such machinery there is the danger of individual injustice in all criminal courts, from the lowest to the highest. The action of such an expert body should be automatic, for, from the very facts of the case, an accused person would not be likely to plead insanity of his own accord. The subject cannot, of course, be more than glanced at here. Clearly, it is one of considerable social importance, and it is to be hoped that among the sweeping reforms that are needed in the procedure and the administration of the law, that of the determination of mental responsibility will receive due attention.

THE ANNUAL ELECTION AT THE ROYAL COLLEGE OF SURGEONS, ENGLAND.

It must be conceded that much general interest centred around the annual election at the College on Thursday last, a fact which was not surprising. In the first place, there was a record number of candidates competing for five vacancies. Again, just at the last moment, an element of political flavour was introduced by an appeal from the Society of Members, urging the Fellows to support three candidates who had intimated their intention, if elected, to favour the claims of the members for some share in the government of the College. This was the first occasion upon which such an appeal had been openly made. It was brought under the notice of the constituency by a circular issued at the beginning of the week. Again, a second record was established as showing the interest which the election had created. No fewer than 1,037 Fellows recorded their vote. The number of Fellows on the roll of the College is about 1,600, that is to say upwards of 61 per cent. took part in the election. The result of the poll was declared by the President of the College, Sir Rickman Godlee, as follows:—Mr. William Thoburn (Manchester), 534; Mr. Chas. A. Ballance, 434; Mr. W. McAdam Eccles, 351; Mr. J. Stanley Boyd, 337; Mr. Chas. Ryall, 304; Mr. J. B. Lawford, 256; Mr. T. J. Openshaw, 245; Mr. W. G. Spencer, 238; Mr. Raymond Johnson, 218; Mr. F. F. Burghard, 204; Mr. F. J. Steward, 177; Mr. H. S. Pendlebury 106; Mr. T. H. Kellock, 99; and Mr. P. M. Yearsley, 90. The five first named were successful, and to these we offer our congratulations. In reviewing this remarkable contest, one or two points suggest themselves for notice. The first is the success of the provincial candidate who heads the poll. As we pointed out
a week ago in these columns, a provincial candidate ought always to be successful; the success of such a candidate is merely a matter of agreement among the Fellows in the provinces, who greatly outnumber those within the metropolitan district. The provincial representation on the Council has always been a negligible quantity, for which the provincial Fellows have only themselves to blame. We believe that each large medical school in the provinces might with advantage in turn run a candidate at these elections; if this were done, as it might be, by organisation, the impression that the Council is practically a closed borough for the surgeons of the metropolitan schools would soon receive its quietus. The next point claiming attention was the intrusion at the last moment of the appeal of the Society of Members. The circular requesting the Fellows to vote for three candidates who had expressed their sympathy with the members' claims contained the following paragraph:—

"To govern a great College there is needed a body of men of wide and comprehensive intelligence. To secure a Council of such men we must avoid those persons whose only idea is to glorify their own existence and to remain deaf to all suggestions for improving the College administration, and who refuse to adopt the only course which will make the College of Surgeons a real power for inspiring surgical knowledge and for protecting and guarding surgical practitioners." It is not unnatural that the members should think themselves worthy of a share in conducting the affairs of the College, and that their inclusion would not lower the position, academically and professionally which it occupies at present. It is a matter of some regret that members have failed in this instance to formulate a clear and moderate policy, which might have advanced their cause materially. A plain statement of the main reasons actuating the members to claim a share in the government of the College might possibly have influenced many Fellows in their favour. The Royal College of Surgeons of England is ancient enough to require those fundamental changes in its constitution which sooner or later are essential to all corporate bodies, that is to say, if they are to keep abreast of social evolutionary thought and movement. Most of all is salutary reform needed in a body that is intimately connected with so progressive a subject as that of surgery.

CURRENT TOPICS.

A most interesting display of pathological specimens consisting of recent additions to each section of the Museum of the Royal College of Surgeons of England, is now on view in the Hall of the Museum and in Room 1. In his annual report, Professor Arthur Keith, the Conservator, states that the scheme of re-arrangement of the entire pathological collection, sanctioned by the Council four years ago, is on the eve of completion, so far as it relates to the section of general pathology. Some thirty-two cases now hold this latter collection, and others illustrating the biology and experimental creation of neoplasms and the effects produced by the introduction of foreign bodies into living tissues and organs are now in process of being arranged. Special mention may be made of the important gifts received during the year. The "corrosion preparations," illustrating the structural details of the human body, prepared by Dr. Wahby, Professor of Anatomy in the Egyptian Government School of Medicine in Cairo, are on view, and also the curious specimens prepared by Dr. Edward Smith, of the Department of the Library, at Washington, U.S.A., showing the occurrence in plants of tumour formations of a malignant nature. Both these exhibits were to be seen in the Museum of the International Medical Congress held in London in 1913, where they excited much interest. The preparations made by Dr. Wood Jones, of the uro-genital system of animals presented by the London School of Medicine for Women, and the first model made by Mr. E. T. Newton, F.R.S., showing the detailed anatomy of the brain of the common black-butterfly, are well worth a careful examination. Considerable interest is being taken in the specimens of the male pheasants, presented by His Majesty King George V. The Archaeological Survey of Nubia and the Egypt Exploration Fund have continued their liberal support. Altogether the exhibition is one which deserves at least one visit from medical men and scientists.

Unprofessional Conduct.

There are many occasions on which the conduct of a medical man, while coming short of what would be considered "infamous" by the General Medical Council, is yet what some might truly describe as "unprofessional." It is of some interest to discuss what should be the attitude of members of the profession towards a man whose conduct is habitually or deliberately unprofessional. The conduct must, of course, be habitual or deliberate, for small breaches of etiquette are better ignored. A particular objectionable action may have happened by inadvertence, and medical men should not be too touchy. Where, however, the commonsense of the profession decides that a particular line of conduct deliberately pursued is unprofessional, it is necessary to take steps to bring the fact home to the offender. In the first place, he should be given an opportunity of explaining his conduct, or of withdrawing from it, and, if necessary, expressing regret. The proper steps for such a purpose are best taken by the local medical society, if there be one. We assume that all this has been done, and the offender remains obdurate in his evil courses. What steps are his brethren now to take? In the first place, it is inconsistent that he should remain a member of any medical society which regards honourable conduct as an essential qualification in its members. In the next, honourable medical men will withdraw from him those privileges of courtesy and comradeship which it is customary for one medical man to extend to another. He has abused the privileges of the profession, and he is no longer entitled to them. His withdrawal of comradeship, or refusal to assist or consult really punishes the offender's patients, and not himself. This is not so. A patient can choose...
between one doctor and another. If one doctor, by his own action, has deprived himself of certain privileges open to others, it is a matter his prospective patients must weigh in choosing him to attend them or in retaining him in attendance when they learn of his limitations. We will add just two observations on this subject. One is the impossibility of accepting charge of a patient a medical man has absolutely no responsibility toward him. The other is that if an honourable medical man, out of pity for a sick person, thinks it is obligatory on him never to refuse to meet any practitioner, however disgraceful, in consultation, he must hold himself equally bound to meet the herbalist and the bone-setter.

Work.

Work is doing things because we must. They may be things we like doing or not, but the essential thing about them is their necessity. Willy-nilly work is what we must do. When we do it is another question. Sometimes we must do it now, even eagerly and finally; often we can leave it over till to-morrow. Some of us work for a fixed time and know that, once closing time has come, we are free till the clock comes round again. We often like our work, or even enjoy it. But we feel that enjoyment is furtive and forbidden. "In the sweat of thy face shalt thou eat bread." That was a curse; but we are not dejected as if Hampton Court perspirings a pleasure. The Germans—paddling race who often miss the price—have been investigating work. They have been trying to determine the best time for it—a futile waste, for only the few can choose. They agree that the morning is the best time for mathematics or mechanics, and that a tired mind cannot remember. They are satisfied that school children should not work at night. It is worse than a waste of time, and the effort to make the brain work at all is absolutely harmful. Evening is story time, and always was from troglodyte days. The imagination is unfenced, and wafters in the pastures of the stars. But many men tear up in the morning what they wrote the night before. We should have many philosophers at the breakfast table. We do not, because they are not properly awake. All these results are no doubt worth knowing, and their authors have done some little thing to advance knowledge. But most of us cannot feel the time for that. We must; and our more casual fellow-workers work when they feel like it, or when there is nothing better to do. Anyway, it can do no harm to record the facts.

The Problem of the Germ Carrier.

From the public health standpoint much interest has centred around those individuals who, all unconsciously, scatter the germs of disease and death broadsheet. Whether he has or has not suffered from a but terminal infectious disease, the chronic germ carrier who bears in his alimentary or his urinary tract the micro-organism of that disease is a distinct source of danger to the community. In regard to the milk-supply, for instance, it has been shown that outbreaks of infectious disease have occurred from time to time as a result of the employment of infected persons, if not actually contagious from enteric fever, have nevertheless been carriers of the Bacillus typhosus. It is just in relation to cases of this description, as Mr. Herbert Samuel pointed out the other day in a Standing Committee of the House of Commons to discuss the Government Milk and Dairies Bill, that greater powers of inspection should be provided. The subject was also referred to last week in a lecture before the Royal Institute of Public Health, by General L. Vaillard, the President of the Board of Health of the French Army, who gave an apt illustration of the danger of disease carriers in the case of a certain cook, a chronic typhoid carrier and also a carrier of the Bacillus typhosus, who was said to have been responsible for five epidemics of enteric fever in nine years, having been engaged in the preparation of ice-creams for wedding parties and banquets. In the case of diphtheria it is well known that the bacilli are carried in the faces of healthy individuals in times of epidemics of that disease. Scientifically Bacon was the first of the great iconoclasts, and after him there was a deluge of disrupted matter. Analysis was endemic, and men saw nothing but the marvels of simplicity. To-day we have experimentally smashed almost all our surroundings, and we are trying to put them together in new ways. There are drugs and bacteria and passionate people no less ingenious than their composition, while their alleged qualities are more wonderful than all.

We have synthetic sugar and synthetic rubber; we have heard of synthetic milk—made chiefly from a Chinese bean—which is an ever-present dread. There was an American who tried to manufacture eggs. The yolk, the white and the shell he could do "on his head." He stuck at the skin. He finally perfected it, but the cost of the necessary rubber ruined his enterprise commercially. Synthetic life is no new idea. Men have striven to imitate the masterpiece of the Ancient of Days with soap and oily films. Their amoral moved and were still. They have had and still have the Internationale de la Tuberculose. Dr. Alexandre Marie has made "asaetically by the action of the tuberculin of the Pasteur Institute upon sterilised glycerophosphate of soda" bodies identical alike in form and capacity for stain with Koch's bacillus. What is more marvellous, they grow on potato and guinea-pig's liver, etc. The one thing is true we must turn over our ideas. They are probably not true, but nowadays it is more popular to believe than to doubt. "Go round." That is the real way to knowledge. Swift used to call the man who made two blades of grass grow where one did before a benefactor of the human race. We wonder if the same comment is applicable to the multipliers of tubercle bacilli.

Sanitation in Camps.

In view of the increased number of organisations that arrange for the spending of summer holidays in camp, the sanitary conditions of camp life may well receive more attention from health authorities than has hitherto been bestowed upon them. Some excellent rules with regard to camp sanitation have recently been issued to officers of the East Anglian Division of the Territorial Force, and published in
full in The Medical Officer. Under the heading of “Responsibility” each unit and the individuals composing it are urged to study sanitation and the laws of the preservation of health. Great stress is laid upon the importance of the prevention of contamination of food and drink. Food and excesses must be avoided, the latter especially in regard to meat, jams, sweets, tobacco, alcohol, lemonade and cold water. Extra food, such as coffee and biscuits before early parade, and fruits and fresh vegetables are to be encouraged as conducive to health and efficiency. The dangers of refilling water-bottles from just any source and also of filters, except under medical supervision, are pointed out. Some sound advice is given in the matter of the disposal of refuse, as well as in the elements of personal hygiene. Whenever possible opportunities for personal cleansing should be provided and used. A debilitated unit from want of rest or neglect of some vital sanitary principle will figure badly in manoeuvres and will be useless in time of war. Attention to the rules and elementary principles of military hygiene will do much to promote the health and good spirits of men, and the same applies, though to a lesser extent, to boys’ summer camps.

The Plasmodium Tenue.

As important communication was made at a recent meeting of the Royal Society with respect to a new malaria parasite infecting the human subject. This new organism was discovered by Dr. J. W. Stephens, Sir Alfred Jones, Professor of Tropical Medicine in the University of Liverpool, in a blood slide sent to him from a native child from Pachmari, Central Province, India. The peculiarity of the Indian parasite appeared to be its irregularity as compared with the regular, almost monotonous, conformational “rings” of the malignant tertian parasite (Plasmodium falciparum) which it resembles at first sight. In a series of consecutive drawings made by Professor Stephens of each parasite the specific differences of the new organism become apparent. Its most conspicuous features are that it is extremely ameboid, the cytoplasm is always scanty, the parasite having little bulk or density, and the nuclear chromatin is out of all proportion to its volume, being abundant in quantity and very irregular in its distribution. Typical rings are absent or exceedingly rare. It is doubtful, at present, whether the parasite be pigmented or not. After a prolonged study of the morphological characteristics of the organism, it is concluded that it is differentiated thereby from any other malarial parasite of man. The name proposed for it is the Plasmodium tenue. Other points regarding its morphology must necessarily remain unsettled until further material be forthcoming.

PERSONAL.

DR. R. A. ASKINS has been appointed whole time School Medical Officer to the Bristol Education Committee.

DR. CHARLES NYMAN, of Ebbe Vale, has been appointed Medical Officer of Health for Brynmawr, in succession to the late Dr. M. Sheedy.

In memory of their father, Sir William Lawrence, F.R.S., Surgeon-Surgeon to Queen Victoria, and of their brother, Sir Trevor Lawrence, long Treasurer to St. Bartholomew’s Hospital, the Misses L. E. and M. W. Lawrence have presented £4,000 to the Royal Society for research into the cause and cure of disease.

DR. T. DIVINE, of East Hull, was the recipient last week of a suitable testimonial in recognition of his valuable services as Hon. Secretary of the local Medical and Panel Committee in connection with the working of the National Insurance Act.

SIR HENRY LINN, M.D., has purchased the Bridge of Allan Hydropathic, and intends to open it this month under the name of the Allan Water Hotel.

MR. HOWARD JONES, M.B., B.S.Lond., M.R.C.S., L.R.C.P., has been appointed Honorary Anaesthetist to St. Mark’s Hospital for Diseases of the Rectum.

MR. JAMES B. HOWELL, D.P.H., M.R.C.S., L.R.C.P., Assistant Medical Officer of Stepney, has been appointed Medical Officer of Health for Hammersmith.

DR. EVAN ABLAS was the recipient the other day of a suitable presentation from his many friends at Lindfield, Sussex, upon the occasion of his relinquishing practice in the district.

A HANDSOME monument, in the shape of a clock tower, to the memory of the late Mr. Walter Whitehead, the well-known Manchester surgeon, was formally presented to Bury last week.

DR. THOMAS DRUSLYN GRIFFITHS, M.D., D.Sc., of Fern Combe, St. Stephen’s Road, Bournemouth, a former President of the British Medical Association, left the estate of the gross value of £2,046.

DR. A. P. BEDDARD, M.A., M.D.Oxon., F.R.C.P., Lond., and Dr. E. P. Poulton, M.A., M.D.Oxon., M.R.C.P.-Lond., have been appointed respectively Physician and Assistant Physician to Guy’s Hospital.

DR. JAMES FULTON, of Woodvale Road, Belfast, was the recipient the other day of a handsome testimonial in token of the high esteem and respect in which he is held by the district. A suitable presentation was also made to Mrs. Fulton.

DR. J. W. ASLEY COOPER will open a discussion at the meeting of the Society for the Study of Inebriety to be held on July 14th, at 4 p.m., in the rooms of the Medical Society of London, 11 Chandos Street, W., on “Proposed Legislation for Inebriates.”

The following medical practitioners have been placed in the Commission of the Peace for Glamorgan by the Lord Chancellor:—Drs. Peter J. O’Donnell, S. G. Morris, County Alderman Thomas H. Morris, D. N. Morgan, County Councillor W. Evan Thomas, and R. D. Price.

CIVIL LIST Pensions have been awarded to the widows of Dr. R. H. Traquair and Professor N. H. Alcock, M.D., respectively, and also to the daughter of the late Dr. E. H. Willoughby, in consideration of the valuable services rendered by the deceased to medical science as well as in consequence of the inadequate means of support of their survivors.

The following members of the medical profession have been appointed upon a Committee appointed by the War Office to inquire into the working and organisation of voluntary aid detachments:—Colonel Sir George T. Bentzon, K.C.B., Col. Sir John T. Clark, Bart., Major Sir Anthony A. Bowley, C.M.G., and Surgeon-General W. G. MacPherson, C.M.G. The Secretary is Lieutenant-Colonel G. B. Stanistreet, R.M.C.

MISS SELINA FOX, M.D., at present Superintendent of the Bermessey Medical Mission, has been appointed by the Home Secretary, on the recommendation of the Prison Commissioners, Lady Superintendent and Deputy Medical Officer of the institutions for women at Aylesbury, comprising the Female Convict Prison, the Borstal Institution for Females, the State Inebriate Reformatory for Women, and the Preventive Detention Prison for Women.
CLINICAL LECTURE.

ON

BRONCHIAL DILATATION.

By M. CASTAIGNE, M.D.,

Physician to the Beaujon Hospital.

[SPECIALY REPORTED FOR THIS JOURNAL.]

Cases of simple bronchial dilatation have become rare since we took a look at the subject. Delboeuf and Grancher demonstrated the fact that in most instances bronchial dilatation, or bronchiectasis, is of tuberculous origin, at any rate in adults and elderly people.

A patient, 64 years of age, a baker, came to us the other day with a history of having suffered from bronchial dilatation for upwards of thirty years. In the course of his life he had had a whole series of diseases. At 10 years of age he suffered from febrile attacks ascribed to malaria, and, as we know, a relationship betweenague and bronchial dilatation has been remarked more than once. Then, too, Hustin showed that bronchial dilatation, common enough in children, may reappear in the adult, so that this detail is not without importance.

In 1884, when 30 years of age, this patient had an attack of broncho-pneumonia which seems to have been the starting point of the dilatation, for the attack was protracted and was followed by a relapse since which he has always had a chronic cough. But we must not omit to mention that he has been under treatment at the Ricord Hospital for troubles presumably of syphilitic origin.

At the present time the patient complains of cough and copious expectoration. Directly he wakes in the morning he is seized with a harassing cough accompanied by copious expectoration—as much as a tumblerful, he tells us. This presents the characteristic appearances of the expectoration in bronchial dilatation—that is to say, it usually separates into three layers: a lower one which is frankly purulent, a middle layer which is clearer, and a frothy upper layer.

He tells us that, like most of his fellow-sufferers, he is obliged to take certain precautions at night in order not to be awakened and worried by this convulsive cough. It is generally stated that these patients prefer to lie on the affected side, but the contrary is often the case, and that is the case in this instance, for he tells us that he is more comfortable on the opposite side.

In conjunction with these functional signs it is to be noted that there is no haemoptysis. Now, haemoptysis is certainly more frequent in cases of tuberculosis, but we must not forget that it is also met with, and this by no means rarely, in cases of simple bronchial dilatation. In support of this statement we might quote the classical observations of Hanot and Gilbert, which are conclusive inasmuch as they were confirmed by post mortem examination.

We will now pass on to the physical signs, and here it should be noted that when we are dealing with a tuberculous patient with such copious expectoration as this we generally find a cavity, and this cavity is at the apex of the lung. Here, on the contrary, there is no trace of a cavity at the apexes—or, indeed, any suggestion of breaking down. The physical signs are limited to the left base. At the right base we only hear occasional sibilant rales and signs of pulmonary emphysema.

At the left base we note retraction of the chest wall with well-marked dulness extending into the axilla and exaggeration of vocal fremitus, and on auscultation we hear gurgling sounds, which are louder when the bronchus is partially filled and are at times quite cavernous.

Apart from the clinical signs, other physical means are available for the purpose of verifying the information afforded by percussion and auscultation, especially radiography. At first radiography was only made use of to detect pleural lesions, and from this point of view we know that it yields very valuable data. Then, little by little, as the process became more rapid, it became possible to utilise it in apoplexy for the differential diagnosis between a cavity and bronchial dilatation. This patient was, therefore, radiographed, and inspection of the photograph yields the following information:—The apices are clear, while the lower two-thirds of the lung present a series of patches due to sclerosis and suggestive of bronchial dilatation.

But what are the other clinical elements of the diagnosis? To begin with, we have to ascertain whether this broncho-pulmonary disease, which has been running on for thirty years, has produced in the patient the constitutional effects which we are entitled to expect in pulmonary tuberculosis. Now we find on inspection that his general health is good, seeing that during these thirty years he has been able to continue his work as a baker, a laborious calling, in which all the time he is inhaling dust which is irritating to the bronchi. Owing to this and sundry improprieties on his part, there have been superadded attacks of bronchitis, which have obliged him to lay up from time to time, but little is of this he has not lost strength to any great extent.

He presents very plainly the so-called Hippocratie fingers, that peculiar bulbous form of the finger ends due to the interference with haematoysis caused by bronchial dilatation. The heart is not the seat of any disquieting lesion, the patient is not threatened with asystole and his blood pressure is practically normal. Radiology shows a dilated, stretched aorta, a symptom which may be referred to his syphilis. Our assumption that we are dealing with a case of bronchial dilatation and not of tuberculosis is based on both the physical signs and the constitutional symptoms.

The physical signs are: The localisation at the base, whereas pulmonary tuberculosis mostly runs its course in one of the apices, the other showing signs of infiltration, the bases being pretty free. Here, on the contrary, the principal lesions are limited to the left base. This is already a valid reason for suspecting bronchial dilatation. But this is not sufficient. During the last few years it has been shown that we sometimes get tuberculous cavities at the base giving rise to very similar manifestations.

Nothing in this case justifies a suspicion that this might be tuberculous cavity at the base. The auscultatory signs are not quite the same, and radiography confirms this conclusion. Then, too, the
sum total of the functional signs is clearly in favour of its being a case of bronchial dilatation.

The constitutional signs militate in the same direction. The condition of a good state of the general health for thirty years without any spitting of blood and without oscillations of temperature is exceptional in pulmonary tuberculosis, while it is constant in bronchial dilatation.

Everything, therefore, points to the latter diagnosis, but there is one point which cannot be overlooked—viz., the presence or otherwise of the tubercle bacillus. Now, repeated bacteriological examination has invariably proved negative.

But although we have now arrived at the diagnosis of bronchial dilatation, this is, after all, an incomplete diagnosis, since we have merely diagnosed an anatomical lesion which may be due to various causes. At the present time we can distinguish between ordinary and specific causes—the latter comprise syphilis, tuberculosis and a recently discovered affection, oosporosis.

A tuberculous origin has been excluded in this case, but he may easily become tuberculous in certain environments. Nor is all certain dilatation with tuberculosis, says Grancher. It would be more accurate to say that bronchial dilatation may in any instance be due to tuberculosis or may become tuberculous secondarily.

Syphilis has been incriminated on several occasions. Bensaude presented to the Medical Society of the University of Liverpool the following case which he had done before and after treatment, of a patient with dilatation of the bronchi associated with syphilitic sclerosis of the lung, who greatly improved under specific treatment. We must therefore bear syphilis in mind, and here the dilatation of the aorta is in favour of syphilis. The Wassermann test would give us useful information, and if the case might serve him on treatment. But we are not entitled to invoke syphilis solely, it is a secondary infection which has acted on an organism previously enfeebled by chronic bronchial dilatation.

Oosporosis has been investigated principally by Professor Roger and his pupil, Bory who, in a series of cases of bronchial dilatation discovered peculiar rods in the sputum and identified the peculiar rods of the *oospora pulmonalis*. In these cases iodine is remarkably efficacious.

In the case of this patient, we may conclude that it is one of bronchial dilatation of the ordinary kind consequent upon a broncho-pulmonary affection. It seems that acute broncho-pulmonary affection which has already existed, and which may be due to dilatation. Hutinon has shown that this is the case in children, but in adults it does not appear that acute inflammatory diseases can per se determine dilatation. It requires a slow chronic process or some, superadded cause. There was something of the kind in this instance in the shape of inhalation of dust.

Now, as to treatment. Our intervention can only be of service at the acute stage, during convalescence from the broncho-pneumonia. The patient must be watched, prevented from committing imprudences, and induced to quit any calling that exposes him to bronchial irritation.

At the advanced stage which this patient has now reached, all we can do is to protect him against secondary infections. The balsams and antiseptic inhalations are useful in order to ward off gangrene of the lung. It is only in the specific forms that we can hope to effect anything of the nature of cure.

During the last few years attempts have been made to intervene surgically. Pneumotomy has been performed, and gives good results in cases of superadded infection and actual abscess of the lung. But pneumotomy is not indicated here, nor could it be in the absence of such some complication. Tuffier has observed satisfactory results by milder means when the dilatation is strictly circumscribed—viz., by stripping off the parietal pleura and introducing adipose tissue in order to compress the bronchi. This might prove useful in a young subject not over 40, but certainly not in this instance.

Note.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Herbert French, M.A., M.D. Oxon., F.R.C.P., Physician to Guy's Hospital.

Subject: "Some Further Therapeutic Points."

ORIGINAL PAPERS.

CASES SIMULATING APPENDICITIS. (a)

By ROBERT E. KELLY, M.B., B.Sc., F.R.C.S.,
Assistant Surgeon, Liverpool Royal Infirmary, Lecturer on Practical Surgery, Liverpool University.

In reading a paper on appendicitis, one feels that one ought to apologise for treating a subject which has been written on in both lay and medical journals ad nauseam. The vast majority of the papers, however, are concerned either with the pathology or the treatment of the disease, and I thought that a short paper on some difficulties of diagnosis might be acceptable to a Society such as this, or at any rate serve as an introduction to an interesting discussion.

When the “New English Dictionary” was begun in 1884, the term “appendicitis” was unknown. At the present time appendectomy is the most frequently performed operation in any large general hospital. In the Royal Infirmary, during the year 1911, 200 cases admitted for appendicitis were operated upon.

In my personal experience of nearly 200 cases of the disease, I find that in a large majority a correct diagnosis has already been made. A small minority remains, however, in which the diagnosis is at fault, and it is my purpose and desire to-night to consider these cases of mistaken diagnosis.

They fall naturally into two distinct classes.

First, those in which immediate operation is undertaken; and, second, the interval cases.

The former or acute cases are amongst the most interesting of one's experience. It is, of course, highly disappointing, though often unavoidable, to disclose a healthy appendix where one expected to find it gangrenous. Fortunately, a further exploration of the abdomen generally suffices to localise the mischief.

The Interval Class.—This class comprises those cases which after one or more attacks of pain in the right iliac fossa are referred to the surgeon for operation during a quiescent period. Every surgeon will agree that a normal appendix has occasionally been removed under these circumstances. The fact that subsequently he may be called upon to operate for another condition affords a sufficient conviction that the previous diagnosis was wrong. Now it seems to me that a consideration of these mistakes in diagnosis will prove both more interesting and more instructive than a mere recital of successful cases. I have therefore collected the following from my own case books as a basis for my paper.

(a) Read before the Birkenhead Medical Society.
Of the acute cases I have seen pneumonia, hip-joint disease, kidney disease, and general infections mistaken for appendicitis. In regard to pneumonia one must always bear in mind the examination of the chest, especially in children.

In hip-joint disease, movements at the hip are limited in all directions; whereas, in appendicitis accompanied by flexion of the right hip-joint, the limitation of movement is found to be for extension only, rotation remaining perfectly free.

In kidney disease the diagnosis may be most difficult. A woman, aged 28, was admitted with a huge abscess extending from the mid-line of the abdomen over the right iliac fossa. On the loin on the right side. She had had it for six weeks. On evacuating this abscess the pus which was let out had a distinctly faecal odour, and in the pus were found four concretions. It seemed obvious from the smell which one usually ascribes to the B. coli and the concretions that this was a large appendix abscess. Subsequently, however, it became certain from the urinary discharge that what I had been dealing with was a pyelo-nephrosis, and that the concretions were urinary stones.

An X-ray might have saved this mistake in diagnosis, but incidentally I may mention that I have some appendix concretions which gave well-marked X-ray shadows in the X-ray examination. Of several infections I will only refer to two cases. Both were sent to the Royal Infirmary with a diagnosis of appendicitis.

The first was a boy, aged 14, who had been scalced on the dorsum of his right foot. It was treated at school with some ointment! Twelve days later he was seen by a doctor, who sent him to the Infirmary because he had a rigid right rectus abdominis muscle. The whole abdomen, however, proved to be stiff, and on making a rectal examination the boy showed marked opisthotonus. He was obviously suffering from tetanus, the result possibly of infection from the dressings used to treat his scalp. It is interesting that the stiffness of the muscles should first be seen on the same side as the injury. It was suggested that time (now five years ago) that tetanus should be treated by injecting the anti-tetanic serum over the Rolandic area. This was done, but whether it had anything to do with the boy's recovery I cannot say.

The second case was that of a boy also admitted with the diagnosis of appendicitis. He looked very ill. He had a raised temperature and pulse rate, and he was delirious. The hip-joint was normal. Locally, there was just above Poupart's ligament on the right side a tender brawny swelling, with the skin red over it. The swelling appeared lower than is usual in appendicitis. I suspected acute osteo-myelitis of the iliac bone. Instead of pus I found a mass of glands which I sent to the laboratory to have examined bacteriologically.

It was surprised to hear two days later that the glands were infected with the bacillus tuberculosis. The patient was isolated. No fresh development of cases occurred. Gastric and duodenal ulcers, Gall-stone disease, Acute pancreatitis, Intestinal obstruction, Tubercular and malignant ceca, and Diseases of the female genital organs.

My youngest and oldest cases of perforated gastric ulcer were both mistaken for appendicitis. The first was that of a boy, aged 10. The abdomen was of a board-like rigidity, the pulse-rate and temperature were both raised, the lips were blue, and his expression anxious. A stab wound over the pubis indicated free fluid in the abdomen, but an incision in the right iliac fossa revealed a normal appendix.

The stomach was therefore explored, and a hole found in the lesser curve about an inch from the pylorus.

In my oldest case there was at the time of operation a history of sixteen hours' pain in the abdomen. The patient stated that the pain began above the umbilicus; but when I saw him, just before operation, there was no pain at all above the umbilicus. It was entirely confined to McBurney's spot. Moreover, the whole of the right iliac fossa was exquisitely tender. On cutting down upon the appendix by the usual split muscle incision there was marked edema in the tissues of the abdominal wall. This appeared to me that in both these cases the patient's history and statements were not sufficiently considered.

I used to think that by making a small stab wound above the pubis in all cases of peritonitis one could tell by the smell of the free fluid in the pelvis whether one had to deal with a perforated appendix on the one hand, or a perforated stomach or duodenum on the other.

Though it is true, for the most part, that the fluid associated with appendicitis had the so-called rotten, faecal, faeculent, or fishy smell, it is not always true, for I have had cases in which the reverse condition was found.

We come now to cases in which a large, full gall-bladder is mistaken for an appendix abscess. Edith M., aged 25, admitted with a large, tender swelling under the right rectus muscle. Pulse and temperature above normal. In this case there was no history of indigestion or jaundice. She was sent in as an appendix case, and the diagnosis lay between a distended gall-bladder, an appendix abscess, or renal mischief. Operation revealed a very large gall-bladder surrounded by adhesions to the large bowel and omentum, and showing not only pus and stones in its interior, but also some free pus lying between the gall-bladder and the omentum.

In connection with gall-bladder disease, I had a case which presented some very unusual features. Jane H., aged 40, had been ill some days. No vomiting, but much excessive, sickening thirst. Abdomen hardly moving at all, and very tender in the right iliac fossa. Temperature 104, pulse only 90. Her doctor considered it appendicitis;
personally, I leaned towards gall-bladder trouble, as the greatest tenderness was rather above the umbilicus on the right side.

I therefore made a high split muscle incision, so that I might have access to either, should occasion require it. A very red and oedematous gall-bladder presented itself, evidently full of pus as well as stones; but on looking at the appendix region, although that organ itself was healthy, about ½ ins. above the ileo-cecal valve there was a hard mass in the cæcum showing a typical ring structure. This would, I thought, just admit a cedar pencil only, and would certainly give rise to intestinal obstruction after the operation, it left alone. Removal of the growth was out of the question. The condition of the patient would not admit of it. I made, therefore, a lateral anastomosis between the ileum and transverse colon. The gall-bladder was brought out through a separate small incision, and the pus and stones evacuated. About three weeks later I removed the growth. This, fortunately for the patient, turned out to be tubercular, and not malignant, as I had feared.

Another curious case was that of a girl, aet. 26. She gave a history of having had, three years before, a previous attack of pain in the abdomen which kept her in bed for a week. On the afternoon before operation, whilst shopping, she was suddenly seized with acute pain in the pit of her stomach. She was also some vomiting. She was seen by her doctor three hours later. The pulse rate was 80°, and the temperature 99. There was severe pain and tenderness over the appendix region, somewhat relieved by ½ grain of morphia. The doctor saw her again next morning. The vomiting had continued during the night. There was no permanent relief from the pain. The temperature had gone up to 100° and the pulse rate to 90. The tongue was dry and the abdomen rigid.

An operation for appendicitis was therefore advised. I agreed with the diagnosis, although when I saw her she had some pain and tenderness in the left iliac fossa. This I thought was due to the fact that her pelvis had filled with fluid, and was now irritating the left parietal peritoneum. At the operation the appendix was normal, but there was free inodorous dark-brown fluid in the abdomen. A second incision above the umbilicus was made to ascertain if she had a perforated gastric ulcer, but both the stomach and duodenum were normal. The omentum, however, showed extensive fatty necrosis, and the pancreatic head was glazed with lymph, and somewhat swollen. On further exploration some stones were found in the gall-bladder, so a third incision was made over this organ and twenty stones removed. A fourth incision, a stab wound over the pubis, was made to drain the pelvis, and continuous salines instituted.

This patient exhibited what one might consider a typical history of appendicitis. If the condition of acute pancreatitis had been correctly diagnosed, she would at least have recovered with two scars the less.

I will now consider intestinal obstruction simulating appendicitis. The first of these is the case of a girl, aet. 8, who was seized with acute abdominal pain after partaking of some fruit. Purgatives failed to give relief, and she came into hospital with a lump in the right iliac fossa. Pulse 140°, temperature 101. Intestinal obstruction was complete. The abdomen was moving normally. She looked very ill, and immediate operation was advised. The lump which had been diagnosed as an appendix abscess was found to consist of six or seven coils of small intestine, with mesenteric thrombosis, I resected the gut, but without avail, the girl dying of operative shock some hours later.

Another interesting case was that of a boy with almost the same history and objective signs as in the case just mentioned. At the operation the tumour consisted of a mass of coils of small intestine, with thickened and oedematous walls. There was, however, no thrombosis. This turned out to be a case of Henoch's purpura in which the rash did not appear until after the operation.

These cases of Henoch's purpura are somewhat rare, but the mistake of operating on them as cases of appendicitis or intussusception is common.

One must always bear in mind that cases of intestinal obstruction may depend on the sequelæ of appendicitis. A man, aet. 50, was admitted for intestinal obstruction of five days' duration.

There was marked distension of the bowel and a lump on the left side of the abdomen the size of an orange. This patient was found to have a mass of adherent coils of intestine and omentum surrounding some fætid pus produced by the bursting of an appendix near the ileum. This had occurred when the appendix had roamed into its anatomical position, pointing in the direction of the spleen.

Diseases of the cæcum are also common causes of mistaken diagnoses.

The tumour formation of both malignant and tubercular cæca are very apt to be mistaken for appendix abscesses. Sometimes, indeed, the malignant disease may have engraved on it some pus formation. A diagnosis of appendicitis in the aged should always be attended by a grave prognosis.

About two years ago, I was asked to operate on a case of appendicitis in a woman, aet. 55. On inquiry, I found that the obvious lump in the right iliac fossa had been there for four months. She had had temperatures, but the lump was so hard that I diagnosed the condition as one of malignant disease. This was further strengthened by the presence of visible peristalsis. On exposing the lump, the growth was so firmly fixed to the posterior abdominal wall that I had to content myself with an enterotomy. Almost exactly twelve months later her doctor told me that the lump had entirely disappeared. I closed the enterotomy.

I, unfortunately, have no evidence as to the nature of that case, but I believe that it was a tubercular cæcum, mimicking, as it sometimes does to a remarkable degree, malignant disease. The cure of the condition followed on the rest given to the cæcum by the enterotomy.

We have in the infirmary at the present time a girl who was admitted with a large tender swelling extending from the loin to the right iliac fossa. It was breaking down on the surface, and the diagnosis lay between disease of the kidney or the appendix. At operation the pus showed typical actinomycosis granules.

The disease had probably commenced in the cæcum.

Lastly, I would like to say a few words about the very common error of operating for appendicitis and finding disease of the genital organs.
The very first abdominal operation I ever did was that of a young woman with all the signs of acute abdomen. I felt uncertain as to the cause, and was fortunate enough to have the help of the gynaecologist. We came to the conclusion that as we thought that the appendix was at fault I had better do the operation. I had to remove two large Fallopian tubes distended with pus. I have repeated this error since on two other occasions; but perhaps I may be pardoned if I tell you that they were both in single women.

In another case of pyosalpingitis occurring nine days after confinement, the resemblance to an appendix tumour was remarkable, for the right and diseased tube was 6½ ins. long and 2 ins. thick, and lying on the side of the still enlarged uterus was exactly in the position of the appendix and appendix. Moreover, the pus from this tube, which burst just as I was getting it out of the abdomen, had a distinctly foetid odour.

In another woman, at 36, also sent in as a case of appendicitis, I had to remove a ruptured ectopic pregnancy.

Even in the male I have operated on a man who had a previous attack of pain over an undescended testicle.

It had been called torsion of the testicle. On opening the abdomen the testicle was found bound down by adhesions to the posterior abdominal wall and to the cecum, but in the midst of the adhesions there was an appendix covered by omentum, obviously the result of an old attack of appendicitis.

The appendix itself was distended and full of a mucoid secretion.

So much for the acute cases. They were all mistakes in the diagnosis of acute appendicitis. Yet I think that you will agree with me that not a single case was made worse by the immediate operation, and some of them, I am sure, were benefited thereby. They all recovered with the exception of the mesenteric thrombosis case. The patient I had to bring out of two cases that had been left for an interval operation, in most of the cases the appendix would have been removed without in the least eradicating the prime cause of the mischief.

It is this thought that always strikes me when, in operating on an interval case, I come across what appears to be a normal appendix.

About a year ago, I removed the appendix in the "cold" from a patient who was said to have had three attacks of appendicitis. My patient left the nursing-home two weeks later, but on the very day she reached home she had another of her attacks. I was called to see her, and the site of the pain made it perfectly obvious that her gall-bladder was at fault. She had never had any jaundice. I operated on the next day, and evacuated a gall-bladder full of stones and pus.

Another class of case which presents difficulty is the condition of tubercular glands about the lower end of the mesentery of the ileum. The glands sometimes reach a large size, and by their periadenitis cause adhesions to form round the end of the ileum and lower end of the cecum. I am sure that this condition very often simulates appendicitis; but the case is usually so mild that it is nearly always operated on in the interval, and then one finds these adherent bands and cascous or calcareous glands as the sole remaining pathology. One has heard a good deal lately of the masses of adhesions about the cecum which have received the name of Jackson's membrane, and the pathological condition of the ileum known as Lane's kink. Though I have never satisfied myself as to the presence of the latter, I have often seen in these interval cases that, although the appendix appears to be normal, yet the whole cecum is large and freely movable though united by lateral bands of adhesions to the outer parietal wall.

This condition may aptly be called the "floppy" cecum. It nearly always occurs in young females, and is generally associated with a history of constipation and attacks of pain in the right iliac fossa, which simulate in a remarkable degree appendix attacks. These, I am sure, form the large part of the cases which are mistaken for appendicitis, and which are operated on in the interval. They get well on purgatives, and are the cases which are so commonly cited in favour of the use of purgatives in this disease. They are the exceptions which prove the rule in appendicitis to give no purgative, for, to use an Irishism, they are not a bad kind of appendicitis at all.

Lastly, I need only mention the mistake of confusing recurrent renal colic due to stone in the ureter with attacks of appendicitis.

Now, the foregoing list of cases sounds somewhat formidable, but, as a matter of fact, they form under 9 per cent. of all the cases. Still, in every ten acute cases there will be one in which the appendix is found not to be the source of the trouble, and I am sure that in the interval cases the percentage where the appendix is removed for some other condition will be found somewhat larger.

In a correspondence lately going on in the British Medical Journal, Mr. Edmund Owen, in a plea for early operation, insists that the case should be seen repeatedly until a diagnosis is made, and then immediate operation should follow. Dr. Ewart, in answer to this, stated that the rule to operate immediately for appendicitis has a strong tendency to become a rule to operate immediately for suspected appendicitis. If he is right, we must face the idea that, to be well, he says, to face that new situation squarely, and to give the subject of suspected appendicitis its diagnosis, and operative conditions the exhaustive consideration which it deserves. Practically, this has been the aim of my paper, and the conclusions which may be drawn from these few somewhat scattered remarks may be summed up in the following:

Every pain in the right iliac fossa does not necessarily mean appendicitis, even when accompanied by the signs usually designated acute abdomen. As Murphy has so succinctly stated, there should be no deaths from appendicitis, yet we are still having them. The reason is, that the deaths are due to procrastination. They are due to waiting for the interval, or they are due to the case remaining a suspected one until it is too late. Operation in the first day or so is no more fatal than the operation in the interval, and I think that it is better to have operated and found a normal appendix during the acute stage than to delay and have a normal appendix in the interval; for in the first case one has a chance of discovering the real cause, but, if one waits until the interval, this chance has been lost, and may render two operations necessary instead of one.

It is not generally appreciated that the operation for the removal of the appendix is easier in the first 24 hours than in the interval, for adhesions may then be troublesome. The really difficult
THE NEED OF PUBLIC LABORATORY CLINICS.

By DAVID WALSH, M.D.,
Senior Physician, Western Skin Hospital, London, W.

By a "laboratory clinic" is meant an institution that combines the work of a clinical laboratory with the actual administration, when necessary, of technical methods of treatment, such as those by vaccines, intra-venous medication, and the like.

The rapid advances of medical science have necessitated the use of many complicated and costly methods of diagnosis. One has only to compare the practice of ten or fifteen years ago with regard, say, to enteric fever, tuberculosis, malaria, and venereal diseases, to realise how vital is the help of an expert pathologist in order to form an accurate diagnosis. Blood examinations are imperative in a large number of cases; sputum must be tested for micro-organisms; and a complicated series of investigations carried out with reference to a host of morbid processes.

The relation of general practice to advanced medical science is well illustrated in the special case of venereal disease, which, above all maladies, demands the services of the clinical laboratory. A great campaign is now on foot to rid the nation of that heavy burden, and a Royal Commission has been appointed to inquire into the subject. As medical men know, many venereal patients come to the special hospitals to have the skin, throat, eye, ear, and nervous system, and to those for women and children. Another large contingent applies to practitioners on the Insurance panel, and to others who treat poor patients. In the majority of cases the real nature of their malady is unsuspected by the patients themselves. Happily, it is now possible in obscure cases to ascertain by means of the Wassermann blood test and other methods of diagnosis whether syphilis is or is not actually present, and whether it has or has not been definitely driven out of the system. Moreover, the prospects of cure have been immensely quickened and aided by the introduction of Ehrlich's famous remedy known as "606," or "salvarsan." Unfortunately, the costs of tests and of remedy is so great as to be almost prohibitive if used extensively in the small hospitals, and still more so among patients of the insured class. A similar observation applies to the bacteriological diagnosis of other maladies, and to the vaccine and other modern remedies needed for many infections of a non-venereal character.

THE COST OF MODERN METHODS.

The increased cost and complexity of modern scientific methods involve serious economic results. They threaten to undermine the whole fabric not only of the smaller voluntary charities but also of the immense field covered by the National Insurance Act, and to a somewhat lesser extent by the Poor Law Medical service. By denying the worker the chance of speedy relief from his illness this modern costliness throws the burden of his support upon the public purse. In many ways it adds to the already heavy problem of how to deal with the waifs and strays of humanity. In the long run, however, it must be met by the provision of modern scientific methods which may be looked on as a sound investment, inasmuch as it lessens the ultimate burden upon the community by its deplorable results. The pressing problem of the moment is how to bring modern medical science to the homes of the poor.

As regards this question of advanced scientific method, existing hospitals may be divided sharply into two classes: first, those that possess well-appointed clinical laboratories, and, secondly, those that are unprovided in that particular way. The latter class are placed in this dilemma: either they must furnish their patients with medical service or else, speaking out the truth, they must be deprived of his purse. Under the last-mentioned conditions it is obvious that physicians would naturally spare the resources of the hospital by limiting the number of investigations, even if no direct pressure were brought to bear upon them by the hospital management. Much the same may be said of the preparation of vaccines and of special methods of treatment.

THE SAVING OF A CENTRAL LABORATORY.

Economically, as I have shown elsewhere, (a) there would be a great saving in the provision of a central laboratory available for a number of small medical charities. To that scheme I would now add the important suggestion that such a laboratory should be thrown open to private and to panel practice.

My scheme aims at the establishment of a central laboratory and clinic, intended primarily to supply the needs of the Metropolis, but capable of wider extension to the provinces later if such a course were desirable. To this institution all voluntary hospitals, panel and non-panel doctors would be enabled to send patients on certain simple conditions for the testing of blood and sputum: for bacteriological diagnosis: and, generally, for all kinds of clinical laboratory investigation. In addition the institute would, at the special request of the medical man concerned, provide and administer vaccines, tuberculin, salvarsan, and other highly specialised and often costly remedial agents.

An immediate result of the establishment of a central laboratory of the kind would be to bring under the best modern treatment a large amount of disease that is now being dealt with more or less ineffectively. Take the case of the panel doctor into whose busy hands drift a large proportion of those patients whose maladies demand laboratory investigation. How, for instance, is he to determine whether a doubtful rash is of tubercular, syphilitic, or other origin? Yet the decision may be vital to the health of the patient, not to mention the friends of the patient and the pockets of the ratepayers. What

a boon it would be to the overworked panel doctor, harassed by many such perplexities in his day's work, were he able to send off his patients to have a diagnosis made or confirmed, to be followed, if necessary, by appropriate treatment! He himself has neither the leisure, nor the special experience, nor the means, nor the appliances for carrying out highly technical and costly modern scientific methods. In the case of the voluntary medical charities the assistance of a central laboratory could hardly be otherwise than valuable. Hospitals are often so crowded, especially in their out-patient departments, that it is impossible to give to individual patients the amount of time and care that is required if scientific justice is to be achieved in each case. In a word, to all medical men who have to see poor patients a central laboratory and clinic such as that under discussion should prove an invaluable aid to the proper performance of his duties.

THE SCHEME IN OUTLINE.

What would be wanted to carry out such a scheme?

First of all, premises would have to be secured in a central situation convenient for the purpose of a laboratory and clinic, the prominent features of which would be:

1. A well-equipped clinical laboratory with various departments, having a staff of expert salaried pathologists.
2. A clinical out-patient department for the administration of vaccines, salvarsan, and other special treatment by a staff of medical assistants.
3. Both the laboratory and the clinical departments would be placed under the charge of a salaried medical superintendent (part-time appointment).
4. The administrative staff would require a secretary, a matron, a nurse, a cook, a wardmaid, and porter.
5. It would be well to have ten to twenty beds available for male and for female patients whom it might be advisable to keep under observation for one night after the administration of certain remedies by intravenous methods.

The cost of the premises and the equipment of the laboratory and of the organisation as a whole would not be great, as things go nowadays; certainly nothing like the vast sums that have been recently lavished upon more than one institution for special treatment, the therapeutic claims of which are still largely of a tentative character. On the other hand, the proposed laboratory and clinic would go straight to the heart of things and would from the first moment of its existence put into the hands of the medical profession the means of dealing with a vast amount of disease in its more insidious forms.

Sooner or later, it may be assumed with a fair amount of conviction, the State will be compelled to furnish some such free laboratory organisation if the principle underlying the National Insurance Act—namely, the supreme necessity of guarding the health of the individual citizen—is to be logically maintained.

For the funds necessary to the carrying out of the scheme I would apply to:

1. The philanthropic public.
2. The small hospitals, which would benefit largely from the laboratory clinic.
3. The King Edward and the other great distributing hospital agencies, inasmuch as the suggested laboratory clinic would (a) lessen the burden on the special and the smaller hospitals, and (b) greatly increase the efficiency of their work.

4. Subsidy from the State on the ground that the efficiency of the panel system would be greatly increased were a central laboratory and clinic available. (It is within the power of the Insurance Commissioners to sanction grants of the kind.)

5. The payment of small fees by institutions sending patients and by panel and non-panel patients on the guarantee of a medical man that the applicant is unable to pay ordinary medical fees, but is in a position to make a small contribution to the payatory clinic. (Indigent persons would, of course, be treated free.)

It may be that amid the conflicting interests which mark the voluntary medical charities of the Metropolis a practical scheme such as that above outlined may not at present find a footing. On the other hand, it may perhaps win approval from one or more of those philanthropists whose generosity appears to be well nigh inexhaustible.

Since the above scheme was outlined in December 1913, its features have been adopted by the Chancellor of the Exchequer in regard to the Insurance Act. In his Budget of 1914 Mr. Lloyd George is providing for the cost of bacteriological, X-ray, and other highly specialised medical treatment for the free use of panel practitioners.

The fact that the State is about to establish free public laboratories does not do away with the need of my scheme. There is plenty of room for a consultative institution for persons who, although not of the insured class, are nevertheless not in a position to employ a consultant and specialist fees. The scheme, in order to bear its fullest fruit, should be connected with a resident hospital in a healthy suburb for the purpose of treating cases which after the fullest scientific investigation are likely to be materially benefited by indoor hospital attention. Any attempt to deal with chronic or hopeless cases would simply detract from the value of the clinic hospital to the curable. In the same way there should be a chronic convalescent home at some secluded place, available for the treatment of cases which after full scientific investigation it is concluded may reap a real benefit from rest and change amid healthy surroundings.

Under present conditions our hospitals and convalescent homes are occupied by many patients who are not likely to receive any lasting and material benefit from their treatment. The clinic is intended to act as a sort of clearing house where the merits of each individual case may be tested, with a view of securing the utmost value from our charitable medical organisations and of throwing open the best modern treatment to those who by lack of system have hitherto had little chance of obtaining sound medical attention and modern treatment in the earlier and curable stages of their maladies. The good that might be effected by a thoroughly equipped clinic is simply inestimable. There would be little difficulty in finding plenty of medical men of the highest skill to help in a scheme, which might be tested by the foundation of a clinic in Central London as soon as there is a prospect of adequate financial support.

PREHISTORIC MAN AND HIS EARLY EFFORTS TO COMBAT DISEASE. (a)

By T. Wilson Parry, M.A., M.D. Cantab.

Ladies and Gentlemen,—The President of the North London Medical and Chirurgical Society stands, I believe, in an almost unique position. His annual address is always delivered at the close, instead of, as is customary in other societies, at the opening of each new session. This somewhat topsy-turvy arrangement of things merits at least one compensation. When the little boy was asked by the registrar, "What were you doing last week?" he simply replied, "Farver never had no last words, Muver always got those."

The president of this Society, not unlike this irresponsible offspring of Mother Eve, is graciously granted the last words, and I wish mine to be those of grateful thanks to you all for the honour you have done me by electing me as your president during the past year.

The subject I wish to introduce to your notice this evening is the relation to the dim and distant past, and is one which, I think, will serve to stimulate the imagination, as well as exercise the more prosaic reasoning faculties. It is always a matter of fascinating interest to delve into anything of a mysterious nature, and the one mystery which, to many thoughtful observers, comes nearest to the obscure and inexplicable origin of Man himself. When and in what form did he first put foot upon this planet, and what was the condition of that planet itself that must have cooled to an extent to have permitted the previous introduction of plant, as well as of animal life. At present all seems impenetrable as to the birth of protoplasmic life and the rise of the human race. Professor Sir Edward Schäfer has given us hints of life being chemically formed. If such, indeed, could be proved, how far should we have progressed on our path towards the Unification of Knowledge. At this present moment, however, we must renounce these philosophical speculations and must transport our thoughts to the more primitive ages, and consider the creation or formation of what we call "life," to that period in unwritten history known to us all as the Stone Age.

Now the Stone Age must be regarded merely as a stage of culture, as every nation and people on emerging from an animal to a human level, however low, starts with its "Stone Age," passes through its "Copper" or "Bronze Age," thence through its "Iron Age," until it eventually arrives at its Historic period, when it begins to depict its acts and its thoughts on stones, pottery, papiri, or coins. The anthropological world is indebted to the late distinguished antiquarian, Lord Avebury, for suggesting the division of the great Stone Age into two parts, namely, the Paleolithic or Old Stone Age and the Neolithic or New Stone Age.

This was no arbitrary division, but a really natural one, and based entirely on geological data. He traced the present geological condition of things back to its source, and this he made his starting-point of the Neolithic Period. In Great Britain and the north-western part of Europe it may be roughly dated as beginning somewhere between twenty and twenty-five thousand years before the Christian Era and lasting till about the year B.C. 2000-1800. It may thus be roughly said to cover a period something like 20,000 years. The Bronze Age succeeded this and lasted till about the year B.C. 800. After this came the Early-Iron Age, which is represented in Britain by the Late Keltic, Early British, or pre-Roman culture.

Immediately preceding the Neolithic Age was a huge gap which cannot well be estimated, but during which geological changes of a gigantic nature were taking place, which constitute the Late Palaeolithic Period. During this transitional period many things were happening, the map of the world was undergoing vast alterations, climates were changing, till, in North-Western Europe, to speak of only one portion of the globe, the dry cold of the later Palaeolithic Period had given place to a more temperate and rather milder type of climate. This change of climate led to extremely important results. While many of the animals that roamed our woods and forests during the Palaeolithic Period were becoming extinct, among which may be enumerated the mammoth, woolly-haired rhinoceros, ursus, cave-dog, cave-bear, and sabre-toothed tiger, others sought summer climes, wandering south—owing to the then unroofed lakes of the prairies, lion, leopard, and hyæna; others again chose to live in a temperate climate and these embrace our present British fauna, together with the bear and the aurochs, both of these latter having been now long extinct in this country.

A third group of animals preferring a cold climate, to which the reindeer, the musk-buck and the arctic bear, the rhino and aurochs, the glacier lads, migrated north or sought the cold mountainous districts of Europe, among these being the musk sheep, glutton, arctic fox, ibex, chamois and reindeer.

And what was happening to Man himself during this long chain of years? In Paleolithic times he was a mere animal, finding his food in the mountains or in the rivers or on the shores of lakes ("River-Drift Man") he was then called) till he overcame his dread of caves which were dark and gloomy and filled with savage monsters or evil spirits and found the protection they afforded more congenial than his previous rough dug-out homes, situated beside streams or rivers and covered probably by branches of trees and leaves, or clay and mud. Having taken to cave-life he began to cultivate Art in a way he had never done before. Although still hunting the mammoth, reindeer and other animals, certain members of his tribe became artists and some of their productions, which we still possess, are of exceptionally high artistic value. We have pictures of the ibex, glutton, wolf, reindeer, mammoth, and other animals drawn on bone, stone and ivory. To two of his carvings I should specially like to draw your attention. One is the conversion of the point of a mammoth tusk into two fletching reindeers. It was originally probably the handle of a dagger made in one piece out of mammoth ivory and a few thousand years before the Christian Era. This was discovered in the rock-shelter ofMontastruc, Bruniquel, France. The other example is the representation of a mammoth itself, carved out of reindeer horn and was also probably the handle of a dagger. This also hails from Bruniquel. The treasures unearthed in the caves of the Dordogne and other places in France give us an insight into the mind and character of the Caveman. By the skilful way he shaped many of his implements, by the thoughtful manner in which he fashioned his bone needles, awls, sceptrs and ornaments for personal adornment, he was evidently a man of high average intelligence. What is our surprise, then, that we, at a much more advanced stage of culture, should suddenly disappear. But such is the case. Caveman in France and the British Isles either became extinct or followed the reindeer to
the far north, and his descendants may be living in those arctic regions today as the race we recognize as the Esquimaux.

Neolithic Man was of a different type to his predecessor. He was not a hunter in the same sense as was Palaeolithic Man. I think he may best be described as a farmer, a builder and a surgeon; at least two of these three, the greatest of his occupations, have been handed down to us. I do not say that individually every Neolithic Man possessed these three accomplishments, for it was possible there were specialists even in those golden days. It is, however, quite within the bounds of probability that a versatile Neolithic Man sowed his cereals on the Monday; hunted on the Tuesday; helped (with lever, fulcrum and mother earth) to raise a ponderous stone of some forty or more tons, and fishered on the Wednesday; flaked flakes or hafted polished stone hatchets on the Thursday; fished on the Friday with bone or shell fish-hooks or speared fish with barbed bone-pointed javelins; trephined an unfortunate friend who suffered from fits on the Saturday, and on Sunday gave up his time to worshipping the glorious God of the Sun, who gave him light and warmth and ripened his corn to a golden harvest. Like the wise men of old he came from the East, probably bringing with him animals he had already domesticated, and we can follow his trail all along the north coast of the Mediterranean Sea by the dolmens and cromlechs he has left behind him. He was no modern pretender, but had a genealogy of proud dimensions, for dolmens have been found on the site of ancient Nineveh. And here I may not done altogether from altruistic principles, but because he felt that, if his dead friend were happy and comfortable, he himself would be less likely to be molested by his spirit. The Neolithic Period is divided into three parts: (a) The Campigyn Period; (b) The Robenhausen Period; and (c) The Carnac Period. It is this last period, the Carnac Period, that will specially interest us tonight, as we have absolute and certain proof that during this period the surgical operation of trephining was performed.

The above sketches of Palaeolithic and Neolithic Man have been given in order to demonstrate that these prehistoric personages were by no means lacking in brains, the former exhibiting specimens of true genius in Art, while the latter produced builders and surgeons of indefatigable and accomplished talent.
To begin at anything like a beginning we must
hark back to times much more remote than these,
to pre-palaeolithic times, indeed, when palaeolithic
man would be looked upon by us as a cultured
gentleman in comparison with those first primeval
savages. In those very early days Medicine and
Surgery were somewhat different to what they are
today. Man was then little above the lower
animals. His instincts were, therefore, akin to
their instincts, and under the same circumstances
he would act similarly, only rather more intelli-
gently. The picture that I have of the earliest
primitive man, at present, is an admixture of Pithe-
canthropus Erectus and the Piltdown woman.
With the former man we are only little above the lower
anthropoid. We see in Simian lower maxilla and canine
tooth we are getting dangerously near our cousins, the
anthropoid apes. A large male gorilla may have a
capacity of 600 c.c., and there would, therefore,
be much less distance between him and "the fossil
man of Java," than exists between this latter and
an average modern European cranium. I need not
enter into the controversy as to whether these fossil-
ized human crania belong to the Early Pleistocene
or late Pliocene Period. The geologist has strong
inclinations towards the former, while the anthrop-
ologist has much to say on the latter. Indeed,
the very mention of the word "cokith" in a mixed
gathering of these two distinguished classes of
savages, if it is not held up to ridicule, will entitle
the golden apple of Eris in an otherwise polite
and agreeable assembly. I have great faith in
what Browning says, "The best is yet to be," and
feel that there are still to be unearthed anatomical
surprises of unparalleled importance which, when
discovered, will necessitate a constant re-arrange-
ment of ideas as fresh material is brought to light.

Now it is well known that animals, like man, seek
solace in the misfortunes of man. When they meet with an
accident or are stricken with a malady, they
eavour to cure themselves. Let me give a few
instances, some borrowed from fact, others from
fable, in order to show not only what authentic
experience has to say, but also what many of the
ancients attributed to the mental processes of the
lower animals. Damage, it is said, which is inflicted,
will cure grasses that have a medicinal action usually
of an emetic or purgative nature. (1) The fibrous
rooted wheat-grass, Tritium Caninum, is fre-
quently eaten by the former. If an animal is ill it
seeks out a dark place and starves itself, taking
nothing but water. This often is all that is re-
quired, as it combines mental and physical restraint
and a good wash out of all toxic substances. If an
animal has been injured, it is noticed to continually
lick the affected part, which is a somewhat crude
combination of our modern fomentation and
massage. Prehistoric Man would most certainly have
licked his wounds. Later when he had lost some of
his earliest animal instincts he probably observed
what the former did, and thus the use of (2) helbore was believed to have been dis-
covered from the goat. (3) Virgil tells us that
dittany was "eaten by wild goats when they were
shot with darts." Pliny gives us one of those
delightful fables referred to above, namely, that
bleeding was taught man by the hippopotamus.
These are his words: (4) "That an intelligent man,
finding himself plethoric, goes out on the banks of
the Nile, and there searches about for a sharp-
pointed reed, which he runs into a vein in his leg,
and having thus got rid of a sufficient amount of
blood, closes the wound with clay. Buffaloes,
horses and camels are exceedingly fond of licking
salt. Prezevalsky says, "On the Mongolian camels,

ally if they have been long without it. Livingstone
says that the chimpanzee, solto, or other anthropoid
apes will staunch bleeding wounds by means of
their finger or of leaves, turf, or grass stuffed into
them. And now we once more resort to fiction.
(5) Cornelius Aprippa tells us that "The sick mag-
pie puts a bay-leaf into her nest and is recovered.
When the lion, if he is feverish, is recovered by the
eating of an ape. By eating the herb dittany, a
wounded stag expels the dart out of his body.
Cranes medicine themselves with bulrushes, leop-
dars with wolf's bane, boars with ivy; for between
such plants and animals there is an occult friend-
ship." Among birds the snake and an animal
particularly in India. (6) Fatig before the Great
Surgical Society of Geneva the case of a snipe who
with his beak and feathers makes a dressing,
applies plaster to bleeding wounds, and even binds
broken limbs with strong ligatures. M. Magnin
corroborated this in the case of a snipe which he
observed fly away with a broken limb, and later
found with the fragments of the limb forming in a
parallel position and undissected by a splint made
of intermingled feathers and moss and bound round
the limb, in a spiral form, by a flat-leaved grass
and fixed by means of a sort of glue. (4) With-
ington reminds us that a number of these stories
that seem improbable must not be entirely refuted,
and he cited the fact that Count Mauclerie, in
the last eighty years, declared that he had
secured in a certain case, a broken leg, by
observing the plants eaten by a mangy dog in the
Appennines. So much for what animals and
birds do for themselves when confronted with illness
or injury. Primitive man did likewise, only always
a little more. Now comes the great separation
when Man stepped away from beasts and birds
and began to think for himself. Originally he may
be thought to have started his development of his
imagination. And here I may remind you that imagination is one of those
forces that, if directed on right lines, is the very
impetus that is essential for progress in both
Science and Art, and is the true basis of originality
and even of genius itself, while, on the other
hand, if allowed to run as a confused course will pro-
duce an over-anxiety of conflicting ideas with
delusions of a detrimental or even dangerous
character.

At this moment we must pass, and not irrele-
vantly, to the history of medicine. This has
been divided into three great parts by two important
landmarks, and these landmarks correspond with
the lives of two illustrious men. The first of these
was a Greek who was born in the year B.C. 460,
and was no other than he who had been distin-
guished by the title "The Father of Medicine." I
refer, of course, to Hippocrates. The second, no
less eminent, was, I am proud to think, an English-
man, and his name is household word among all
scientists, the name of William Harvey. These
two form the stage for the commencements of two great
epochs in medicine and divide the history of
medicine into three prominent parts—namely:
(1) The period from the earliest primitive
times to the coming of Hippocrates;
(2) from Hippocrates to the coming of Harvey;
and (3) from Harvey to our own days. To-
night we are only concerned with the first period
of this division, but it is necessary to point out that
Hippocrates entirely altered the whole system of
medicine, transforming it from a bewildering chaos
of superstitious and frenzied fancies to a definite
science which had for its aim the careful collection
of symptoms of diseases, the courses they ran and
the best treatment that could be applied. No
wonder the name of Hippocrates stands out as a
shining light in a time of darkness and superstition, when truth itself was at an amazing discount. I said just now that it was the imagination of man that first led him to think wrongly, and I will explain this by saying that the first period in the History of Medicine is known as the Instinctive Period, or the Period of Demonology. It might equally well have been called the Experimental Period, for was it not during this time that Man was making his first tests—and during tests many of them must have been—to discriminate between various leaves, roots, berries, fruits and fungi to ascertain their dietary and medicinal values? Now I wish to state here that as embryology epitomises

Fig. 2.—Flint-pointed box-drill used in first stage of trephining skull for removal of rondel of bone.

evolution, so the study of the present-day primitive savage unfolds to us the larger history of prehistoric man. It was no doubt the twin mystery of Disease and Death that first stimulated man to think, that is why the Medicine-man and the Priest were one and the same individual at the outset. The position of the Medicine-man in the tribe must have been a most exalted one. In a fascinating book just published on the American-Indian called (6) "The Vanishing Race," this is well shown. "The Indian," it says, "aspires to be a great hunter; he seeks fame as a noble warrior, he struggles for the eagle feathers of distinction, but his greatest longing is to become a Medicine-man and know the Great Mystery." Witchcraft and magic early took a chief part in the treatment of disease, and Demonology reigned supreme for many millenniums. Demonology is based on "Animism," and this latter briefly consists in the belief in the influence of the spirits of dead persons. Animism has its beautiful as well as its hideous aspect. The wide belief among savage races that inanimate objects, as well as animate beings, are all possessed of a spirit has been well demonstrated lately by Maeterlinck's exquisite allegory "The Blue Bird," which shows the happy side of this creed. The unhappy side is illustrated by the reverence bestowed on spiritual monsters and the propitiation required of them. Can we afford to smile at such beliefs? Was not the God of the Hebrews on many occasions regarded as a demon of unparalleled dimensions, to wit (6) "The Lord shall laugh at him, for he seeth that his day is coming"? The three chief theories of disease were: (a) The anger of a disaffected spirit; (b) witchcraft; or (c) offended spirits of dead persons. The Manirata, a low race of the Malay Peninsula, believe that there is a separate disease-spirit for every illness (this is not unlike our present germ theory), one for small-pox, one for inflammation of the hands and feet, and one for hemorrhage; in the latter case the spirit is thought to fasten itself on the wound of the individual and suck out his blood. In the Indian Archipelago disease-spirits are conciliated by presents and dances. (9) In Polynesia every illness is set down to deities which have been offended or which have been urged to afflict the sufferer by their enemies. (9) The Prairie Indians treat all diseases in the same way, as they must all have been caused by one evil spirit. (9) The aboriginal New Zealanders had a separate demon for each part of the body to cause disease. Tonga caused headache and sickness; Moko-Tiki was responsible for chest pains, and so on. The Zulus believe that spirits, when angry, seize a living man's body and inflict disease and death, and when kindly disposed give health and cattle. (9) The Dayaks of Borneo acknowledge a supreme God, but attribute all kinds of diseases and calamities to the malignity of evil spirits. Their system of medicine consists in the application of appropriate charms or the offering of conciliatory sacrifices. Verily the whole world is kin, for we have only to step across the channel into Brittany to-day, to find that similar pagan ideas are still universally accepted there, but, of course, under very different auspices. The Briton's deities are neither Tonga nor Moko-Tiki, but if they are suffering from boils they offer prayers to St. Maudez, if from fevers
the XVth century the Catholic Church had a very
long list of saints, each of which presided over
some special complaint. St. Agatha healed sore
breasts, St. Apollonia toothache, St. Benedict stone,
St. Blaise quinsy and hemorrhages sticking in the
throat, St. Erasmus colic, and so on indefinitely.

OPERATING THEATRES.
KING'S COLLEGE HOSPITAL.
Amputation of Limb.—Arthur Edmunds operated on a man, at about 30, who had
been admitted with the following history. The patient had always been a well-conducted, quiet, and indifferent
person in regular employment, with no personal worries except some slight disability on
examination two or three times, and was expecting to hear the
result of a further attempt. He had retired to his room,
changed his clothes, but he remained for so long a
time that his father knocked at his door to see if he
had fallen asleep. On answering, the father insisted on being admitted, when he
found that the room was dark and heard his son utter
a groan and fall back on the bed. A light was fetched,
and it was found that the patient's right hand was
almost entirely useless. The police were sum-
mmoned, and a small penknife with which the injury
had probably been inflicted was found in the bed.
A temporary tourniquet was applied and the patient
removed to the hospital. On admission he was found
to be suffering severely from shock and loss of blood.
On examining the hand, there was a deep incision
about an inch above the wrist joint, dividing all the
superficial tendons and other structures down to the
bone, actually tearing into the promotor quadratus.
On the back of the wrist were two small stab wounds
perforating the joint, as if the patient had endeavoured
to locate the articulation with the point of the knife.
Opposite to these punctures on the front of the wrist
was found another division of the distal part of the
tendon, opening the articulation and leaving the hand
connected with the arm merely by the skin and the
extensor tendons. This remarkable accident was self-
inflicted, the patient's expression being that "he
had been having a go at himself." Hemorrhage had
stopped to a great extent, and the problem which
presented itself, Mr. Edmunds remarked, was whether
it would be possible to save the hand, or whether
4 would be wiser to amputate straight away. The latter
course was decided upon for several reasons. In
the first place it was very doubtful whether the tag of skin
would contain sufficient vascular supply to prevent
gangrene; in the second place, any attempt to restore the
tendons and extensor" was a mere dream, for neither
of which had been severed in two places, would
have required an operation so prolonged as to have been almost certainly fatal: besides it
was not clear whether under any conditions a useful hand could be restored. Mr. Edmunds had pointed out that it was tempting to adopt an expectant attitude
to see how far the circulation would become restored
and to allow the patient's general condition to improve;
but such a course would be accomplished by a risk of
sepsis in a lacerated wound through avascular tissues.
It was therefore considered advisable to perform an
aseptic operation through the forearm just above the
upper end. This was done by equal flaps with a
circular division of the skin. The wound healed kindly, and the patient's
pulse and general condition rapidly improved after
an intravenous saline injection. Forty-eight
hours after the operation the patient seemed quite con-
tented, and referred to his mutilation complacency
with apparently no realisation of the disability which
the loss of his right hand would entail. A few days
later he seemed to lose all memory of the incident
except as if it had occurred 10 years before, and no time was he
able to give any reason for his act, nor was it possible by
questioning his relatives to obtain any clue as to
the reason for his extraordinary self-mutilation.

Mutilation of the genital organs, Mr. Edmunds said,
was not uncommon among the lower classes, and
with morbidly exaggerated remorse for some lapse of
chastity, but for a normally right-handed man to hack
off his right hand with a small penknife was a problem
for which it was difficult to find an explanation.

TRANSACTIONS OF SOCIETIES.
EDINBURGH MEDICO-CHIRURGICAL SOCIETY.
Meeting Held July 1st, 1914.
The President, Dr. John Playfair, in the Chair.
A committee which had been appointed at a pre-
vious meeting to consider
Quarantine and Infectious Periods,
submitted the following report:
I.—(a) That certain of the common infectious
diseases—viz., chickenpox, rubella, and mumps,
being of such slight importance from the points of
view of morbidity and mortality that no serious
advantage be ignored as far as quarantine is concerned,
the actual patients themselves being of course at once isolated.
(b) This is not meant to apply to contacts
including school children, hospitals proposing to
return to a school which is free from infection.
(c) As for all practical purposes the above-named
diseases do not occur twice in the same patient, where,
in the case of patients over seven years of age, there is
evidence that the contact period has suffered from a pre-
vious attack, the above rider (b) does not hold.
(d) As the use of the term "German measles" leads to a
serious confusion in carrying out regulations for both
"measles" and "German measles," it is strongly
recommended that the name "rubella" be substituted
for that of "German measles.
(e) In the case of a patient contracting any of the above diseases,
the isolation period is as follows:—(1) Chickenpox,
when every scab has fallen off; (2) rubella, in five
days after the eruption of the first rash; (3) mumps, in
not less than a fortnight from the date of onset, and
in not less than one week after the subsidence of all
swelling in the neck or elsewhere. (f) In the case of
contacts who have not had previous attacks, the
following are the isolation periods:—(1) Chickenpox,
in three weeks from the last exposure; (2) rubella, in
three weeks from the last exposure; (3) mumps, in 25
days from the last exposure.

II.—Whooping-cough.—The spread
of these two diseases is largely due to the fact that they
are most infectious before they can be diagnosed; still,
in view of their serious character, isolation of actual
cases and of "suspects" should of course be promptly
carried out. Chickenpox is not an infectious
infectious disease is not to return to school for at least three
weeks from the date of the appearance of the rash.
In the case of "contacts" who have not had the disease
the period of quarantine should not be less than 12
days. Chickenpox is not a communicable disease. A
previous attack may return to school if the patient has
been isolated, and efficient disinfection of the contact has
been carried out. (This recommendation is subject to
modification in the small schools of houses.) Whoop-
ing-cough.—It appears most probable that the infec-
tivity of whooping-cough is associated with the
catatrophic stage, and in the absence of complications
appears very shortly after the development of the
"whoop." It is desirable that, in a patient's own
name that he be under careful treatment or observa-

CORRESPONDENCE.

July 8, 1914.

The Medical Press.

III.—Diphtheria.—A patient contracting the disease must be isolated until the condition of the throat, nose, ears, etc., is normal, and until at least two consecutive negative swabs, taken at intervals of 24 hours, have been obtained from the affected parts. "Contacts" should be kept under supervision until two negative swabs have been obtained at intervals of not less than 24 hours.

IV.—Typhoid Fever.—A patient contracting the disease must return to school in not less than six weeks from the onset, and after complete recovery. No quarantine of "contacts" is required except in special circumstances.

V.—Scarlet Fever.—Patients contracting the disease must be isolated for not less than six weeks from the date of the eruption, and until recovery from all complications, which may have a distinct bearing on the question of infectivity. "Contacts" must observe a quarantine of not less than ten days after efficient disinfection. It being generally agreed that the incubation period of scarlet fever does not in any case exceed five days, the Committee (with one exception, Dr. Maxwell Williamson, who of opinion that "contacts" should return to school in seven days.)

Dr. C. B. Ker thought the report was an advance as regards the more trivial infections. He still believed that five weeks' hospital detention was sufficient in scarlet fever.

A long quotations just made the patient's "carrier" of the disease. Desquamation had nothing to do with infectivity.

The report was adopted.

The report of a committee appointed at a previous meeting to consider the

RELATION OF THE MILK SUPPLY TO THE PREVALENCE OF TUBERCULOSIS

in the City was submitted. The conclusions and recommendations of the Committee were as follows:—

Conclusions.—The general conclusion of the Committee after consideration of all the evidence is that infection of children in Edinburgh with the bovine bacillus derived from milk is prevalent. From the absence of data it is impossible to say whether the disease is more common here than in other cities under similar conditions. The Committee is further of opinion that the means taken by the Edinburgh Public Health authorities to secure a non-tuberculous milk supply for Edinburgh are at present insufficient. The Committee believes that at present the only means by which the consumption of milk in Edinburgh can be rendered certainly safe is through its being sterilised by boiling at the hands of the consumer. They are aware that two main objections have been raised to that procedure,—namely, firstly, that thereby the nutritive qualities of the milk are seriously impaired; and, secondly, that the sterilisation process destroys certain qualities of the milk and renders children nourished upon it liable to a form of scurvy. With regard to the first of these, the Committee is of opinion that the objection is groundless. It has arrived at this conclusion from a consideration of the evidence collated by Lane-Claypon (Reports to the Local Government Board on Public Health and Medical Subjects, New Series, No. 63, H.M. Stationery Office, 1912), and from the evidence which has come under the observation of its own members and of others whom it has consulted. With regard to the second objection, the Committee apprehends the position to be as follows. It is very possible that the process of sterilisation, if not wisely carried out, may cause damage to the milk, and if the milk is not made up by mothers or fed exclusively on boiled milk, in a certain small number of cases a degree of scurvy may result, but the condition is a slight one and readily yields to simple treatment given in time. Where children from the time they begin to be nourished on a properly adjusted mixed diet, infantile scurvy is practically unknown. It has been stated that children fed on boiled milk are more liable to rickets than where raw milk is used, but in the opinion of the Committee no evidence exists pointing to such an occurrence. Within recent years the argument has been advanced that it is actually a benefit to a child to be fed on the milk of tuberculous cows when this is mixed with a large quantity of tubercle-free milk, in that the children are thereby immunised against tuberculosis and are less liable to infection with the virulent human strain of the bacilli in later life. In the opinion of the Committee this contention is at present unproved, the opinion advanced, that the bacilli so advanced have largely been of an academic nature. In any case the Committee is of opinion, firstly, that the risk of serious disease being contracted from tuberculous milk must be put against the supposed immunisation effect, and secondly, that it is establiished that the bovine bacillus can immunise an individual against subsequent infection with the human bacillus, there are safer means by which this immunisation can be accomplished than by using living tubercle bacilli given in milk.

Recommendations.—The Committee recommended as follows:—First, that the members of the Medico-Chirurgical Society use every opportunity meantime to urge upon the public the necessity of drinking all milk consumed in their families; secondly, that a strong representation be made to the Town Council with a view to the reorganisation of the administration regarding milk examination and the inspection of cows, and thirdly, that Government be urged to carry through at an early date a Milk Bill along the lines of the Bills which have been under the consideration of Parliament in 1912. Prof. Koch's view that bovine tuberculosis was non-infective to man was now exploded. The idea that a moderate infection by bovine tuberculosis might be salutary as a preventative of human infection had no scientific basis. It was the duty of the Government to press this on attack, or at least not to encourage any such idea.

Mr. Stiles said that he was in the habit of tracing the milk history of cases of tuberculosis in children, and that of the cases of bovine infection coming forward.

He would allow adults to drink tuberculous milk at their own risk if they were so minded, but infants ought to be protected. The larger towns should appoint bacteriologists to examine milk coming from the country. The rural households would have difficulty in their bacteriological work done free, but they would have every inducement to see that their milk was free from infection.

The report was adopted.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, July 4th, 1914.

At the Congress for Surgery, Herren Meyer and Magnus Marburg, reported on some experiments they had made on the

SURGERY OF THE KNEE JOINT.

The object was to learn what were the conditions under which mobilisation was resisted by tissues that had become ankylosed. With this in view they had opened the joints of rabbits, removed the whole of the cartilage replacing it with other tissues, muscle or fascia, placing those substances between the ends of the bones forming the joint, or in other cases leaving the joints without further treatment than the simple removal of the cartilage. The surprising result of the experiments was that in every case the joint was still movable after recovery had taken place, whether the ends of the bones or not. The fact was that the ends of all the bones implicated became covered with a fibrous cicatricial tissue. In the cases in which muscular tissue was inserted the fibrous tissue was formed of degenerated muscle, and when nothing was inserted the replaced tissue was granulation tissue that had
developed at the ends of both bones. The essential thing was the isolation of any part removed by the operation, and prevention of the development of free bodies in the joint; the flaps of fascia acted best, however, on the blood poured into the joint at the operation. The technique was not the same for all the joints. In the knee joint the patella was partly removed by operation and the operation laid in a bed of fat. At the reconstruction a tenon of the peroneus enveloped in fascia was made use of for extension. The Kirschner's pin was not always in use now on account of the danger of its softening, but the operation was performed through two lateral incisions. In order to prevent lateral movement a wide groove was made for the patella, and extension tendon by chipping off the anterior surface of the condyle. At the hip joint there was no chisel followed by insertion of fascia or osteotomy at the neck of the femur with formation of a saddle joint with a view of providing for movement in two directions.

At the elbow joint the triceps and ulna were covered with a mantle of fascia. At both the finger and wrist joints the fascial tissue was made use of.

The further fate of neartubes was studied by careful examination. In arthritis deformans developed, nor any serious secondary deformity. The thick covering of the ends of the joints resembled that of the tendon sheaths. The newly-formed cavity was to be looked on as a serious cavity which developed in spite of the most extensive extirpation of the capsule. The free joint bodies which were not covered with cartilage showed no change in either size or form. This also showed the role of the cartilage in regards to adaptability to function of the newly-formed machine. The deep sensibility and the reflexes were completely retained. They, in fact, satisfied the highest requirements.

The indications for such operations had undergone some restrictions since Payr had had unpleasant experience in a case of joint tuberculosis.

The speaker then brought forward four cases; one of tuberculous of the knee, two cases of neartubes of the knee, and one of epiphysitis of the intra-phalangeal joint. In all the cases mortality was sufficient for the requirements, while the mechanism proved itself reliable. During the last two years the speaker claimed for the case of tuberculous joint to function in stiff joints with five failures. The condition of the joint in the case that had been operated on the longest—four years—was excellent and permanent.

In the discussion that followed, M. Hesse, St. Petersburg, said that in injury to both crucial ligaments he had replaced them with free fascia with good result. M. Hochholz had good results in five cases of injury to the elbow. Dr. Röpke Harnbem had more good results with bad embolism into injured joints. The customary indications were to be observed, but it had been shown that even with long existing inflammations and fistula into the joints success could be obtained after resection and embolism of fat into the joint. Recently he had made use of free transplanted fat flaps for filling up defects after extirpation of a meniscus in the knee joint, as a substitute for the bone lost and in the treatment of congenital dislocation of the hip.

He had operated also in cases of tuberculous disease of several joints. In cases in which there were old fat flaps, longer lasting results were obtained. Fat flaps of fat had healed in without the least trouble. The incisions were so made that the muscles were as little interfered with as possible. It was an object to operate with as perfect arrest of hemorrhage as practicable and the great disadvantage of the local immobilising dressing remained on about three weeks especially over the larger joints. The treatment in tuberculous cases was the same as in others. Treatment had not been so successful in the knee joint cases as in the elbow. The one occurring in the knee joint, and fistula in consequence of non-healing in one fistula, there was a partial casting off of one of the fat flaps, where, however, the motility of the joint was not much interfered with. In some cases the range of movement of the joint had minimised the result as the resection of the condyles had not been sufficient that for the haemorrhage it would have been enough. In that a comparatively wide circumscribed recurrence in the skin, but recovered without sequelae. In both of the cases, however, the patella remained free over the bolstering up with fat. This was important as regarded retention of the function of the extensor muscles. The later operation for mobilisation had then a better chance of success.

AUSTRIA.

Vienna, July 4th, 1914

TENTH CONGRESS OF THE DEUTSCHE RÖNTGEN-GESELLSCHAFT.

PROF. PAUL KRAUSE (Bonn), President, presented the report of the Committee on

THE BIOLOGICAL INFLUENCE OF THE RÖNTGEN RAYS ON THE MOVEMENTS OF ANIMALS AND MAN.

This report opened with a dissertation on the influence of the Röntgen-rays on bacteria isolated on agar. Both had been found to remain unaffected by the rays, or affected to a merely unsubstantial degree. Neither in test-tube nor in living tissues was any noteworthy influence observed. Ferments were no more affected by exposure to the rays than to other organic structures. Small living animals were killed by the Röntgen-rays; in case of mice, the lethal dose ranged between 20 and 30 r. Experiments on animals will perhaps furnish data for a judicious regulation of the dosage. The fluids and secretions of the human organism were not affected when exposed to the rays in test-tubes. But these exercised a rather considerable influence on the lymphoid tissues, on the bone-marrow, and on the lymph-follicles of the walls of the alimentary canal. The degenerated thymus gland was found to take on a regenerative growth under the influence of moderate doses; when large doses were administered it was completely destroyed. The following effects were noted and classified:

Blood: at first, hyperleucocytosis; afterwards, hypoleucocytosis. Eyes: where the eye was considerably affected, tendency to formation of cataract under exposure was especially noticeable in case of young animals. Nervous system: in young animals, there was a decided tendency to form a Röntgen-ray effect; not in case of old ones. This tendency in young animals was by some observers seen to be influenced. Such influence was not, however, noticeable in the cases observed by Krause. The liver displays but little radiosensitivity; the kidneys just as little. In the growing stage the mammary gland showed the same, so is the thyroid; neither is so after completion of its development, in any of the animals experimented on. The lungs, bones, and cartilages display little radiosensitivity. Krause had repeated the experiments which had been made in the United States and had constructed large tables of results, which included both his own and those that had been obtained by others. The skin displays dermatitis of the first, second, and third degrees; at later periods secondary changes appear, in the form of Röntgen carcinoma. In one case scleroderma was observed to occur. The condition of the blood is very amenable to the influence of the rays. The first manifestation of their influence appears in the form of a hyperleucocytosis; this is followed by a decreased proportion of leucocytes present. The presence of leucocytes is not clearly demonstrable. With regard to the eyes, a stimulating effect on the conjunctiva, cornea and choroid was always observed. A tendency to the formation of a drop-like opacification of the surface of the lens was also noticed. Children under the age of three must be warned off from the Röntgen-rays, but they
are not injuriously affected by the degree of exposure necessary for diagnostic purposes. The peripheral nerves are not injuriously affected. The President, in degenerative the theories which had been offered in explanation of the influence of the rays on the skin. According to some authorities, the cells were directly affected, especially the young and vigorously proliferating ones. According to others, the destruction is attributed to the photodynamic effects, the lecithin hypothesis, and the destructive action of the ferments. In summarising, he reproduced a table from Wetterer, in which the respective degrees of sensibility of healthy and pathological tissues to the action of the rays were placed in order according to the reports of the various observers. And we find that their effects are so graduated that small quantities stimulate, while moderate dosage restrains, and large doses kill.

The Influence of the Röntgen Rays on the Ovary.

Dr. Reifferscheid (Bonn), Vice-president, then read a communication on "The influence of the Röntgen-rays on the ovary in the animal and in the human organism." The author had carried out extensive experimental and histological investigations in this department, which he had arranged and carried out on the white mouse. He demonstrated the fact that in this animal grave degenerative processes were produced in the ovary by exposure to the Röntgen-rays, which are manifested in grades varying from the degeneration of the epithelium of the follicles to complete dissolution of the same, and to destruction of the ova themselves. Under the influence of large doses even the stroma was greatly injured. In case of larger animals, it was also found that corresponding degenerative processes were brought about in apes and dogs, for example. The similarity of histological structure tends indeed to lead us to anticipate that corresponding conditions will inevitably cause the production of similar alterations in the human body. And in fact the experiments which had been carried out by the author on the condition in which he had applied to seven human ovaries, with a dosage of from 5 to 30 vistas, demonstrated the fact that degeneration of the follicular epithelium and the ova resulted in the same way from the action of the rays. Thus, a positive histological foundation for the therapeutic employment of Röntgen-rays in gynaecology was proved to exist. In addition, the occurrence of haemorrhages of greater or less extent was always noticed in the ovary which had been experimented on; these haemorrhages in general were not marked, but in specific cases the blood was found to have a larger collection and which had always found, in every one of a great number of experiments which he made on the living ovary in various animals, that no regeneration of the ovarian structures which had been injured by exposure to the Röntgen-radiation was ever attempted, which he had observed after doses which had once been destroyed could never be restored. The only example of regeneration observed has been of a vicarious form; when the neighbouring follicles that had nearly reached maturity had been destroyed, while the approximation of the stage of ripeness remained unimpaired, one of the latter was found to attain maturity after the lapse of some time. This communication was illustrated by many microscopic sections, of which the figures were projected on the screen.

The Biological Effects of the Röntgen Rays.

Dr. Simmonds (Hamburg), Vice-president, made a communication on "The Biological effects of the Röntgen-rays on the Testicles." Here the influence of the rays was manifested solely by their effects on the spermatoblasts—the other cells all remaining unaffected. After having passed through a latent stage of two or three weeks, the spermatoblasts break down, and the seminal tubes are filled with masses of debris only. Functional repair is possible through proliferation of the spermatoblasts which have escaped destructive injury; this fact was proved by experiences derived from observation on men and animals, who had been experimentally injured by exposure to the rays.

Hand in hand with the disappearance of the spermatoblasts appeared the active proliferation of the intermediate cells, while the fact that the latter carry out the function of production from the internal secretion is proved by the unabridged retention of sexual desire and of other sexual characteristics, even after the complete disappearance of the spermatoblasts. The Röntgen-rays annihilate procreative power, but not manhood. This communication was illustrated with a series of extremely beautiful microscopic slides projected on the screen.

Dr. Körncke (Poznań-Poldersdorf), Vice-president, then brought forward a communication on "The Biological Effects of the Röntgen-rays on Plants." This communicate vindicated the view that the influence of the Röntgen-rays on the most diverse forms of the vital activities of plants, and discussed in this connection the exhaustive photographic investigations which have been made, partly by the author himself, of the influence of the rays on manifestations of movement, circulation of plasma, turgescence, assimilation, formation of chlorophyll, cell multiplication and nuclear division. The net result derived from the whole of these experimental observations may be briefly summarised as follows: the germination of the seed is often promoted, and to a striking degree, by exposure to powerful Röntgen-rays, while, on the other hand, the corresponding rays have a distinctly retarding effect on growth—which retardation comes to be most manifest only after the lapse of some time subsequent to the radiation. The range of this interval depends on the object tested by the experiment, and on its physiological condition at the exact period of exposure to the rays. With moderate intensity of radiation, the retardation of growth was found to be merely transitory; while small quantities of the rays had the effect of promoting growth. No marked difference could be made out between the respective actions of the "hard" and "soft" rays. The various species of plants, and even the different individuals of the same species presented differences in their degrees of radio-sensibility. Up to the present, no practical application of the results obtained in this way to the objects of agriculture, could be said to have been definitely reached.

II.—Diagnostic Application.—Thorax and Abdomen.

Note.—Report of committee and discussion will be given in our next issue.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Dr. W. E. Carnegie Dickson,
Pathologist to the Edinburgh Sick Children's Hospital, has been appointed Director of the Pathological Laboratory, Royal Hospital for Disease of the Chest, City Road, London. Dickson was Lecturer on Bacteriology in the University of Edinburgh for a number of years, and on the appointment of Professor Robert Keith, the Chair of Bacteriology was converted into one of applied bacteriology, which Dr. Dickson now holds. He has been a most successful teacher, and has done a great deal of original research in connection with the study of the blood and on bacteriological subjects; he is the joint author of a standard work on pathology, and has recently written an excellent small manual on bacteriology.

The National Insurance Act in Scotland.

The administration of the Drug Fund formed the subject of a most excellently contributed article in the Scotsman of June 30th. The writer regards the Drug Fund as the most vulnerable point in the panel system. He points out that in the early days of the Act it was believed that 1s. 6d. would be more than enough to meet demands, and that for this reason
many doctors did not practise economy in prescribing. This
however, has been falsified, much as reports from several Insurance Committees for the first quarter of 1914 show that not only has the Drug Fund been exceeded, but the “floating sixpences” (Drug
Subvention Fund for instances), and the chemists’ bills will have to be discounted. This is due to the action
on the panel system, and the responsibility of checking it lies with the doctors and chemists, who
are the expert advisers of Insurance Committees, and hence in the hands of the Fund. Chemists’
committees can not only check improper items in
chemists’ accounts, but report on extravagant pres-cribing. It is, however, the fact that in some areas
two chemists are employed, that is, that in some parts to that we would have a salutary effect in this respect. It is highly probable that those who would stop using proprietary preparations, which are expensive for which satisfactory pharmaceutical substitutes exist, and also probably stop the prescribing of drugs which remain in the pharmacopoeia mainly as relics of past empiricism, there would be enough money for standardised modern drugs, something which has been long advocated. On the other hand, those who have had to forgo repeats would have to be considered.
In the opinion of the writer of the article, this question of prescribing must be seriously taken up by the doctors’ and chemists’ committees if they wish to prevent the reinstallation of the Approved Societies in place of, or to transmute the panel system, in itself a compromise, into a State Medical Service.
From the second annual report on the Insurance Act, issued the other day, it seems that in Scotland
the number of exempt persons is very few—not more than 5,000. The most important case of exemption is that of the share farming communities, which provide a savings scheme for their own members. In this respect, the number of exempt persons is very few, but the number of exempt persons is very few, and they have had an exceptionally light sickness experience. Only 50 per cent. of their claims were paid in full, owing to lack of funds at the contributors’ credit. The number of deposit contributors does not tend to increase. There has been during the year a movement towards absorption of small societies in large ones, which, actuarially, is in the right direction. As regards
Insurance Committees, in smaller areas the funds for administrative purposes are provided, and the Cod
mission are considering supplementing these. The magnitude of the work of collecting 12 million funds is obvious: it has been lessened by changing the duration of the members from 1 year to 2, so that there are nearly 23,000 lost cards, or 70,000, lying with the Commissioners, in spite of every possible step being taken to secure their return to their owners.
A curious deal has been heard during the year about sickness certificates. The matter has now been simplified by the adoption of a uniform form. The Commissions are advised that a doctor acting in good faith were not responsible for the action for damages for specifying the patient’s disease on a certificate. The cost of medical referees is to be borne on societies’ administration funds. As regards maternity benefits, doctors’ and midwives’ fees have increased over the work, but, of course, not on the scale, and any attendance given is better than before the Act. There is also an increase in the number of confinements attended by doctors, and a decrease of from 15 to 35 per cent., in the case of attendance at maternity hospitals. Cases of mis-spending on medical benefits have been very rare. Medical benefit has worked smoothly on the whole. The introduction of the medical card as a voucher, which was the chief change during the year, is proving a great encouragement to all concerned. The great difficulties presented by the introduction of the new insurance are overcome by the Insurance Committee are referred to. These are in effect the censuses of a constantly fluctuating population, and the expedients for paying the doctors for the two months on the tips which were n chosen doctors are mentioned. It is well known that the present question of the indexes is by far the greatest difficulty that clerks to insurance committees have to contend with. The report contains a number of other points of interest, to which we shall refer next week.

ADVANCE IN THE TREATMENT OF INFECTIOUS DISEASE.
At the farewell dinner given to Dr. John Brownlee
on his leaving Ruchill Hospital to be statistician to the Medical Research Committee in London, there
were present Dr. T. K. Dalziel, Dr. J. C. McVail, Dr. A.
K. Chalmers, Professor T. K. Monro, Mr. A. E. May-
lard and others, the company numbering about 120.
Dr. McVail, in replying to the toast, spoken by the
deputy chairman, Dr. Gibson, Professor of Midwifery
in the University, Dr. Brownlee said that he had been
from 14 years a superintendent of hospitals in Glasgow,
and having a fair acquaintance with the whole of the
modern developments of the science of medicine in
the scientific and administrative work, and treatment, he wished to say a few words in regard to the future of fever hospitals. The next great advance in medicine must come from fever hospitals. The great work of practical physiology of the scientific work which had been done during the last 10 years in medicine had been done from the point of view of infectious disease. He had received every consideration from the Corporation of Glasgow; he had an equipment in which the country had not had before. He had no doubt that the committee in Glasgow would realise that as they must supply laboratories, they also must supply sufficient men.

INCORPORATED GLASGOW DENTAL HOSPITAL.
The annual general meeting of members and sub-
scribers was held on the 30th ult. Among those present were the Dean (Dr. W. C. Anderson), Coun-
cillor Dr. Henry Whitehouse, Dr. Stromer, and Dr. Webster. The total number of operations was 16,058. During the year 27 students joined the Hospital for the full course of two years, and in addition eight for shorter periods, averaging 17 each year. Dr. William Beattie, said the work done at the Hospital was remarkable and the expenditure really small. Ex-Deacon-Convener James Macfarlane was appointed Vice-Preident of the Hospital and Chairman of the Board of Governors.

NATIONAL HISTORY SOCIETY OF GLASGOW.
Although materia medica is threatened with expul-
sion from the medical curriculum, neither botany nor
zoology is seriously menaced. At a meeting of the
National History Society of Glasgow, Mr. James
Stirton, M.D., exhibited some very rare mosses. Among
the species was Amblystegium Juratakanum Sch., which was got in France and the mosses by Mr. Sch.,
and Barbara Oubusula Lindb., from Bridge of Allan, a moss that has not hitherto been found out of certain parts of Sweden. Mr. John R. Lee exhibited
with notes, The Bryhnea, a new record for the Clyde, from Drumchapel: W. Polymorpha Schip., from Ben Naunain; and Trichotonium Tenneostre Lindb. var. Dalhinum De Not., from Glenfalloch. Mr. D. A. Boyd read a paper on "The Botany of the Clyde Waters," giving a number of new records. Mr. John Paterson read a paper on "The New Forest," giving a short account of the main features of the forest, and showing how these affect the plant life, in particular the tree forms, on which so much interesting notes with Glascow. An instructive account of the bird life of the forest was
also given, with many valuable observations on some of the rarer species.

**Ante-Natal Hygiene,**

Dr. A. K. Chalmers, Medical Officer of Health for Glasgow, has been reading a paper at the annual conference, held at Liverpool, of the National Association for the Prevention of Infant Mortality. His subject was "Ante-Natal Hygiene and its Relation to Still and Premature Births in the First Months of Life." In the course of his address he said that from a table relating to Glasgow and dealing with deaths in the first four weeks from several causes per 1,000 births during 1891-1898, it was shown that the principal cause was immaturity. In conclusion, Dr. Chalmers said that Dudley and Ballantyne especially had recently focussed the argument for the registration of still births in a convincing manner, and that until some such movement as that of a national league for the reduction of the mortality from premature births should be instituted, much of the obscurity which surrounded post-natal deaths from immaturity would remain.

**LETTERS TO THE EDITOR.**

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

**IMPERIAL ASPECTS OF THE POPULATION QUESTION.**

To the Editor of The Medical Press and Circular.

Sir,—To those who recognise the full significance of the falling birth-rate as a prime factor in shaping the destiny of our country and our empire, it is satisfactory to notice the increasing attention which it is gaining from statesmen and the Press. Not only the Medical Press and Circular, but also the Times of to-day and the Journal of Philanthropy, have in the last months devoted to the subject far more space than is given to the question of our national defence. The efficiency of the means by which all these evils can be mitigated and speedily put an end to has been proved by experiment. The number of our unemployed can be reduced to a minimum. We need not compel our sailors to go to sea. We might offer a home across the seas to every decent subject for whom a place could not be found in these islands, and we could make the conditions so attractive that multitudes would avail themselves of the opportunity. To do this is no doubt due to economic pressure among some sections of society. For this remedies might be found, and it is to be borne in mind that children are the emigrants most in demand. The fall in our birth-rate is most conspicuous among the classes upon whom the rearing of a large family imposes no real burden. The motive in most of these cases is financial and in France is entirely anti-social and anti-patriotic. It is of a moral disease which, as the French experiment has proved, is fraught with danger to our country and our empire.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rosery,
Earlwood Common.
July 1st, 1914.

**OPEN SPACES AND PUBLIC POLICY.**

To the Editor of The Medical Press and Circular.

Sir,—Discussing the root causes of the evils described by Dr. Fletcher Little in my last letter I wrote as follows: "No people with any feeling for beauty would allow for one day in the very centre of the capital of the Empire the existence of that queer jumble of incongruous caricatures of architecture and art formed by Trafalgar Square. It is interesting to note that the same writer in the Times has, since my letter appeared, expressed the same view. M. Abel Hermant, who has lately visited London, describes Trafalgar Square as "The most frightful place in the world," and the New York Evening Post, I believe, is of a similar opinion. It is really astonishing that so little has been done to improve the square, which is the gateway to Parliament and the West End, and is the first space upon which the eyes of foreigners rest when they arrive at Charing Cross. Why not impose a dignified style of architecture upon the surrounding buildings? The haphazard methods of London builders and the utter indifference of the authorities to any kind of aesthetic Hygiene have surely had their day."

The answer to M. Hermant is that suggested in my letter—the British people at the present day lack the aesthetic sense which is an indispensable attribute of a really civilised race.

I am, Sir, yours truly,

AN ARCHITECT.

July 4th.

Mr. A. Hopewell-Smith, L.R.C.P., M.R.C.S., L.D.S., John Tomes Prizeman of the Royal College of Surgeons of England, and Surgeon and Lecturer on Dental Anatomy and Physiology at the Royal Dental Hospital of London, has been appointed to the Chair of Comparative Odontology and Dental Histology which it has been decided to establish in the University of Pennsylvania at Philadelphia.
OBITUARY.

DR. C. T. VACHELL, OF CARDIFF.

We regret to record the death of Dr. Charles T. Vachell, J.P., the well-known Cardiff physician, who took his place on the staff of the Monmouth Infirmary at Clifton, where he had been undergoing treatment for a chronic malady. The deceased, who was born in 1845, qualified M.R.C.S.Eng., in 1869, and became F.I.C. in 1877. After holding house appointments at King's College Hospital, London, and the Glamorgan and Monmouth Infirmary, he became attached to the medical staff of the Cardiff Infirmary. Dr. Vachell was Consulting Physician to King Edward Hospital, Cardiff, an ex-President of the South Wales Branch of the British Medical Association, President of the Cardiff Naturalists' Society, and Honorary Curator of the National Museum of Wales. He was also formerly a Surg.-Lieut.-Col. of the 2nd Glamorgan Volunteer Artillery. Dr. Vachell took an active part in Welsh educational affairs.

REVIEW OF BOOKS.

AIDS TO MEDICINE. (a)

The object of this little work is to supply the student with books for revision purposes and to carry about, and provided its use is limited to such purposes we consider that the publication is of undoubted service. There is given a brief résumé of the chief points regarding etiology, diagnosis, pathology, treatment, etc., of the most important maladies. The book has been revised and some new matter has been added. We are rather surprised to find that the author has placed chrome under the heading of nervous diseases, as this hardly coincides with the more modern conception of the etiology of this affection. We might also suggest that a short section on Baciliria should be included in the next edition. Judiciously employed, this small volume should prove useful, not only to the late of his examinations, but also to the busy practitioner or to the memory of many useful items of knowledge too easily forgotten in the rush of everyday work.

HERBAL SIMPLES. (b)

Is the "calling of simples" be a lost art in the twentieth century? We doubt it! We believe that the claims of herbal physic to therapeutic recognition have hitherto been based more or less upon empiricism. But there are signs that the remedial properties of many of the discarded herbs, seeds, and roots of the gardens and countryside are ben to be more appreciated as medicines. Scientific analysis has pointed out the virtues of many an obscure plant, so that at the present time the orthodox practitioner need not consider the use of approved herbal remedies beneath his notice when his customary medicines fail or are beyond speedy speed. For those desiring a detailed exposition of the healing remedies of every conceivable medicinal plant the work of Dr. Fernie may be cordially recommended. The veteran author, with a charm of language all his own, has, in the third edition of this unique handbook, incorporated several portions of his "Meals Medicinal," and he has given us a delicious compendium of folk-lore, medical history, botany and pharmacology. Its pages are replete with classic extracts and fragrant with the odor of rare and precious herbs for use in the healing of mankind. Here will be found all that is worth knowing about lavender and lettuce, mushrooms and mint, seed and spices. It deals with disease in alphabetical order, and there is an index of diseases indicating the dose for each. It is a book that may be read and re-read both for profit and pleasure, and the demand for it is sure to be great.

HEALTHY OLD AGE. (a)

The desire to live long and to see many days is innate in the majority of people, but so often the road to old age is anything but smooth, physically speaking. Many of the ills that beset the individual or near the end of his days are due to neglect of care and attention to be paid to hygiene and especially to diet. The little series of essays before us deals specifically with the prevention and treatment of the diseases that belong more or less to advancing years. The author believes that the true old age of a healthy folk should be nearer fourscore than seventy years, and that the extra years should not be those of labour and sorrow. The chief cause of the mortality in persons over sixty years in certain Australian and British, in connection with Bright's diseases or to the non-tubercular chronic chest diseases that are so frequently associated with them. Arteriosclerosis, consequently, receives special attention, and the advice given for the reduction of the tension of the blood pressure by diet, is sound and helpful. The author's son, Surgeon Gilbert Boody Scott, R.N., contributes a chapter upon the preparation of vaccines. Altogether this little book deserves a careful perusal by every medical practitioner.

A HANDBOOK OF HYGIENE. (b)

The present edition of this well-known manual, which has long been a favourite with students and practitioners, is further enriched by a thorough revision. The all-important question of the contamination of milk, more especially in relation to tuberculosis, is fully discussed, and recent official reports upon the subject are freely drawn upon. The section upon food-poisoning embraces those conditions due to the ingestion of some chemical poison (ptomaine) or to bacterial infection with organisms of the true Gaertner group. An account is also given of "onchocerciasis," a parasitic affection found in certain South American and American meat. In dealing with bread, the authors believe that the agitation in favour of a standard loaf will not have proved useless if it results in the creation of a public opinion adverse to any undue manipulation of grain during the milling process. Once permit the removal of certain portions of the grain, and the way is left open for chicanery of all sorts." A good account is given of pellagra, which is grouped under the heading of "Intoxications," and the theories regarding the etiology of beri-beri are adequately discussed. The question of venereal diseases is much more fully dealt with than is usual in a textbook of hygiene, and the authors, while asserting that "compulsory examination and registration of prostitutes is, therefore, merely tinkering with the fringe of the problem," believe that "the general feeling of the medical profession, in this country at least, would certainly not be in favour of what the majority would look on as a breach of professional confidence." The section on communicable diseases and their prevention is packed with information; indeed, it would be difficult to pick out any part of this excellent textbook which is not replete with the latest information upon the subject. In the "Addenda" of eight pages are contained some valuable notes from various official reports bearing upon the different sections of the book. We have pleasure in recommending this work as a trustworthy guide to the science and art of preventive medicine.

(a) "Aids to Medicine." By Bernard Hudson, M.D.Camb., M.R.C.P.Lond., Visiting Physician to the Queen Alexandra Sanatorium at Davos, late Assistant Physician to the City Road (Beth Israel) Hospital, etc. Second edition. London: Balliere, Tindall & Cox. 1914. Price 6s. 6d. net.

BOOKS FOR MOTHERS.

The seventeenth authorised edition of Dr. Chavasse's well-known handbook (a) upon the management and rearing of children has been re-arranged and re-written by Dr. T. D. Lister. The matter has now been placed in chapter form, thus doing away with the old method of dealing with the subject in a question and answer. The book, which has been a favourite among works of this class, cannot fail to enjoy continued popularity. The general directions with regard to giving drugs to children and to obtaining medical advice are improved with the use of a useful portable dictionary of useful appliances, medicines and sundries is placed in an appendix.

Another work of a similar, though less pretentious, character is Mrs. Usher's "Book for Mothers" (b), to which Dr. F. D. Rutter has contributed an introductory note. The following extract will illustrate the general character of the book:—"When the child gets a blow on the head, 'Pomade Divine' is the very best thing to put on." If a child has swallowed a pin or a piece of paper or anything sharp, send for a doctor, and a small piece of adhesive plaster (sic) can now use Röntgen-rays. Nevertheless, there are many useful hints, imparted in a homely style, which serve to render this little work a useful guide to mothers of the less educated classes.

MATERIA MEDICA, PHARMACOLOGY, ETC. (c)

It has been said that of late years the art of prescribing is in danger of becoming lost. That it seems to be so is due to the fact that the action of pharmaceutical remedies is largely taught apart from the bedside and also because a large number of drugs appear never to be used at all. Drugs, like everything else, have their day, no doubt, but the old adage that "the old fashioned medicines are the best" is still held in favour of the newer rivals. In the book before us the author has endeavoured throughout to emphasise the clinical aspect of each remedy described. The first portion deals with the various chemical and mechanical properties, and the second with methods of administration; the third section deals with prescription writing, and it contains many valuable hints for prescribers in general.

However, these are comparatively small points at which to cavil, for Dr. Basted's text-book contains far more practical information that is likely to be of real benefit to the student than the majority of similar works. An unique feature is the inclusion of several photographs of various drug eruptions, cartographic tracings, and X-ray pictures of the intestines. The third section deals with prescription writing, and it contains many valuable hints for prescribers in general. The index, though comprehensive, is far from complete, and it might be amplified. Dr. Basted is to be congratulated on recommending this manual as being a full and accurate guide to the use of remedies in the treatment of the sick.

CHEMISTRY AND ITS BORDERLAND. (a)

This is a good example of a book dealing with scientific facts, popularly written, designed to attract the attention of that reading public glad enough to gather up some pearls of science whose value they can recognise. Its purpose is to give the general reader an introduction to chemistry, and, to chemistry, and the author's aim is to show the relationship which this science bears to the other fields of scientific knowledge. In order to render his pages more comprehensible to non-technical readers, the author has dispensed with chemical jargon, but scientific advancement has taught us that the sciences with which chemistry has become closely allied are astronomy, physics, geology, physiology and pathology. The development of this theme is simple enough, and as the introduction to the subject of chemistry, it is scientific, but so well has the author succeeded in stringing his facts together that even by the scientist, the admission must be made that in the ground covered by the pages of this work, science is presented in a most attractive and lucid light. In the chapter on the relations between chemistry and industry, many facts are disclosed which cannot fail to instruct and interest the ordinary reader, and the same is true in respect to the chapter on immunisation. We have here a kindred voice of our city thorough, a subject to which references frequently occur in the newspaper press, and here we find a concise account of its discovery, its properties and uses, expressed in plain and untechnical language, which will satisfy little the reader of science but will be of use to many of the non-scientific reader.

There is a useful chapter on the Organisation of Chemical Research, describing the various channels open to the student in chemistry, by which his studies can be encouraged and helped as, for example, through a grant from the Research Grants and Research Scholarships. Herein, too, the student may learn the prospects in store for him, by adopting chemical research as a profession. It only remains to be added that the author has produced an interesting and attractive work, thoroughly deserving of a wide popularity.

YOUTH. (b)

This series of National Health Manuals is one of the characteristic features of the popular science harvest of the present generation, with its active and avowed object of bringing up the supply of the mental빈, and perhaps in symbolic writing, to the standard plane of the wave-front of the science and intelligence of his expert contemporaries. The present excellent booklet well represents the best features of this significant literature, which has so much influence on the attainments and outlook and consequent achievements of the rising generation. How widely the popular net is cast, and how reliable the quality of its scientific and moral, and generally educational and social, meshwork is, may be roughly guessed at by reference to the list of headings of the various (twelve) chapters; for the production and standardisation of each of which a distinguished name is found to be responsible. The introductory chapter deals with the general subject covered by the title of the volume, followed by consecutive series respectively devoted to: Growth and Development in Youth, Psychology, Hygiene of the Adolescent Girl, Mental Defects and Disorders, Education, Habits, Ethics, and Citizenship—all of the fruitful, as well as veracious, and often highly troublesome period of youth. How important the younger persons of our twentieth century must feel they are themselves, or that modern parents are being hourly provident for the support and propagation of this opinion! Full investigation of even any one of the series of endlessly labyrinthine questions discussed in this booklet, would be impossible within the limits of an ordinary review.

(c) "Youth." Edited by W. R. K. Kitching. M.D. London: Charles A. Kelly (National Health Manuals).
so we conclude our perfunctory notice by strongly recommending this comprehensive and intensely suggestive subject, and the collective theses thereon, here presented, to the close attention of every one of our readers.

NEW INVENTIONS.

WATTERS' STANDARD CHLOROFORM CATGUT.

MESSRS. ARNOLD AND SONS, surgical instrument manufacturers, have been appointed sole agents for the sale of Watters' standard chloroform catgut.

The principal points and advantages claimed for it are that it is cheap and convenient, and is the only catgut preserved in chloroform, which does not, like alcohol, cause the gut to become hard and brittle. It is easy to work with. The chloroform evaporates instantly, leaving a smooth, dry and pliable material. Another point is its absolute and unquestionable sterility, which eliminates entirely the danger of infection. It is also much stronger than any other, which permits the use of smaller sizes, imposing less burden upon the wound in the process of absorption. Its extensibility permits of its being closed and fastened close and fast with the minimum of strain.

It is antiseptic as well as aseptic, which prevents contamination in handling, and guards against the danger of the gut acting as a culture medium for the propagation of infection already in the wound.

INVESTIGATIONS by Major S. P. James, of the Indian Medical Services, show that of the fifty species of mosquito in Colombo only fifteen are harmful. Of the species observed some were previously unknown to science. Henceforward officers of the I.M.S. are to take a two-months’ course of tropical medicine immediately on arriving in India.—Indianman.

MEDICAL NEWS & PASS LISTS.

The Royal Medical Benevolent Fund Society of Ireland.

At a meeting of the Central Committee held at the Royal College of Surgeons of Ireland, it was stated that a donation of 20 guineas had been received from the President of the Royal College of Surgeons of Ireland. It was unanimously resolved: “That the thanks of the Central Committee be given to Mr. Conway Dwyer, President R.C.S., for his valuable donation of twenty guineas to the funds of the Society, and that he be hereby elected a life member of the Society.” Urgent applications, which were received too late for the annual distribution, were considered, and grants amounting to £24 were made, and bills amounting to £21 were paid for payment.

The Milk and Dairies Bill.

At a meeting of the Parliamentary Committee on Food and Health held at the House of Commons, and presided over by Mr. Charles Bathurst, M.P., on Friday last, the following resolution was moved by the Chairman, seconded by Sir W. Phipson Beale, M.P., and carried unanimously. The Parliamentary Committee on Health cordially supports the Milk and Dairies Bill and Milk and Dairies (Scotland) Bill, as measures designed to secure to the community an unrestricted supply of pure milk, with the minimum amount of danger to the consumer. While recognising them to be capable of improvement in some details, it earnestly depreciates the insincerity on drastic amendments, as calculated gravely to imperil the passage of Bills long overdue and of vital importance to the health of the people and of children. The Committee trusts, however, that a clause, sanctioning the sale of ‘certified milk,’ which is in the United States has played so conspicuous a part in raising the milk standard and in forming public opinion in favor of pure milk, is in the general consent and in the interests alike of producers and consumers, be included in both measures,”

Naval Medical Reserve.

It is announced that, with the view of affording officers of the Naval Medical Reserve opportunities of keeping in touch with the Naval Service in time of peace, the King has been pleased, by an Order in Council published in the London Gazette on June 19th, to approve of the establishment of a two-months’ course of instruction during peace under the following conditions:—[1] To receive full pay at the rate of £175 a day while re-employed or undergoing courses of instruction; (2) to be under the same conditions as regards pension, etc., in case of death or injury as would be applicable in the event of their being called upon to serve in time of war or emergency.

Medical Meeting at Worthing.

The inaugural meeting of the newly-constituted Sussex Branch of the British Medical Association was held at Worthing the other day. Dr. Ayton Goodchild, of Worthing, was elected the first chairman of the Branch. After the transaction of formal business, the members, numbering about 40, were entertained by Dr. and Mrs. Gustling to lunch, and subsequently to a garden party at their residence in Richmond Road.

Royal Hospital for Incurables—Annual General Meeting.

The annual general meeting of the Royal Hospital for Incurables, Donnybrook, was held in the Board-room of the Hospital last Wednesday, William Fry, J.P., Chairman of the Managing Committee, presided.

The annual report stated:—The Hospital at present contains 213 beds, and during the past year there were no less than 283 applications for admission; of the successful candidates ten were affected with consumption, nine with cancer, ten with paralysis and nervous diseases, four with cardiac and vascular diseases, four with rheumatism and arthritis, the remaining 102 were affected with various forms of incurable disease. In addition to filling the beds at each election, and with a view to further extending the benefits conferred by the Hospital on suffering humanity, the Governors elect two patients as pensioners, and who receive a weekly cash allowance from the funds, pending their admission to the Hospital. It is interesting to record that, of the 213 patients remaining in the Hospital on March 31st, 1914, no less than 35, or over 16 per cent., were affected with paralysis or incurable diseases. The time spent in the Hospital by these sufferers amounted in the aggregate to 47 years 6 months, giving an average of 6 years and 7 months for each patient. These particulars are furnished to prove that health and suffering are not restricted to the poorer classes, and that the patient who is incapacitated for work, and is provided with food, clothing, and medical attention, is taken care of as long as he is able to retain his faculties, and is willing to try to support himself. The total cost of maintaining a bed, all charges included, amounted to £17 4s. 6d., which is practically the same as last year. The average attendance of Governors at the eight evenings held during the year was 15, as compared with 148 the previous year. It is interesting to state that at an election for female patients, held on December 10th, 1913, no less than 228 Governors were present in person to vote, a
record attendance at an election of patients. The ordinary expenditure side of the account shows a decrease, £2,817 3s. od., as compared with £5,888 10s. 4d., which, with the increase in the age of the patients, which may be regarded as satisfactory, having regard to the increased cost of living and provisions.

University of Durham Faculty of Medicine.

At the Convocation held on Tuesday, June 23rd, 1914, the following degrees were conferred:

Bachelor of Medicine—James Toseph, John H. J. Toseph, John J. Toseph, Joseph John (Chemistry H. Butterly, Medicine."

The following received the Licence in Dental Surgery (L.D.S.)—John T. Smith, Sidney Wilkinson.

At the second examination for the degree of Bachelor of Medicine the following candidates satisfied the examiners:

Matury and Physiology.—William Andrew Hewitson, honours, first class; Harold M. Leete, honours, second class.

The following candidates passed the third examination for the degree of Bachelor of Medicine—

University College, Dublin.

The examiners have made the following recommendations to the Senate—

First University Examination in Medicine—

Honours: Thomas F. M'Kinney, M.A., first-class honours Parts I. and II.; Nicholas Maher, ditto; Michael H. Murphy, ditto; Michael H. Murphy, second-class honours Parts I. and II.; James H. O'Connell, ditto; Hubert Mcken, second-class honours Part I.; John F. Cunnigham, ditto; Thomas J. Murphy, ditto; James J. Gullick, ditto; James J. Gullick, second-class honours Parts I. and II.; Charles J. Smurthwaite, ditto; James J. Gullick, second-class honours Part I.; John W. Healy, second-class honours Parts I. and II.; Joseph B. M'Arevey, second-class honours Parts I. and II.; William J. O'Connell, ditto.

University College, Galway—Provisional Results.

The following are the recommendations of the examiners for the summer term, 1914:

Medicine.—Second-class honours: Michael Hanly.

University College, Dublin—School of Physic.

The following passed the preliminary scientific medical examination, Trinity term—

Physics.—Lionel Wigoder.

Botany and Zoology.—Richard P. Hemphill, Lindley Albertyn (Jr.), Archie Acheson, Richard G. M'Elwee, equal; James F. O'Sullivan, on high marks; Edward W. Wilson, Gertrude Rice, William B. Briggs; Sidney A. Clark and Wilfrid L. Lloyd, equal; William L. Young; George H. Davis and John W. Scharff, equal; Samuel W. Russell; Ernest B. Edge and Albert H. Thompson, equal; Charles W. Parr, Henry A. Larelle; Robert M. D. Dove, Ernest E. Rollins and William F. M'Connell, equal; John E. McCormick, John H. Coolican, Thomas Madill, and John F. Stewart, equal; Ernest F. W. Smith, Edward R. Birdseye, Eric S. Eack, equal; Ernest E. Rollins and Ivan W. Beatty, equal; Athisus Blagoff, Thomas R. Warren, Richard N. Nunn, Herbert J. Wright; George C. Robb and William W. Shortt, equal; John Ryan, equal; Patrick Casey; Frederick W. Godfrey and William A. Shannon, equal; Samuel J. Laverty, George R. G. Smyth.

Trinity College, Dublin—School of Physic.

The following passed the preliminary scientific medical examination, Trinity term:

Physics.—Lionel Wigoder.

Botany and Zoology.—Richard P. Hemphill, Lindley Albertyn (Jr.), Archie Acheson, Richard G. M'Elwee, equal; James F. O'Sullivan, on high marks; Edward W. Wilson, Gertrude Rice, William B. Briggs; Sidney A. Clark and Wilfrid L. Lloyd, equal; William L. Young; George H. Davis and John W. Scharff, equal; Samuel W. Russell; Ernest B. Edge and Albert H. Thompson, equal; Charles W. Parr, Henry A. Larelle; Robert M. D. Dove, Ernest E. Rollins and William F. M'Connell, equal; John E. McCormick, John H. Coolican, Thomas Madill, and John F. Stewart, equal; Ernest F. W. Smith, Edward R. Birdseye, Eric S. Eack, equal; Ernest E. Rollins and Ivan W. Beatty, equal; Athisus Blagoff, Thomas R. Warren, Richard N. Nunn, Herbert J. Wright; George C. Robb and William W. Shortt, equal; John Ryan, equal; Patrick Casey; Frederick W. Godfrey and William A. Shannon, equal; Samuel J. Laverty, George R. G. Smyth.

John D. Watson.

Botany—James M. Hill.

Intermediate medical examination—

Part I.—Edward D'A. McCrea, William R. Fearon and Bryan A. O'Sweeney, passed on high marks; Alexander R. Barlas and Arthur L. Gregg, equal; Randolph B. Murray, William P. Elford, William H. Flynn and Stanley C. Mitchell, equal; James J. Beasley and Willem P. Lubbe, equal; Frederick J. Smith; Charles P. Chambers and George W. B. Shaw, equal; Philip S. 5nell, William...
NOTICES TO CORRESPONDENTS, 8c.

Dr. Henry Hutchinson Stewart Medical Scholarship (Anatomy and Institutes of Medicine).—Alan F. Grinstead.

The Daniel John Cunningham Memorial Medal and Prize.—Edward D'A. McCrea.

The Fitzpatrick Scholarship.—John D. Oliver.

Licentiate in Medicine, Chirurgia et Arte Obstetricia.—Edwardus Evans, Jacobus Henrikus Fletcher.

Baccalaureus in Scientia Dentaria.—Mary de Sales Magennis.

Baccalaurei in Medicina, in Chirurgia, et in Arte Obstetricia.—Theodoricus Wright, Albertus I. Pope, Banke, Augustinus Linn, Fredericus I. Alix, Alexanus Wood.

Edinburgh University.

The following candidates have passed the final examination for degrees in medicine and Surgery (M.B., Ch.B.)—Edvardus I. Alexander, Christophorus D. H. Dockrill, Samuel E. Elliott, William O. Tobias, Amy F. Nash, John S. Dockrill, James H. Fletcher.

Preliminary scientific dental examination:—Chemistry and Physics.—Henry E. Flavelle, John H. S. Stuart.

Chemistry.—Lionel Wighoder.

Dental Anatomy.—Henry E. Flavelle.

Intermediate Dental Examination:—Maurice L. Connham, Charles H. Herbert.

Final Dental Examination:—Mathias S. Magennis.

Scholarships and Prize Examinations:—Surgical Travelling Prize and Bennett Medal.—Arthur Chance, M.B., Bennett Prize for Surgery.—Georgia Revington.

Medical Scholarships:—Anatomy and Institutes of Medicine.—Robert C. B. Ramsay.

Chemistry, Physics, Botany, and Zoology.—Harry E. Parker.

Dr. Henry Hutchinson Stewart Medical Scholarship (Anatomy and Institutes of Medicine).—Alan F. Grinstead.

The John Mallet Purser Medal.—William R. Fearn.

The Daniel John Cunningham Memorial Medal and Prize.—Edward D'A. McCrea.

The Fitzpatrick Scholarship.—John D. Oliver.

The following degrees and degrees were conferred at the commencements on June 30th:—

NOTICES TO CORRESPONDENTS, The Medical Press. 53.
Conferences are kindly requested to send their communications to the Editorial office, to be handed to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in redrafting the same. Wherever sending sub-
scriptions the same rule applies as to office; these should be addressed to the Publisher.

ADVERTISEMENTS

For One Insertion—Whole Page, £5; Half Page, £2 10d.; Quarter Page, £1 3s.; One-eighth, 6s. 6d.
The following rates are made for Half-Page—Whole Page, 13 insertions at £2 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for larger spaces.
Small advertisements of Practices, Assistantships, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion, and 2s. 6d. per word beyond.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated by a certificate of authenticity from the author or writer, not necessarily for publication, but as evidence of identity.

Prints—Reprints of articles appearing in the Journal may be had at the rates prescribed, provided after giving notice to the publisher or printer before the type has been distributed.

This should be done when returning proofs.

M.B., B.Ch. (Kenty).—The red sulphide of mercury is preferable to the ammoniated salts in dealing with skin infections of the scalp. It may be combined with sublimate sulphur with advantage.

Dr. A. R. (London, S.E.).—The case appears to be a peculiarly one suitable for treatment by psychotherapy. There is a physical basis for the mental symptoms. N. R. (Brighton).—There are very few lepers in London at the present time, but the Hospital would doubtless be able to study the general characteristics of the disease in the wards of the Seamen's Hospital, Greenwich.

Vacancies.

West Harptpool:—Cameron House. — House Surgeon. Salary £150 per annum, with board and rooms. Applications to J. G. Taylor, Secretary.

Camberwell Tuberculosis Dispensary, 19 Brunswick Square, S.E.—Assistant Medical Officer. Salary £250 per annum. Application to the Secretary.

University of London, University College.—Lecturer and Demonstrator in Anatomy. Salary £150 per annum. Applications to Walter W. Seton, M.A., Secretary, University College, Gower Street, W.C.

Bradfield General Hospital.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to红色 Conservative, 24 Gower Street, W.C.

Birmingham General Dispensary.—Resident Medical Officer. Salary £250 per annum, with furnished apartments, fire, light, and attendance. Applications to Ernest W. Forrest, Secretary, 32 Union Street.

Hubert Street, Darlington:—Stretford Road, Manchester. — House Surgeon. Salary £150 per annum, with apartments, attendance, coal, and gas. Applications to Honorary Medical Officer, 49 Stretford Road, Manchester.

County Borough of Preston.—School Medical Officer, Salary £250 per annum. Application to the Honorary Medical Officer, Town Clerk.

County Borough of Salford:—Perse Hospital.—Junior Resident Medical Officer, Salary £250 per annum, with apartments, etc. Applications to L. C. Evans, Town Clerk.

Weston-super-Mare Hospital.—House Surgeon. Salary £200 per annum, with residence, board, and hospital in the district. Application to the Honorary Medical Officer, 80 Birkenhead Road, Weston-super-Mare, S.E.—Second Assistant Medical Officer, Salary £253 per annum. Applications to John L. Workshop Acts, Southwell Royal Hospital, New Bridge Street, E.C. (See Advt.)

Appointments.

DEANS.—H. V., M.R.C.S., L.R.C.P.Crow.—House Physician at University College Hospital.

DICKINSON, W. E., M.R.C.S., L.R.C.P.—Registrar in the Department of the Royal Hospital for Diseases of the Chest, City Road, E.C.

GERRARD, J. C., F.R.C.S.—Senior Demonstrator in Surgery under the Workmen's Compensation Act, 1906, for County Court Circuit E.

JOHNS, HOWARD, M.B., B.Ch., M.R.C.S., L.R.C.P., Honorary Physician to St. Mark's Hospital for Diseases of the Skin.

NYE, CHARLES, M.B., B.Ch., M.R.C.S., L.R.C.P.—Medical Officer of Health of Bromley.

RICE, F., M.B., B.Ch., M.R.C.S., L.R.C.P.—Obstetric Assistant at University College Hospital.

STOKES, F. J., M.R.C.S., L.R.C.P.—Assistant Dental Surgeon at the Royal Dental Hospital.

TURNER, E. B., M.B., B.Ch., M.R.C.S.—Surgeon, Westminster Hospital College Hospital.

FINN.—On June 24th, at 15 Elberry Street, Easton Square, S.W., the wife of Allan Finn, M.D., F.R.C.S.—A son.

GREEN.—On June 24th, at 24 Hampshire Road, Earlsfield, the wife of Charles David Green, M.R.C.S., L.R.C.P., Eng., of a daughter.

HOLLAND.—On June 24th, at 13 Berwick Road, Palmer's Green, London, N., a baby girl, 3lbs. 4oz., to Mr. and Mrs. W. Hollis.—Molly—8s.

LYON.—On June 24th, at 53, Acreca Road, N.W., the wife of T. B. Layton, M.S., of a daughter.

MARSHALL.—On July 1st, at 46, West End, Ealing, the wife of Mr. Henry Marshall, of a daughter.

PITKE.—On June 24th, at Richmond House, Langford, Somerset, the wife of Ernest P. Mace, M.R.C.S., L.R.C.P., Eng., of a daughter.

Marriages.

ABBEY.—On July 1st, at the Roman Catholic Church, Richmondworth, William J. Ashley, M.D., B.Ch., B.A., of Arkley, and Miss Kathleen Ann Morley, youngest daughter of Hilda Lamore, second daughter of Mrs. Latimer Sayer, of Lake View, Northwood.

BACON.—On July 2nd, at Highfield Church, Earl's Heath, Lancet at Bromley, M.R.C.S., youngest son of Sir John and Lady Bromley, of Saffron, Sussex, to Doris Bullock, youngest daughter of Mr. and Mrs. Arthur Lee, High Close, Earl's Heath, Yorks.

CANE.—On July 2nd, at Trinity Wesleyan Church, Wealshaw, with the consent of the Minister, Catherine Jane Martin’s-in-the-Fields, Tringal Square, Lionel Charles William Jane, M.R.C.S., L.H.Sc., of London, to Elma, eldest daughter of Mr. and Mrs. Guyot, of Welbeck, Kent.

CRUMP.—On July 2nd, at Trinity Wesleyan Church, Hulme, the late F. S. Crump, to Miss Hedger Elizabeth, only daughter of Mr. and Mrs. Whitfield, of Salford, Manchester.

HOBBS.—On July 2nd, at St. George's Hanover Square, Basil Hughes, F.R.C.S., son of the late T. F. Hobbs, M.R.C.S., of Liverpool, to Jane Ann Sellars, of Swindon; London, of the late George Campbell, Surgeon, of Christ Church, London, of the late George Campbell, Surgeon, of Christ Church, London.

FAWCE.—On July 2nd, at Christ Church, Aughton, Robert Anthony Fawce, M.R.C.S., youngest son of the late Ernest Fawce, of Aughton, Cheshire, and Mr. Howes, of Ego, Sussex, to Doris Anna, daughter of Mr. and Mrs. Howes, of Ego, Sussex.

HUNTS.—On July 2nd, at St. Peter's Church, Birmingham, John Henry Hunt, M.R.C.S., L.L.B., of Coventry, to Miss Bertha Hope, of the late Mr. and Mrs. Smith, of the late Mr. and Mrs. Smith, of Coventry.

O'CONNOR.—On July 2nd, at St. Etheldreda's, the eldest daughter of the late Dr. W. M. O'Connor, of Bromley, Cheshire, and Miss Hall, of Ewell, Epsom.

ODER.—On July 2nd, at All Saints, Walthamstow, to Miss Dorothy Ursula, daughter of Mr. and Mrs. J. W. Oder, of the late Rev. Dr. Osger, of Oxford, to Mabel, youngest daughter of G. Randell Higgins, The Court, Boreham-
thorpe, Essex.

SEQUEIRA.—On July 2nd, at St. Matthias, Richmond, to Miss Grace Sequiera, R.N., Miss Grace Sequiera, R.N., of Engineer Rear-Admiral W. G. Littlejohns, of Stoke, Devonport.

Deaths.

ANDERSON.—On June 29th, at 3, Arundel Terrace, William Christopher Anderson, M.A.St.And., M.B., C.M.Ed., late of Chelsea, aged 49 years.

BETTS.—On June 29th, at Darjeeling, John Hay Burgess, M.R.C.S., L.R.C.P., late of 15, Ballymoney Road, to His Excellency the Governor of Bengal, aged 34 years.

FOSTER.—On June 29th, at Lilacross, as the result of an accident, Henry Richard Foster, M.R.C.S., L.A.S., and Mr. Horsels.—On June 29th, George Herschell, of 36 Harley Street, M.D., late of 37, Mayfair, as the result of a gas accident. John Augustus Hogg, M.R.C.S., L.R.C.P., aged 45, of 37, Mayfair, and 4th Avenue, Narragansett, R.I., Miss Roberts, L.D.S., to Robert Lowth, M.D., F.R.C.S., Eng., in his 73rd year.

MAGS.—On June 30th, at Bury Hatch End, George Maggs, M.D., aged 89 years.

VACHEL.—On July 2nd, at a nursing home at Clifton, Charles Tanfield Vachell, M.D., London, of Cardiff, aged 65 years.

HULME DISPENSARY.

DALE STREET, STRETFORD ROAD, MANCHESTER.

WANTED—a House Surgeon duly registered and fully qualified, Salary £180 per annum in cash; applications, with testimonials, at once, to Honorary Medical Secretary.
NOTES AND COMMENTS.

Officious Sick Visitors.

The advent of the inspecting school and insurance sick visitor has been one of happy omen. At the same time the ultimate and general success of this modern departure must to a great extent depend on the tactfulness of the officials who do the visiting. In cases that have come under our personal knowledge school visitors have taken the responsibility of pronouncing a ringworm cured, and have advised a child's return to school; or they have under-taken to decide whether in a given case ringworm is or is not present. As a matter of fact, it requires long medical training and the assistance of a microscope, and possibly of bacteriological investigation as well to enable one to pronounce with confidence upon the highly technical points in question. In the majority of cases it is absolutely impossible for the sick visitor to give any opinion on the point that is of the slightest value. This fact should be grasped by all local authorities that wish to deal adequately with the scourge of ringworm within their area. With care and experience a lay visitor may, of course, learn a good deal about ringworm, but it may be repeated with emphasis that it requires medical skill of a high order, backed by scientific methods of investigation, to ascertain not only the diagnosis, but also the cure of many cases of ringworm.

Under the National Insurance Act it becomes possible for a rash or over-zealous sick visitor to do a great deal of mischief. The functions of such an official are to see that patients have medical attendance and that they are carrying out treatment properly. It is clear that in this way they discharge an important duty as regards the efficiency of medical administration and prevention of malingering and imposition. An instance of undue interference on the part of a sick visitor was reported last week by Dr. Harry Roberts. The patient was suffering from "housemaid's knee," for which complete rest was ordered. The visitor, according to the patient's statement, ordered her to return to work. The knee naturally got worse and a surgical operation became necessary. Incredible as it may seem, the visitor is said to have ordered the bandages to be removed in order that the wound might be inspected. A step of that kind might induce sepsis, with the possibility of permanent damage or even of fatal results. In view of the importance of the sick visitor to the adequate administration of the Insurance Act it would be well for the Insurance Commissioners to draw up a code of rules for their guidance. Sufficient time has now elapsed since the introduction of the Act for the adoption of common-sense principles in its practical working.

"Certified" Milk.

The importance of pure milk as a factor in public health is being more and more recognised by the legislature. The latest departure is the adoption of Mr. Astor's motion to authorise "certified milk" by the Standing Committee of the House of Commons for the better regulation of the supply of milk and the conduct of dairies. The mover aimed at the authorisation of the term "certified milk" for milk produced under prescribed conditions, and prohibiting the use of such description to milk not protected in that way. This proposal was accepted by Mr. Herbert Samuel, the President of the Local Government Board, on behalf of the Government. He pointed out that while provision might be made by legislation for the sale of dirty milk, difficulty was often experienced in enforcing penalties. Much might be done if the stimulus of a higher rate of profit could be given to those traders who offered milk produced and sold under a system of official regulation and inspection. Unless Parliament dealt with the matter a system of certification by private organisations would probably spring up. The adoption of this public guarantee, so to speak, of the purity of milk thus specified is clearly a departure of great practical importance.

Forcible Feeding.

A petition on the subject of the forcible feeding of prisoners, with special reference to suicide, was presented last week to the Home Secretary by a number of registered medical practitioners. Some considerable divergence of opinion exists, even among medical men, as to the propriety of this procedure. Impartialy considered, it may be said at once that forcible feeding is never resorted to unless it be in the interest of the health of the prisoner herself. Mr. McKenna has forwarded a reply to the petitioners emphasising this view of the treatment. The document proceeds in the following terms:—"The prisoners who are now being forcibly fed include the two women who burned a hotel at Felpham; the woman who burned the pavilion at Kew Gardens; the woman who burned Lady White's house at Englefield Green, and who attacked the Rokeby Venus in the National Gallery; two women who damaged pictures in the Royal Academy; one who attempted to destroy an antiquity in the British Museum; and two who were found in possession of explosives, one of them on the occasion of the King's visit to Nottingham. The Secretary of State assumes that the petitioners do not desire that these women should be allowed to starve themselves to death in prison, and that what they ask for is their release. This would mean that the women would be set at liberty, with the practical certainty that within a week or two they will burn more houses, destroy more
works of art, and commit further outrages. In these circumstances the Secretary of State feels that it would be inconsistent with his duty to the public to grant the immediate release of its offenders, but if the petitioners, on the basis of their medical experience and skill, can attest any practical method other than forcible feeding by which the life and health of prisoners who persistently starve themselves and who ought not to be released may be preserved, Mr. McKenna will be only too happy to consider it. Here is a nice little clinical problem awaiting a satisfactory solution.

Sir Jonathan Hutchinson's columns to the unique educational museum established at Haslemere through the wonderful energy and enterprise of the late Sir Jonathan Hutchinson. A powerful appeal has recently appeared in the Times from the pen of Sir Archibald Geilke for a sum of at least £8,000 to maintain the institution in the same state of efficiency as it was left by its revered founder. It is estimated that the museum is visited by some 10,000 persons annually, many of whom are pupils brought from schools at considerable distances. Unfortunately, the fund, although large, is wholly insufficient to enable this wonderful institution to fulfil its function of instructing the public in biological, geological, and natural history through the aid of carefully selected specimens and illuminating diagrams. The residents of the district have risen nobly to the occasion, and have agreed, it is said, to maintain the museum until the end of the present year, but much more than this is needed. As a permanent memorial to the genius and skill of Sir Jonathan Hutchinson it would be an incalculable loss to the public, as well as to science, were the establishment to languish for want of timely support. There must be many medical men as well as laymen who would willingly contribute towards its preservation and permanent endowment out of personal admiration and gratitude to its founder. The Hon. Secretary and Treasurer of the fund, Miss Rose Jackson, Downcourt, Haslemere, will gladly receive subscriptions for this object.

Elsewhere in our columns will be found the report of an unfortunate occurrence at a London hospital. A girl had four teeth extracted, and upon recovering from the gas she appeared to be in a somewhat distressed condition. The operator, Mr. C. Peyton Baly, the well-known dental surgeon of Harley Street, according to the report, reached down a bottle which he supposed to contain smelling salts and applied it to the patient's nose. Unfortunately he had taken a bottle of corrosive acid, whereby considerable damage was inflicted upon the patient's face and neck. The explanation given was that the bottle of acid ought not to have been in the cupboard at all. A chain since made for damages on account of negligence was sustained by the learned judge. The assessment of damages has been postponed in order to see if the scar could be mitigated by the application of X-rays. The accident is one that might happen in any one of our hospitals, and Mr. Baly will have universal sympathy in his misfortune. As to the moral of the incident—it is clear that all hospitals should keep their poisons in distinctive bottles. Had the acid been in a properly shaped receptacle the gruesome accident above recorded would not have taken place.

LEADING ARTICLES.

UNQUALIFIED MEDICAL PRACTICE.

The scientific care of the public health has of late years advanced by leaps and bounds. The Public Health Acts have placed sanitary administration upon a sound basis, and have reduced the death-rates materially, to say nothing of the improvement that must sooner or later follow in the thaws and sinews, so to speak, of the nation. The medical inspection and treatment, combined with systematic feeding, of school children has been another step in the same direction. Not least of these measures is the National Insurance Act, which, in spite of various defects, cannot fail in the long run to exert a powerful influence in advancing the national health. In sharp contrast with these advances is the survival of the evils of unqualified medical practice. When King Henry VIII. instituted State medical qualifications in the sixteenth century, the change was explicitly inaugurated in order to enable the public to distinguish between properly educated and approved practitioners and those who had not gone through any systematic course of training and satisfied the ordeal of the orthodox examination. That which was necessary four hundred years ago, when the best medical knowledge was crude and empirical, is a hundred times more desirable nowadays, when the practice of medicine has acquired, and is still acquiring, a mastery over the wide and enormously complicated field of practical medicine that constitutes it one of the most fascinating and progressive of all the sciences. It is not a little curious that the modern encroachments on the liberty of the individual subject in the interests of the community should have halted and failed before the foul abuses of unqualified medical practice. This deplorable failure has probably arisen mainly from two causes: First, the extent of the vested interests involved; and, secondly, the fact that the medical profession has not in the General Medical Council a body strong and capable of protecting the conditions of medical practice, as regards both the public and the profession concerned, in a manner analogous to that exercised by the Incorporated Law Society. The outcome, at any rate, is that, whereas the British public is rigorously protected from the unlicensed lawyer, it lies at the mercy of any medically unqualified charlatan, no matter how bottomless the void of his folly, greed, recklessness, and cruelty. A striking instance of the definitiveness of the law in dealing with unqualified practice is the way in which so-called Christian Science healers are permitted to continue their dangerous calling practically without restraint. From time to time deaths occur amongst those who have been misguided enough to trust to their ministrations, but the "healer" escapes with mild judicial censure. It is nothing short of a scandal to our modern civilization that ignorant persons should be permitted to endanger life by claiming the power and usurping the position of a State-qualified practitioner of
medicine. Only last week, in a coroner's court, an inquest was held upon a lady who died in the house, at Isleworth, of Mr. Orlando Miller, described as a "teacher, lecturer and healer." He was without medical qualification, but had received deacons into his house "to see if he could cure her of paralysis," for which services he was paid five guineas a week. Medical evidence was to the effect that a medical man been called in earlier the life of deceased might have been saved. "She was a poor subject for taking drugs," said a doctor who had formerly attended deceased, a remark that derived its significance from the fact that Dr. W. H. Wilcox, of the Home Office, detected scopalamine in the viscera of deceased. The coroner observed that the administration of scopalamine was not a wise or proper treatment for a person in the condition shown to have been that of the deceased during her last illness. The jury asked that the coroner should severely censure Mr. Miller for having administered a dangerous drug that might have accelerated death. The coroner pointed out to Mr. Miller that he was deserving of the greatest blame for treating the woman in a very improper way. Fortunately for him the medical evidence was in his favour, or he might have found himself in difficulties. There the matter ends. Mr. Miller, if we remember aught, has received somewhat similar admonitions from various other coroners. Surely there is something wrong with the law which permits the recurrence of this scandal of unqualified medical practice. Mr. Lloyd George would do well to insert a corner stone, without which his public health edifice will remain rotten and unstable, by legislating against the pernicious practices of the charlatan. Fortunately he is not afraid of fighting vested interests, which apparently have proved too strong for the recent Select Committee of Inquiry upon proprietary medicines and unqualified practice. On the appointment of that committee we had private information of an authoritative nature to the effect that no result of any value would ever come of the inquiry which would be allowed to drop quietly out of existence.

One fatal defect of the committee, if our information is correct, was that the British Medical Association was permitted practically to guide its policy and nominate its witnesses. In view of its untoward experiences in the National Insurance Act, the Government might surely have grasped the elementary fact that the Association does not fully represent the thoughts, wishes, and aspirations of the medical profession. Any Cabinet Minister seeking guidance of the Council of that body is likely to be favoured with the personal views of a knot of wirepullers. The only sense in which the Association is representative is that it is the concrete sign and symbol of organisation. Some day it will doubtless emerge into the open light as an impartial and fearless defender of medical men in their various relations to society. What has the Association achieved during its many years of existence in the actual suppression of unqualified practice?

CURRENT TOPICS.

Insurance.

We have a modern way of reducing everything to a type. There is hardly a person or a thing that we do not classify and generalise about. We talk about "the school child" or "the working-man" as if each member who falls under either title must be in need of physical, mental or moral admomitions and correction, and a counterpart of all his fellows. It is our poor little way of tackling things that are too big for us. We cannot pay attention to each school child and solve its individual problems and difficulties, and so we turn our energies to the alleged troubles of "the school child," and forget that nobody is average. In a like way we are all too ready to lump in the greatest or smallest errors, and forget that we are dealing with individuals, with men of fate. We try to mitigate our lot when fortune is unkind by tempering our pleasures when she smiles. We are moderate, and we insure. It is all very wise and unromantic. At least, most of it is, but there are some kinds of insurance that are almost interesting. Sporting policies will insure one against anything, from twins to bad weather, or pneumonia, but no irrevocably. influenza, bronchitis, or non-suppurative tonsillitis. The taking out of an insurance policy has a certain therapeutic value. It acts like an amulet. The insured person enjoys health above the average, and annuitants are notoriously long-lived. The insurance companies have done a great deal to reduce the frequency of appendicitis. They have encouraged doctors to refuse their services for £100 to £1, and say that the malady has abated substantially. It is this sort of case that makes therapeutics seem easy.

Coloured Thinking.

Ever since the time of John Locke it has been known that certain persons are able to associate sounds, words, or places, with colours. Such people may be either normal or abnormal mentally. They are rather to be classed among those refined thinkers that are akin to geniuses. In the current number of Science Progress, Professor David Fraser Harris, M.D., D.Sc., of Dalhousie University, Halifax, N.S., describes this peculiar mental faculty which has been termed psychochromesthesia, coloured thinking, or chromatic conception. The linking together of colours with names of places, sounds, physical sensations, days of the week, etc., takes place in the mind of the thinker directly the mental concept is visualised, or as soon as it has entered the field of conscious thought. Thus, to some coloured thinkers Sunday may be yellow, Wednesday blue or brown, Friday black and so on. In fact we cannot compare the tone of a singer's voice to a certain colour. The expression "Moonlight Sonata" itself is a true colour-phonism, and this and similar associations frequently appear in the pages of modern novels. As Professor Harris points out, chromatic conception belongs to the physiology, not to the psychology of mind, and perhaps has its origin in the past. Features of psychochromesthesia are very definite. Thus the associations are generally fixed in the mind at a very early age, and when once the colour is thought of it is never dissociated from its own particular mental concept. Again, the coloured thinker is always most careful to define precisely the particular shade of colour he has thought of in connection with any object, though different

CURRENT TOPICS.

THE MEDICAL PRESS. 57
coloured thinkers will not associate the same colour to the same mental concept. No reason can be given for this strange propensity of mind, which is sometimes hereditary, and may be related to symbolism.

**Aerophagy.**

The swallowing of air, followed by eructations, is associated with many disorders of the alimentary canal. At one time it was believed that aerophagy was more or less pathognomonic of a neuritis, but this troublesome symptom undoubtedly occurs in several organic gastro-intestinal diseases. In an interesting paper upon the subject read last month before the American Gastro-Enterological Association at Atlantic City, Dr. Charles D. Aaron, of Insurance Act. This, of course, is a matter that concerns the doctor alone, but a notice was moved bringing the refusals to the notice of the Board. A typical argument—if it can be so called—was introduced: That "a person getting medical relief is as much entitled to get a certificate as to get a copy of the registration when death occurred." Because a dispensary officer is paid to administer medical relief, and to issue copies of certain registration certificates, he is therefore in the position of general guardian angel to the proud possessor of the red ticket, and must do everything else for the latter's convenience. Why not ask the doctor to feed and nurse the sick man, run errands for him, and help to wash his hands? The whole plan be for the public good, and if the doctor is not paid for looking after the sick, what is he paid for? At the meeting it was explained that neither the guardians nor the Local Government Board had anything to say to the Insurance Act, and this wonderful fact ultimately reached through the periphery of the un-dispised omniscience. And if many other public bodies, they had been talking for quite a long time about something they knew nothing about and which did not concern them in the least. Their only justification was that they were trying to get more work out of their doctors with absolutely no extra expense on the funds committed to their charge. They also overlooked the fact that someone else is being paid out of public funds for non-performance of the duty they wished to impose on their medical officers.

**The House in Relation to Tuberculosis.**

One of the greatest problems in the national campaign against tuberculosis is the prevention of the disease in the home. After years of increasing activity and wider recognition on the part of health authorities, resulting in State benefit for the consumptive, public attention is gradually becoming more and more concentrated upon the chief mode of infection—the insanitary dwelling. It was most appropriate, therefore, that the subject should have been among those selected for discussion at the sixth annual conference of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, held at Leeds last week. As a member of the Royal Commission which is at present investigating the whole question of the housing of the people in Scotland, Sir William Younger, Bart., in his opening address, pointed out the remarkable saving in human lives that has been effected in Liverpool as the result of the demolition of one insanitary area and the conclusion thereupon of bright and airy dwellings surrounded by plenty of space. The educative aspect of the question, in so far as it comes within the scope of the tuberculosis dispensary, was dealt with by Sir Robert Philip, M.D., who declared emphatically that it should constitute an offence to offer consumption at a charge for the patient to expose infected milk or meat for human consumption. While much can be done in enforcing the object lesson of the sanatorium in the home, true advance against tuberculosis will be accomplished only in so far as the necessity for an abundant supply of fresh air, especially for the developing child, is accepted as a necessity by all local authorities throughout the country.

**Deramitits in Rose-gatherers in the Riviera.**

The occurrence of an inflammatory form of dermatitis upon the hands of persons engaged in horticultural pursuits is well known. A number of flowers and plants are capable of giving rise to troublesome cutaneous eruptions when handled by susceptible individuals, and the rash is gradually increasing as the result of careful clinical observation and research. Only a short while ago an investigation into a rash affecting the rose-gatherers in the Scilly Isles was undertaken by Dr. David Walsh, who came to the conclusion that in a large number of instances the eruption depended upon some circulatory defect, usually of cardiac origin. In a recent number of the Lyon Médical, Dr. Revillet of Cannes, calls attention to certain affections of the hands among the workers in the rose industry in the Riviera. The lesions are in the main produced by traumatisms, the thorn-punctures being infected with septic microorganisms. Hence, whitlow and boils are frequently observed, while a common type is that of a vesicopustular dermatitis resembling at first sight a scabies, even in its distribution. Carbuncles and inflammatory dermatitis are also observed; while erythema, pruritus vulgaris, and gingivitis contribute their share to a very polymorphic symptom-complex. It appears that some of the lesions in rose-gatherers may...
be produced through the agency of one or other of the germicides—formol, carbolic acid, or sulphate of copper—used to destroy the parasites that threaten the life of the rose-trees. Others may be caused through the manipulation of manure. Careful attention to cleanliness and the prompt treatment of thorn-pricks with antiseptics are among the many small measures employed to protect the hands of the workers in this department of horticultural industry.

/Public Health Administration in Dublin.

Sir Charles Cameron has just published a booklet entitled "A Brief History of Municipal Public Health Administration in Dublin" (Dublin: Hodges, Figgis and Co.), which appears to be intended as a reply to the recent Report of the Departmental Committee on the Housing of the Working Classes in Dublin. Sir Charles gives a great deal of interesting information concerning the various activities of the Dublin Corporation, and shows that, whatever its failings, that body has accomplished much good work in the past half-century. It has brought a public water-supply into the city, it has established an efficient, if expensive, system of electric lighting; it has abolished the old system of storage of filth, and established water carriage of sewage; and it has substituted main drains discharging into the sea for the old sewers opening direct into the Liffey. Sir Charles states that the Corporation has accomplished in work which may be called sanitary, using the term in its widest signification. It is hardly, however, relevant to a charge of failure as regards provision of housing for the working classes and supervision of the existing tenements. A man will charge with stealing a sheep; it may be to his credit, but it is no defence to the charge, to prove that he did not steal the herd of cattle in the next field; nor is it much better to suggest that the sheep was not really full-grown, but only a lamb. Sir Charles attempts to minimise the charges with regard to neglect of proper control of tenements, on the facts referring to them. The facts remain, however, that the Corporation has neglected to enforce not only its own bye-laws, but the statutes, as, e.g., in regard to a register of tenements being kept, and, further, that rebates of taxes have been given, in some cases to members of the Corporation, on houses classed by the health department as " unfit for human habitation."

A Substitute for Antiseptics.

The evolution of scientific wound treatment forms one of the most interesting studies in the realm of therapeutics. In ancient times healing balms composed of various aromatic resinous substances were largely employed for wounds and sores of all descriptions. During the Middle Ages the influence of empiricism made itself strongly felt in this country, and, accordingly, the strange applications of crude animal organic matter, were used for a like purpose. With the advent of Listerism came the strong antiseptics, carbolic acid and bicloride of mercury. These had the desired result of destroying germs, but they frequently damaged the tissues so much that much of the inflammatory reaction in wounds was due to the irritating effect of the chemical disinfectants employed in their healing. The modern aspetic treatment of operation and freshly-incised wounds requires the use of no strong antiseptics to damage the tissues. A little pure tincture of iodine is applied directly to the line of incision, and that is all. Wounds that are septic from the first are on a somewhat different level. They require antiseptic treatment in some degree in the majority of cases. The use of Wright's citrated isotonic solution as a substitute for antiseptic solutions is spoken highly of by Dr. G. K. Dickinson, M.D., of New Jersey, N.J. (a). The liquid is applied to the wound by gauze kept well soaked, and its cleansing and healing properties speedily become manifest. It has been successfully employed as an irrigant in cases of vaginitis, septicaemia, endometritis, and also in infected wounds following operations upon the gall bladder. The use of this physiological solution has obviated the necessity for strong antiseptics during the two years in which it was tried in Christ Hospital. It certainly has the merit of being cheap, non-toxic, and harmless to the tissues.

PERSONAL.

Their Majesties the King and Queen visited the Royal Infirmary, the Western Infirmary, and the Royal Hospital for Sick Children, Glasgow, and the Royal Infirmary, Perth, during their Scotch tour last week.

Sir Watson Cheyne, Bart., Honorary Surgeon to the King, and Surgeon to King's College Hospital, has been elected President of the Royal College of Surgeons of England.

Dr. Herbert Stanley Birkett has been appointed Dean of the Faculty of Medicine in McGill University.

Sir Wilmot Herringham, M.D., F.R.C.P., has been re-appointed Vice-Chancellor of the University of London for the year 1914-15.

Mr. V. Zacharias Cope, M.D., M.S.I.ond., has been appointed Surgeon in Charge of the Orthopaedic Department at St. Mary's Hospital.

Dr. Thomas Chetwood, M.B.Lond., D.P.H.Oxon., has been appointed School Medical Officer and Deputy Medical Officer of Health for Sheffield.

Mr. L. E. Barrington-Ward, Ch.M., F.R.C.S.Eng. and Edin., has been appointed Surgeon to Out-patients at the Great Northern Central Hospital.

Sir Almroth Wright, F.R.S., M.D., D.S.O., will preside at the annual dinner of the older students of St. Mary's Hospital to be held in October next.

Dr. F. W. Craig, M.R.C., Ch.B.Edin., D.P.H., has been appointed Medical Superintendent of Health and Tuberculosis Officer for Londonderry.

Mr. A. H. Bostock, M.R.C.S., L.R.C.P., has been elected Honorary Surgeon of the Royal West Sussex Hospital, Chichester, in place of Mr. F. Skirle, resigned.

Mr. Duncan Matheson Mackay, M.D., C.M.Edin., M.R.C.S., L.R.C.P.Lond., has been appointed Honorary Ophthalmic Surgeon to the Hall Royal Infirmary.

The Honorary Degree of LL.D. has been conferred by the University of Edinburgh upon Dr. Byron Bramwell. Consulting Physician to the Edinburgh Royal Infirmary, and upon Dr. F. W. Mott, Pathologist to the London County Asylums.

Dr. R. Wallace Henry, the Originator, Founder, and First President of the Union of Medical Practitioners and the Leicestershire and Rutland Public Medical Service, has received the recipient last week of a handsome testimonial as a token of love and esteem from his professional colleagues.

(a) Medical Record, June 20th, 1914.
Mr. President and Gentlemen,—I thank you for the honour you have done me in inviting me to make these remarks to you this evening, and I only hope that you will not find what I have to say too trivial or too familiar to be of use. I propose to touch on a number of separate practical points, none of which are original; you must pardon me if you know of them all already, but I have found that even when things are known about they are not always made use of as often as they might be, and that must be my excuse for bringing them before you to-day. The reason for using the word "further" in the title of this address is that I have already discussed a number of similar points elsewhere, and although I should have liked to have mentioned some of those again to-night, I shall refrain from doing so, because they have been published in The Medical Press and Circular for May and December, 1912.

The first point that I should like to bring to your notice is THE VALUE OF HORSE SERUM AND OX BLOOD IN THE TREATMENT OF RESISTANT SIMPLE ANAEMIA.

Of course, the great majority of cases of anaemia are remedied easily by the ordinary simple treatment of rest in bed, the administration of one or other of the many preparations of iron with or without arsenic, steps being taken at the same time to ensure a regular action of the bowels. Six weeks in bed under this treatment will generally cure almost any case of chlorosis, however severe the latter may be to start with, especially if the room in which the patient is being nursed is a sunny one; but now and again one meets with a patient whose anaemia proves so refractory to treatment that none of the ordinary things seem to do any good at all. Rare though these cases may be, all of us meet with them from time to time, and the question arises as to what further kinds of treatment can be adopted. Both horse serum and ox blood may then be used, and sometimes with extraordinary benefit. The patient is generally an unmarried woman of the lower-to-middle classes, and she has been to see all kinds of doctors, and may have visited various spas noted for the treatment of anaemia. In one such case recently, for example, the lady was 33 years of age, and for over ten years she had been so anaemic that she had been unable to take any active part in life or in the doings of her brothers and sisters, and she was more than ever hopeless of ever being cured. Her haemoglobin measured only 35 per cent. of normal, there was no organic disease of any of the viscera, and yet all attempts to cure her anaemia had failed hitherto. Within two months of treatment by horse serum and ox blood her haemoglobin had risen to 65 per cent. of normal, her red corpuscles were over 5,000,000 per cubic millimetre, and she felt perfectly well. She may, of course, relapse, as so many of these patients do, but that does not altogether detract from the value of the treatment. It is carried out as follows: The patient is put to bed in a sunny airy room, with wide-open windows, and upon a full diet, including particularly the natural gravies from roasted meats. For each of eight successive days she is given a subcutaneous injection of 10 c.c. normal horse serum—preferably into the deep subcutaneous tissues of the abdominal wall; the serum is obtainable sterile and ready for injection in glass phials like those in which ordinary antitoxin is supplied, and sometimes possible to give a ninth or even a tenth injection, but the phenomena of anaphylaxis and severe serum reaction generally prevent more than eight doses being given, and one is in any case obliged to stop by the tenth day, because beyond this point the giving of more serum is actually dangerous on account of the anaphylaxis. The treatments should be warned previous to the beginning of the treatment that she will have considerable reaction, with pyrexia up to perhaps 102° F. or even higher, starting, as a rule, about the eighth or ninth day, and persisting or more or less, but not getting continuously worse, up to the seventeenth or eighteenth day if eight to ten injections are given. Three to nine or twelve injections are given; until this is past the patient should remain entirely in bed. During this pyrexic period she will feel more or less ill in herself, and will very probably suffer from urticaria, which is sometimes mainly local to the site of injection, but more often occurs all over the body. It has been recommended that calcium lactate should be given in 10 grain doses three times a day with the idea of minimising these serum phenomena, but in practice this drug is disappointing in this connection; 10 grain doses of aspirin given once, twice, or three times a day often alleviate the itching of the skin and the headache; locally one may duff on a lotion consisting of one part of carbolic acid and nine parts of water to each pint of which are added 2 tablespoonfuls of glycerine and a teaspoonful of bicarbonate of soda or some weak caustic soda. When the reaction is over, that is to say about the twentieth day from the beginning of the treatment, one can begin giving fresh delibrinated ox blood per rectum. If one could continue indefinitely with the horse serum one would so, but on account of the anaphylaxis a considerable interval must elapse before further doses of it can be given with any safety. The delibrinated ox blood, on the other hand, can be given without any danger, and continued indefinitely. It is obtainable by arrangement with any butcher who kills his own animals; he whirls the blood to delibrinate it, and pours it into bottles that have been sterilised by boiling, and places these on ice; the blood should be kept on ice until it is used. If fresh blood can be obtained each day this is best of all, but as a rule the butcher does not kill every day, and it may be necessary to arrange for a three days' supply at a time. A suitable dose is 8 ounces, and it is given like an ordinary nutrient enema with a rubber tube and glass funnel. The bowels having been well opened in the morning, the nurse inserts the small rubber rectal tube about six inches into the rectum, and the blood is allowed to run in through a suitable funnel held from two
percha tissue or jaconet of sufficient size to cover over the whole of the flannel when it is in position, also with two armholes cut in suitable positions. One mixes half a pint of brandy with a pint and a half of cold water in a washhand basin, and steep the large flannel in this until it is thoroughly wet all through; one just squeezes it enough to leave it quite wet but not actually dripping. When the chest is stripped, the flannel hot. If it is too wet, the base of the chest is applied over the flannel in the same way, the whole being kept on by quickly wringing a broad bandage loosely all round the chest and over the shoulders. Some patients to use the brandy and water hot. If lost, relief is obtained by using it tepid or cold, and doing so is no danger to the child, for very quickly the heat of the body, especially as the result of the increased amount of blood which the brandy pack brings to the surface of the chest, makes the application steaming hot, and in half an hour or less the child very often falls asleep peacefully. This, which may last for several hours, can have any coughing at all. Precisely similar treatment may be employed in some cases, but the most striking benefit is obtained in children, especially between the years of five and ten. Again and again one has seen a refreshing sleep ensue when up to the time of using the brandy pack all other remedies have failed.

The next point I should like to bring before your notice is the Value of Bicarbonate of Soda in the Treatment of Resistant Cases of Epilepsy (Grand Mal)....
to take any remedy that will help them to lose their fits, and most of them take the crude drug just as it is without any difficulty at all. It is less nasty when given as the plain powder than it is when an attempt is made to prepare it in mixture form. Two recent hospital out-patients have improved so much under the liborate treatment that they are given to one, whereas upon bromides they could get no employment at all, they are now back at permanent work.

The next point that I wish to draw attention to is the value of venesection in certain chronic conditions, especially arterio-sclerosis and polycthemia.

A period in the early part of last century when venesection was performed indiscriminately for six weeks to two months, is sometimes remarkable, and to this therapeutic measure fell into disrepute, so that it was seldom resorted to at all. There has, however, been a reaction in favour of it under certain circumstances, and most physicians do not hesitate to bleed patients suffering from certain acute maladies, especially uraemia, lobar pneumonia in its pleuritic, and acute heart failure from valvular disease or myocardial degeneration. It is, however, by no means only in acute conditions of this kind that venesection can do good, and the relief afforded to many persons suffering from arterio-sclerosis with greatly raised blood pressure by periodic venesection, say at intervals of a month or six weeks, has been found so beneficial that it is sometimes practised among those who are not suffering from acute disease. One of the objections to venesection in the past has been that it then meant incising the skin, and thus producing a wound which might become septic, and in any case amount to a dressing. Now, however, by means of short hollow needles, which are made for me by Messrs. Down Bros., it is quite a simple matter to puncture a large vein, say 15 or 20 ounces or even in one's consulting-room, the patient being able to go straight away to his ordinary duties after the little operation without a dressing upon the arm at all. The broad rubber bag that one uses in connection with a phymognomoneter is of great assistance in this connection, and it is not uncommon to have a patient get into it until one just obliterates the radial pulse. Having found the maximum sphygmometric in this way, one now lets a little of the air out of the bag until the pulse has returned, and in this way one has a very simple tourniquet in which one can regulate the pressure to a nicety, and one does not have to use one of the elastic tourniquets that rubber tourniquet so often used to be. Moreover, the broad band of pressure round the upper arm seems to impede the transmission of painful impulses from the nerves of the forearm to the brain, so that the patient feels less than one might expect when one inserts even a big needle into the distended vein of the elbow. Of course, to have a wide, short needle, for otherwise, if one uses a longer, narrower needle, such as one through which one gives a dose of antitoxic serum, after the first two or three ounces of blood have run out the flow gets gradually slower, and finally ceases from clotting in the narrow tube. It is an additional advantage to have a rubber attachable, so by means of it one can direct the blood into the measuring glass or other receiver more conveniently than one can straight from the metal needle itself. It takes from five to ten minutes to let out 20 ounces of blood from the vein in this way in an ordinary case of arterio-sclerosis. On releasing the air from the pressure bag the bleeding stops at once; after removing the needle a few drops may escape, but if the arm is now held vertical for a minute or two it is found that no further bleeding occurs, and the puncture hole needs no dressing whatever, though it may be wise to powder it a little boric acid. The patient goes to his ordinary work directly afterwards without feeling any ill effects; indeed, many ask to have the venesection repeated periodically because they feel so much better for some time after it. How the venesection acts it is not easy to say. I certainly do not do so by reducing the blood pressure, for the latter is affected by it in every little if at all; one imagines, however, that when a bulk of blood is thus removed from the vessels it is made good by absorption of other fluid in the tissue spaces; the latter in their turn require a fresh supply from wherever they ordinarily get it and thus there is an increased removal as it were for the time being. At any rate, there can be no doubt as to the beneficial results in actual practice it cases are properly selected. One sees the same benefits come about spontaneously from a severe epistaxis sometimes. Venesection with a hollow needle, with a phymognomonet bag for tourniquet, is so easy that I should like to see it used more widely, not in acute conditions only, but also in selected chronic cases of arterio-sclerosis, polycthemia, plethora, and high blood pressure.

To be concluded in our next.

Note.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture next week will be by Mr. E. M. D. Oxon., F.R.C.P., Physician to Guy's Hospital. Subject : Some Further Therapeutic Points.

ON THE VALUE OF THE BACTERIOLOGICAL EXAMINATION OF THE URINE. (a)

By T. S. KIRK, M.B.,
Surgeon to the Royal Victoria Hospital, Belfast.

I wish to call your attention to the value of the bacteriological examination of the urine. I do not pretend to be a bacteriologist, and though I am a clinician, and I will take the liberty of speaking of it from a medical as well as from a surgical point of view. The bacteriological work in connection with my cases has nearly all been done by Prof. Symmers and his staff.

Five years ago, when this work was commenced, the only cases so examined were cases of acute infections, especially those with multiple lesions. To-day I examine bacteriologically the urines of all my cases as a matter of routine. The reason I made this change was on account of the valuable results obtained in some of the early cases and on account of a disaster which might have been avoided by such an examination.

I will mention two of my recent cases as examples.

(a) Male, 61 years. When two years old he had a lumbar abscess, diagnosed as due to spinal caries. This abscess was opened, and it eventually dried up. When 25 years old he developed an abscess beneath his rectum and bladder; this was opened and drained and an external urethrotomy was done at the same time to drain his bladder. Later he had many small perineal abscesses. He had palmar psoriasis all his life. He had many patches of chronic eczema on his limbs and body; several times every year he had crops of boils on his face and neck. His hair came out, and he had much eczema of his scalp. He was unhealthy-looking and very thin. When I saw him he had chronic cystitis and a stricture of his urethra at the site of
his old urethrotomy wound and a peri-urethral fistula, as well as his skin affections.

From his urine many colonies of streptococci grew and a very few colonies of B. coli. He had altogether four injections of a streptococcal vaccine in the course of fourteen months, and his stricture was dilated. All his troubles were cured and he has had no relapse and no treatment since the spring of 1910.

(2) Male, aged 25 years. I saw him on account of an abscess of his left hip joint. Twelve years previously he had an attack of acute pneumonia. I found he had a small abscess in the lower lobe of his right lung. This abscess was opened, and from it a pure culture of pneumococci was obtained. The same micro-organism was found in his urine. When I saw him last he had been ill in a military hospital and was very much emaciated. He got an autogenous pneumococcal vaccine, and in a short time all his general and local signs and symptoms disappeared, and he is now in excellent health and able to get about with an ankleless hip joint.

These two cases, I think, showed accurately in the best cases of the infections from which the patients were suffering, and the results seem to show that the vaccines made from the urines were of undoubted benefit.

The next class of cases in which I found this method of examination of value was in cases of skin-grafting of large ulcers. For many years I have been much interested in the skin-grafting of burns, and have tried many ways of preparing the grafts for the grafts and many ways of treating the grafts after the operation, and I have always had much uncertainty as to whether the grafts would take or not.

Now I have found that some patients with large ulcers have micro-organisms in their urine and other urines. The patients with sterile urines can be grafted, and if a careful technique in cleaning the ulcer and getting rid of all granulation tissue, etc., is carried out, the grafts will take in every case; but if the urine contains infective micro-organisms, a good result can only be hoped for if the vaccine treatment is carried out before and after the graft and even then some suppuration nearly always occurs.

This relation between the character of the urine and the result of skin-grafting has been quite constant during the last eighteen months. A similar relation exists in cases of varicos veins and the operation for varicos veins, and explains, I believe, why operations for varicose veins in patients with varicose ulcers frequently suppurate. The same relation is present in patients suffering from boils or acne. Some of these patients have staphylococci in their urine and others are sterile, and this explains why plastic operations in such patients sometimes suppurate.

This case also made me decide to examine all urines bacteriologically was the case of a child with a fractured femur, in whom the urine was not plant out before operation.

This child had an oblique simple fracture with two inches of shortening. He was an anaemic, sickly-looking child, with a history of digestive disturbances before the fracture. It had no definite focus of inflammation anywhere. I operated on the femur and closed the wound with continuous layered sutures without any drainage. Four days after the operation the child was very ill and feverish. The wound in the thigh looked all right, but I opened it and got some serum with flakes of lymph in it, and from this serum there grew many colonies of the B. coli, and the same bacillus also grew from his urine. Happily he made a good recovery. I feel certain that in this case the child's previous ill-health was due to an infection of B. coli which had become chronic, and would probably have been detected by a urinary examination.

Since this occurrence I have planted out all urines as a matter of routine, and the value of the procedure from a general medical point of view has been demonstrated.

In the beginning of last December I saw a patient who was supposed to have malignant disease of his spleen. The spleen was hard and enlarged to a couple of fingers' breadth from the umbilicus. He had a small amount of fluid in his peritoneum. Two years before I saw him he had commenced to feel weak and lose flesh. At that time he noticed small boils on his legs and a few on his back and neck. Three weeks before I saw him he had a mild attack of left-sided pleurisy. A blood count showed a moderate degree of secondary anaemia. His urine was planted on blood agar and a copious growth of Staphylococcus citreus appeared inside twelve hours. Dr. Wilson had made a vaccine from this growth, and about six weeks ago was told that he was at his work again and feeling quite well and that his spleen had gone down in size. This patient had no other treatment, except the vaccine, and his improvement was so rapid and marked that it is hard to think that the vaccine was not the cause of his improvement.

Last year I had a number of cases of empyema under my care. There were two due to a pneumococcus, one due to the B. coli, three due to a staphylococcus; in two of the latter there were staphylococci in the urine, all the others had sterile urine. Those with sterile urine got better much quicker than the others. In fact, one of those with staphylococci in the urine has not been improved at all in spite of vaccine and other treatment.

The bacteriological examination of the urine may, therefore, be of use, not only as regards diagnosis, but also as regards prognosis. In January last year a young man was in my ward who had a simple fracture of his ulna, and I was in charge of the dressing of his ulna, and the removal of the plaster a month later. The patient was well, and I was to remove the plaster the following week. I thought the wound would suppurate and asked the medical officer to remove the plaster. Unfortunately, I am going to blush at the memory, because when I went to remove the plaster I found there wasn't any wound to remove. The patient had a scarred condition of his skin, and his urine contained many staphylococci, and these were not affected by the dressings and by the application of the plaster. I should have removed the plaster, but the wound was already under an anaesthetic, although I tried to do so twice. The question of reduction by operation had then to be considered. This patient had a scaly condition of his skin, and his urine contained many staphylococci, and these were not affected by the dressings and by the application of the plaster. Consequently, I refused to operate on him, as I felt sure his wound would suppurate. While I was ill last year, a colleague, whose aseptic technique is above suspicion, operated on him, and was disgusted to find that the wound suppurated. Thus the result anticipated from the condition of his ulcer actually occurred.

I think I have tried enough cases to prove that examination of the urine is of undoubted value in many cases, although it is still only on trial. I do not say that it is an infallible guide to the nature of an infection. Unfortunately, I have come across cases of infection with many suppurating foci, in which nothing has grown from pus, blood, or other body excretions bacteriologically. Now, to make this generally possible, some simple method, which any medical man could practise, must be...
devised, and cultures from the urine are at present the easiest and quickest to make, and, therefore, we must try to get a reliable method of examining the urine.

Such bacteriological examinations of the urine are of especial importance in cases of injuries and operations, and I hope we may soon have some simpler and sure way of detecting the presence and nature of infective micro-organisms in our patients, and thus providing the complement to Listerism. In Listerism, as practised to-day, every precaution is taken to prevent the entrance of micro-organisms into wounds, but no cognisance is taken of those in the patient's system, and it is for this reason that we find so many unaccountable cases of infection following aseptic surgery, and why they all every now and again break down. It is a well known fact that blood infections cause suppuration in haematoma and other injuries unaccompanied by any external wounds, and there is no reason why a similar infection should not play havoc with operation wounds.

THE TREATMENT OF LARYNGEAL TUBERCLE.

By W. PERNWELL. M.D., LONDON, F.R.C.S. ENGL.,

Laryngologist and Otologist to the Royal Southern Hospital and the Southport Infirmary, Lecturer on Laryngology, University of Liverpool.

I question if the profession is aware generally of the extreme frequency of tubercular disease in the larynx. Except in the rarest instances, it is now settled that it is always secondary to pulmonary tuberculosis; large series of post-mortem examinations show that in fatal cases of pulmonary phthisis 50 per cent. are complicated by deposit in the larynx. As to its frequency in living patients, it may be said that in the first stage of phthisis about 10 per cent. have laryngeal complications, while in the third stage that figure rises to 72 per cent. What is this frequency not more generally recognised?

First, because the larynx is seldom examined. Secondly, because disease there may exist for a considerable time with no noticeable symptoms. Thirdly, because the pulmonary disease is much more insistent, and gives rise to more marked effects. But, as it is frequent, the question becomes important: Can anything be done, apart from sanatorium treatment, to cure or relieve it? (a) In 1880 Morell Mackenzie said: "The prognosis of laryngeal phthisis is always extremely unfavourable, and it is not certain that any cases ever recover." To-day there is no longer any doubt that cases do recover. I myself have seen them recover, and remain well for many years, in one case for eighteen years. Records show the same thing, and Heryng has published post-mortem records which establish clearly the cure of cases as the result of operative treatment. Given an early diagnosis, I should say that the prospects of cure depend on three factors: (1) local treatment; (2) the degree of pulmonary disease, and its general effects on the organism; and (3) the possibility of sanatorium and other hygienic measures. The prognosis must depend, of course, on the degree of local involvement, but it is not always the slight cases which do best; marked thickening from tubercular deposit and extensive ulceration will clear up in a striking manner. The real factor of prognosis is, and must remain, the course of the pulmonary lesion and its adequate treatment.

Conversely, the prognosis of pulmonary phthisis depends to some extent on the coexistence or not of laryngeal complications. It is well known that sanatorium superintendents are very shy of taking in laryngeal cases. The irritable cough of laryngeal tubercle interferes with rest; all laryngeal cases are easily depressed; and the local disease has dangers of its own. All this ought not, however, to exclude laryngeal tubercle from sanatorium treatment. A wise and constant effort should be made to take them into those sanatoria only where in the first place there is a trained laryngologist to deal with them, and where in the bulk of cases laryngeal symptoms are the most prominent. Also, by a trained laryngologist I do not mean a man who is only just able to examine a larynx, but one who is thoroughly familiar with the whole of laryngeal surgery. This digression will perhaps be pardoned, if only because it accentuates the almost constant association of tubercle of the larynx with pulmonary tubercle.

Speaking generally, therefore, I would say that if the case is one which is favourable from the point of view of the lung, it is also favourable from the point of view of the secondary laryngeal disease, if only that disease receives appropriate local as well as general treatment.

What, then, is the local treatment?

Special opinion has gone through many phases in my time on this as on every other subject. When I began practice, the routine treatment in tubercular ulceration was painting with lactic acid. This caustic was supposed, rightly or wrongly, to have a selective effect on the tubercular deposit, and to spare the healthy parts of the larynx. Accordingly, after anaesthetising the larynx by cocaine, we used to rub in the pure lactic acid, and we were especially told to rub it in with force. This was not a pleasant process for the patient, but in some cases it undoubtedly had marked effect in promoting healing of tubercular ulcers. The after pain, however, was considerable; and therefore some weak-minded practitioners thought that as much good might be done by the repeated spraying of the larynx with a dilute solution of the drug. My experience, and I think that of all others, showed that it was useless—and worse than useless, even irritating. Just as painting a granular pharynx with nitrate of silver in 50 grammes solution only irritates, while the galvano-cautery cures, so was it with a solution of lactic acid in laryngeal tubercle. The pure acid, however, was, and is, extremely valuable. I can recall one case of ulceration of the vocal cord which healed up under lactic acid and remained healed for twenty years.

For cases which were not ulcerated, but where there was marked pseudo-cord, mental and other like aromatic sedatives dissolved in paraffin were slowly trickled into the larynx from a laryngeal syringe. I cannot say that I have ever seen any good effect except the relief of cough and irritation. But lactic acid and menthol were then our main remedies.

The next stage was the advent of severe surgical measures. Krause, and Heryng of Warsaw, introduced into practice the laryngeal curette. Sets of instruments came into our hands, biting instruments, scraping instruments, and cutting instruments like cutting bone forceps. The interior of the larynx was vigorously attacked with these. Ulcers were scraped, just as on the ulcer of the leg is scraped, elastic tissues were ablated, diseased cartilaginous cartilages were cut out bodily, and the larynx was treated generally as if it were a tuberculous knee-joint. There is no doubt that wonderful results were obtained, in tolerant patients. But I doubt whether our English patients were tolerant enough for this process. It had to be repeated; it
produced sometimes—though not always—marked local and general reaction, and not uncommonly severe haemorrhage; and, of course, in spite of local anaesthesia, much pain. Still, it was a rational treatment, and in good hands and in good cases cured the disease. Like every other surgical treatment, if only feebly applied, it, on the contrary, did much harm and hastened death.

Of course, the one trouble always was, that when you had got your ulcers cleaned up, they were always liable to re-infection from the pulmonary discharges; and the huge open wounds resulting from the treatment were particularly liable, unless they healed up quickly, and their cure, at any rate for the time, resulted. Speaking generally, the method was not largely used in England, but it was very extensively used in Russia and Northern Germany, where apparently there is no limit either to the enthusiasm of operators or the tolerance of patients.

The same development of sanatorium treatment of consumption; and laryngeal tubercle shared this movement with pulmonary tubercle. The great principle in the treatment then became the proper regulation of food and exercise, combined with fresh air, and, above all, absolute rest of the voice. It is, of course, impossible to secure complete rest in these days of noise and muscle, which is, of course, forbidden, and by prolonged general reposed violent respiratory movements were prevented. Cough also received special sedative treatment to secure immobility of the larynx.

There can be no doubt that this method often secures brilliant results. There is at least one well-known laryngologist who has had many ulcers completely cured of laryngeal tubercle by this means: and it offers today in sligh cases the best chance of success.

But in the last few years, there has been introduced a means of treatment which gives most valuable results. That is the use of galvano-puncture.

The rationale of it is not so much the actual burning away of diseased tissues, as the fact that the hot platinum point has a local destructive effect on the bacilli, and that by promoting fibrosis it tends to limit the spread of the disease. That at any rate is the theory. In practice it is performed by puncturing diseased areas by a fine heated point which is thrust down to it is among the healthy tissue. The point must be almost at a white-heat: several punctures are made at the same sitting, and an interval of three weeks or less secured between the applications. Two things are surprising: one, the small amount of inflammatory reaction or subsequent pain; the other, the rapid shrivelling-up of inflations under its use. Whether it is applied under the guidance of the laryngoscope, or through a direct laryngoscopic tube, matters nothing. Each operator will use the method he is most at home with. Of the result, however, in many cases there can be no doubt.

There is one special part of the larynx which, when alone affected, can be easily removed. That is the epiglottis. It is not a very common seat of the early deposit of tubercle; but it is not seldom affected. When it or a part of it is affected there can be no question that it, or the diseased part of it, should be amputated with a powerful cutting forceps. Considerable portions of it can be removed with no effect on swallowing except a good effect, and the operation furnished a rapid and easy way of getting rid of the stroke, of a large amount of diseased tissue.

It would seem that when once the desirability of free surgical attack on the tuberculous larynx is admitted, the question of thyrotomy and radical treatment after naked-eye inspection would be the next step. Unfortunately, the results of thyrotomy are, or have been, on the whole bad. A few cases have been recorded in which the disease has been cured; but factors against success are (1) the co-existing lung disease, which renders the patient peculiarly unfit for external operations, (2) the fact that infection is apt to attack the wound. Cases suitable for thyrotomy may be a few (1) those with localised tuberculomata, (2) those where there has been perichondritis and necrosis of cartilage requiring removal of the dead cartilage and drainage. On the whole, it seems that as much good, with less risk, can be done by suitable intra-laryngeal surgical treatment as by thyrotomy.

Tuberculin has of course been tried. It might be thought that the larynx offered a good field for testing tuberculin, as the effects could be observed accurately; and that is true. Unfortunately, the results are not by any means always beneficial. Dr. C. Mac Wilkinson was able to describe, three years ago, several cases which had been completely cured, and he concluded that all other methods of treatment were obsolete. That has not been the experience of many other observers. It may be that Dr. Wilkinson—who of course discards the opossum index, and uses methods of his own—may have some special knack or acumen which enables him to get results others cannot get. I should be inclined to say that on the whole the effects of tuberculin are disappointing, and certainly not so uniformly good as to render other treatment unnecessary.

To sum up, in conclusion: What are the proper lines of treatment of tubercle of the larynx?

(1) The treatment of the lung disease by sanatorium methods.

(2) The prescription of absolute rest of the voice, and as much rest of the respiratory movements of the larynx as is consistent with proper treatment of the lung.

(3) The provision in sanatoria of properly trained laryngeal surgeons.

(4) Possibly the establishment of sanatoria devoted exclusively to the treatment of tuberculous cases complicated by laryngeal disease.

(5) If there is thickening by deposit, or by the pseudo-exudative condition of the various folds of membrane in the larynx, the repeated application of galvano-puncture.

(6) In cases of slight ulceration the vigorous application of lactic acid, possibly combined with formalin.

(7) In cases of extensive disease removal by intra-laryngeal methods of the diseased structures, but only in cases not suffering too severely from the general effects of the pulmonary trouble. In particular, the removal of diseased parts of the epiglottis can be undertaken with ease and safety.

(8) A trial of tuberculin by skilled and experienced hands.

All these methods will often fail; but it is none the less true that in early cases, and in particular in cases which have a fair amount of resistance to tuberculosis at any rate either natural or acquired, the results of treatment will be found strikingly favourable, and not seldom permanent.

Mr. Thomas John Hitchens, M.R.C.S., L.R.C.P., D.P.H., late of 42, St. Aubyns, Hove, formerly of Broadfield, Crawley, Sussex, and Surgeon to St. John's Hospital for Diseases of the Skin, London, left estate of the gross value of £6,531.
PREHISTORIC MAN AND HIS EARLY EFFORTS TO COMBAT DISEASE. (a)

By T. Wilson PARRY, M.A., M.D.CANTAB.

Part II.

It must have been but a short step for the first man who, firmly believing in demontical possession, and at the same time suffering either from frequent fits, severe pain in the head of a periodic or paroxysmal nature, chronic hemi- or unbearable Ménière's disease, made an effort to free himself from his fetters. Life had become an intolerable burden to him, and he believed that there was a devil inside his cranium that was petitioning somewhat persistently for liberty. Was there not the Medicine-man who always attended to members of his tribe when accidents befell them, who stopped their bleeding and dressed their wounds? He would go to him and ask him to make a hole in his skull to let out this wicked and restless spirit. The first operation must have been troublesome and tedious, not to mention its extreme danger. The scalp had to be cut through with a sharp point of flint or obsidian, the bleeding stopped, and the scraping of the bone commenced. This would take the first operator many hours to perform, but the patient was helped and anxious to get rid of his devil and possessed that unshackling stoicism to pain that is characteristic of the savage and the operation would be at length completed. If the patient recovered, whether he obtained relief from his symptoms or not, he was henceforth revered as a sacred person. We can thus see why, in some districts, trephining was so prevalent, for prestige seems to have been purchased by undergoing this operation. After death the skull was eagerly sought after. The trephined portion was removed by flint saws, and pieces of bone, edged by part of the healed cicatrix, were removed. A hole was bored through the centre of this trophy, and it was henceforth regarded as a talisman that it worn would insure the wearer from getting the disease from which the opiatee had suffered. So great a demand appears to have been made for these amulets, at one time, that we actually find spurious imitations were made from untrephined pieces of bones, so that a portion of the healed cicatrix became an essential to prove its authenticity. The year 1868 was a memorable one, for it was in this year that M. Prunières discovered in a dolmen near Aliguières the first trephined neolithic skull to which the attention of scientists was drawn. A large piece of bone had been removed, and the smoothness of the edges made the discoverer think that this had been purposely polished for the lips, in the converting of the skull into a drinking-cup, a practice well recognised among savage tribes. The finding of five other skull fragments, in the same dolmen, all partly removed in the same way, made the finder think that these also were parts of converted drinking-cups. The interpretation of this mystery was left to Professor Broca, who showed indubitably that the holes in the skulls had been made during life, had been done by scraping, and that, after the death of the individual, portions of such skulls had been evidently eagerly sought after. He came to the conclusion that the operation was usually performed on children and from what he says: (b) "it could be effected on the skull of a child less than five minutes, whilst on an adult it would take an hour,"—it will show he had probably made some careful experiments. Broca believed that the operation was performed for the cure of epilepsy and convulsions, and he argues from the supernatious practices found in connection with it that at that period, as well as long subsequently, these diseases were regarded as peculiarly the work of spirits.

He quotes from a treatise upon epilepsy (c) by Jehan Taisil published in 1603 not only to show that infantile convulsions were confounded with true epilepsy, but that, at that time, epilepsy and kindred diseases were looked upon as spiritual diseases, the works of gods or demons, while the remedies recommended in the treatise were highly in accord with the suppositious ailments. He says: "The skull, for example, applied to the crown of the head, sometimes the same administered in potions or pilules, and sometimes as nodules to be worn round the neck; while sometimes also scraping the skull was recommended. Broca goes on to show that (d) "all through the middle ages, and even after the Renaissance, the substance of the skull was used in the treatment of epilepsy, the skulls of Egyptian mummies being regarded as the most efficacious whilst in the last century all the pharmacists contained a bottle labelled Ossa Vermiliana for the treatment of epilepsy, the peculiar efficacy of the triangular lambdoid bone consisting in its form, which resembles that of the amulet cut from the human skull, thus showing the step between prophylactic and mystic medicine." Broca thought that the trephining was in accordance with the entire Neolithic Period on account of the fact that trephined skulls had been found in the cavern of the "Homme Mort" (Lozère) which dates from the commencement of the Neolithic Period.

It might have been thought, considering the number of trephined skulls that have been excavated in France, that the custom would have spread to the British Isles, as only the Channel separated the two countries, and we have evidence that there was no inconsiderable traffic between them in Neolithic times. I have only been able to hear of three such skulls that have been unearthed in this country, and I should be most happy if any of any other specimens would kindly inform me. The three specimens of which I know are: (a) A skull that was
dredged from the bottom of the docks at Port Talbot, South Wales, in or about 1870-2. I have a photograph of this skull to show you this evening, kindly lent me by Mr. Thomas Gray of the above-mentioned place. This skull shows a frontal excavation over the right supra-orbital region. Not having seen the specimen I am unable to give any opinion. (b) An interesting specimen showing a ring-trephine as if an effort had been made to remove a rondel of bone. This skull, which I have also here for your inspection this evening. It will be seen from the above that it is probable that two out of these three trephined specimens are of prehistoric age. I am able to describe them in this paper. In three of these specimens a complete perforation has been made in the cranial bones, and in the remaining three either part of the outer table alone, or the outer table and diploe have been removed by scraping. One, a male, from New Britain (presented to the Museum by Dr. C. G. Seligman), has a large hole measuring 28 mm. by 34 mm. in the right occipito-parietal region. The outer edge of this hole is thin, bevelled and smooth and shows a healed surface, demonstrating a successful operation. Of the five other skulls, all of which come from New Ireland and were presented by Dr. W. E. Redman, of Pictou, New Zealand, one specimen shows a rondel, on the left side the outer table has been completely rubbed through, and on the right is a circular scraping through the outer table leaving a boss of bone in the centre, which looks as if an attempt had been made to remove a small rondel of bone. Why these two operations should have been made on the same skull and both in the frontal region is difficult to imagine, unless the symptoms for which the operation was performed, having still persisted, a second operation was demanded. In the third skull there is a beautifully rounded hole measuring 14 mm. by 15 mm. in the left frontal region. The edges of this hole are smooth and rounded and show an excellent healed surface. The reason for the operation having been performed in this case is obvious, as there is a diseased patch of bone with considerable erosion in the mid and right frontal region. The devil had need of being released in this instance as the disease is undoubtedly of syphilitic origin. In the fourth skull there is a large patch of osteitis.
skull. It is not surprising, therefore, to find that the surgeon advised, or the patient solicited, the trephining of a patch 17 mm. by 28 mm. in front of this diseased surface, as probably a direct counter-irritation to relieve severe and continuous headache. The skull has not been perforated, but the outer table has been scratched through and the surface is smooth and shows every sign of healing. In the fifth skull there is a large elliptical scraping, measuring 48 mm. by 35 mm. in the right parietal region. There is inflammable material, such as touchwood or dried leaves being in the near vicinity for catching the spark. With a sharp point of some hard material it was used for drilling holes. In a clever prehistoric romance, entitled "The Master Girl," the bow-drill is shown most reasonably to have been invented previously to, and to have given the first idea of the ordinary bow, from which arrows are shot. Obsidian I also used in two ways. First, as obsidian flake scrapers, and secondly, as hafted implements in the form of an Admiralty Island knife. I used two kinds of sharks' teeth, both being hafted in wooden handles. A small variety, which I only employed in the case of an infant's skull, I obtained from a socketed club made by natives of King's Mill Islands; this specimen has been identified by Mr. C. Tate Regan, of the Natural History Museum, as belonging to "Carcharias glauces or a related species," while the larger specimen, which I used for two adult skulls, as Galeocerdo arcticus. The shells I employed were beach-worn specimens of a species of the oyster (ostrea edulis) picked up on the north coast of Brittany. For slate I used an ordinary piece of slate, shaped like a scraper.

For scraping a hole in bone, metal not being considered, there can be no better natural implement than a well-flaked piece of flint. Where flint cannot be obtained, as in volcanic regions, such as the South Pacific Islands, obsidian makes a good substitute. Obsidian is a natural volcanic glass, and can be flaked, in the same way as flint, by a sharp well-directed blow. The obsidian I used came from the Lipari Islands, north of Sicily. Contrasting these two substances I would give flint the first place. A hard, sharp edge can be obtained in flint which is more resistant to counter-pressure than is obsidian. Obsidian, like glass, can give an even sharper edge than flint, but it is much more brittle, and if care be not taken minute particles may swiftly penetrate into the eyes of the operator. I may remind you that while flint is a silicious sedimentary deposit, obsidian is of igneous formation. Both flint and obsidian when freshly flaked are excellent substances for surgical purposes. Both by virtue of their smooth surfaces, and here obsidian would take the pre-eminence, are aseptic, and this is a point of infinite importance when coming in contact with the dura mater. It

![Fig. 11.]

Dry specimen (female) trephined by hafted obsidian knife (Admiralty Islands) (Fig. 11). Rondel removed and can be seen below specimen. Time taken 78 minutes.

A deep furrow in the centre of this scraping which shows one the method by which it was done. It is all but perforated. In the sixth and last specimen there is a large perforation, 23 mm. by 40 mm., over the left frontal region and part of this hole is filled up with fresh callus that has evidently given a very successful result. All these cases, I have not the slightest doubt, were done by scraping the bone with obsidian flakes. The usual custom in Melanesia after the operation has been performed is to replace the scalp, which was incised in the first instance by an obsidian knife, and simply bind it in position by a bandage made of banana-fibre.

Being anxious to ascertain how Neolithic man trephined living subjects with the crude materials at his disposal, I made a series of some 19 experiments both upon recent and dry skulls. When showing the results of some of these experiments to Professor Keith, he informed me of a (7) pamphlet by Dr. Lucas-Championniere, in which I would find that several of my experiments had already been done by him. I was quite unaware of this brochure when making my tests. Referring to this pamphlet, it appeared to me that Dr. Lucas-Championniere had only experimented with flint. I experimented, in addition, with obsidian, sharks' teeth, shell and slate. I used flint in two ways, first in the form of neolithic scrapers, and secondly, as a hafted sharp point to a bow-drill. The bow-drill, I may mention, is one of the oldest forms of mechanical contrivances. Without any hard material affixed to its end it has been used from time immemorial by the Sioux and Canadian Indians to make fire by the friction caused when used against another piece of wood, some easily
surprised me at first, in no small measure, to find how cleanly and easily a flint knife can cut through the scalp, and obisidian, of course, is even better, for, in the Andaman Islands, in the present day, the natives shave their heads with obisidian knives. The method I employed for scraping the trephine-hole in both flint and obsidian was the following:—Having selected a site on the skull and also a suitable flake, I scraped as nearly as possible along a single line. This line I gradually converted into a groove, which soon showed two more or less prominent edges. The outer table of the skull is by no means as easy to remove in this manner as might be expected. As the groove progressed to the inner table the groove with a curved movement of the scraper till a depression was produced in the bone which gradually assumed an elliptical shape. It is only now a question of time and manipulation to convert this elliptical depression into a circular one, and then, having penetrated the inner table of the skull, to expose the dura mater and insert between them with the bone to the size and shape required. In only one case can I remember slightly bruising the dura mater, and the reason of this was that my supply of neolithic implements was limited and I had not to hand, at the moment, the particular shape I required. It must be remembered that when Neolithic man was operating by the hand he bountifully supplied with probably hundreds of sharp, newly-cut flakes, and immediately one became blunted or was not to his fancy in any other way, he would naturally fling it aside and choose another. As regards the bow-drill, I got my carpenter to affix a neolithic flint-point into a wooden shaft, and then worked a hole of the size fifteen in number, in a circular manner on the place chosen. These I enlarged till they touched one another. At this point there is a great risk of shattering the flint-point or of unhafting it altogether, as it strikes with force the broken edge of an adjoining hole. Having completed the circle with as deep holes as is expedient, I next fitted the edge of the flakes to them with the sharp and strong flint-flake, and then, by means of scraping and scraping, eventually removed a complete ronde of bone. This is an extremely tedious and clumsy operation and not in any way calculated to bear comparison with the simpler method of scraping. As regards sharks' teeth as scrapers, I could not compare the sharpening of a bone by them with the scraping of a flint and obisidian. It is no more excellent natural implement for boring holes in bone than a hafted shark's tooth. Its keenly serrated edges and its strong, sharp point make it an instrument invaluable to the primitive surgeon. It, moreover, possessses a natural flange which converts it into a trephine of undeniable utility, for the flange is so placed as to prevent the prying out of the trephine by the dura mater, or the bone to the wounding of the dura mater. A ring of holes (as in the case of the bow-drill) packed as closely together as possible, followed by the breaking down of the bridges between them by a scraping and saw-like action of the implement makes a hole, after removal of the rodel and obisidian, not unlike a new trephine the user could wish. Trephining by shell was probably never attempted by Neolithic man in Europe, though primitive man most certainly used shell-knives for ordinary use and shell-langets for opening abscesses in the South Pacific Islands. It took me about 25 minutes to trephine the skull of a 15 months old child, which took a quarter of an hour. During the scraping process the shell, of course, wears badly, and there is much more detritus than in the case of flint or obsidian. One specimen I experimented upon with slate. Slate has been found in many neolithic tombs, and it was doubtless used for domestic purposes, as the patting of butter or the making of cheese. I am quite convinced it was never employed as a trephine, for it is too soft and friable; but I made this experiment in order to test the value of slate as a boring implement as regards bone. It took me nearly 50 minutes to make the small hole I was able in the skull of a man 41 years of age. Subjoined is a list of my experiments. The originals are exhibited in the Historical Medical Museum, and I have to thank the curator, Mr. C. J. S. Thompson, for the loan of the trephined aboriginal skulls I am able to show you this evening.

We have been looking back to-night into the far-away past and have been endeavouring to piece together the history of prehistoric man from specimens of his handiwork that have been heirloomed to us by the sheltering hand of Nature, who has protected them for us, either by covering them over with the debris of rock or hiding them in the crevices of many a stony cavern. To this has been added a passing glimpse at the methods of present-day primitive tribes. Tylor says (19) "The uniformity which so largely pervades civilisation may be ascribed, in large measure, to the uniform action of uniform causes." Thus it is that the combination of these two parallel studies enables us to get a true insight into the life of prehistoric man, a century and a half away from us. We have been looking back upon these days as we now look back upon the opening years of the last century, will state that radium had only just been discovered, electricity was only used in a limited manner, and that scientists of that day were only then wresting hypodermism from the hands of the shrewd and clever charlatan. They will possibly look back upon these days as we now look back upon the opening years of the last century, and say that men of that day were shrewd and clever charlatans. They will possibly look back upon these days as we now look back upon the opening years of the last century, and say that men of that day were shrewd and clever charlatans.
TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

MEETING HELD THURSDAY, JULY 2ND, 1914.

DR. W. S. A. GRIFFITH in the Chair.

SPECIMENS.

Dr. H. R. Andrews showed a uterus which he had removed after performing Cesarean section. Labour was obstructed by a carcinoma of the cervix which had extended into the body of the uterus, but had caused no symptoms. The patient was 37 years old, and was admitted to the London Hospital on March 1st, 1914, having been in labour about 24 hours. On admission the pains were strong and frequent. The cervix was rigid and only two fingers dilated. More careful examination of the cervix found it to be extremely hard and firm feeling, as if a portion of a thick rubber ring pessary had been left in the tissues of the cervix on previous section. The posterior one-third was normal. There was no ulceration, but in front and to the left a raised, elevated edge could be made out. On examination with a speculum it was impossible to diagnose that it was by its appearance, but a sound sank into the tissues about half an inch with only gentle pressure. Cesarean section was performed and the uterus then removed. The anterior wall of the cervix above the growth was so thin that it tore in separating it from the bladder. On examination after the operation a hard, white growth was found to occupy all the lower portion of the cervix except a little more than an inch posteriorly. Sections showed squamous-celled carcinoma. The cervical canal was so diffusely involved that it was impossible to determine the area of the growth by its appearance. Sections showed a growth consisting of squamous epithelium. It was impossible to determine whether the glands were malignant or not. The incision into the area of the growth was made at the upper part of the cervix. There was no ulceration of the cervix itself. A diagnosis was made that the patient was suffering from a cancer of the cervix extending into the uterine cavity. Fortunately the patient did well for a time, the growth recurred, and the patient died within the year. Sections of the growth proved it to be a carcinoma, partly squamous and partly cylindrical-celled in type. It apparently arose from the interior of the cervical canal.

Dr. Macnaughton Jones showed a specimen of adenocarcinoma limited to the stump of the uterine cavity. The uterus had been removed from a patient, aged 44, a widow. She had had four children. For some years she had a vaginal discharge which was coloured but not offensive. The uterus was curetted, and the material removed was reported to be adenocarcinoma. Ten days later the uterus was removed, and at the operation the fundus of the uterus was found projecting into the uterine cavity and involving the myometrium. The growth was an inch and three-quarters in length. It exhibited the ordinary features of an adenocarcinoma.

The Practical Surgery (18) W. S. A. Griffith showed a case of utero-rectal adenomyoma with extensive decidual metaplasia complicating pregnancy. The patient was at 37 years old, married 15 years, one child, born December, 1890. Pregnant again at about the sixth month. On regular period of labour had been seen on September 22nd, and on the 26th the patient was admitted to the Maternity Hospital. On admission was in active labour, and the pains were increased. The patient was then examined by Dr. Andrews, who found the cervix extended above the myometrium, and on its anterior surface was a flat sessile fibroid. There was some hydranromia. The mass in the recto-vaginal septum was ill-defined and soft and spongy in character, not bleeding on digital examination, but on exposing it with a Sims' speculum and touching it with dressing forceps free arterial hemorrhage followed. The mucosa of the rectum was not invaded. A fragment of the growth was removed through the posterior fornix for examination. Adenocarcinoma was diagnosed. The test for decidual metaplasia was faintly positive. The optical test was not done owing to insufficient material. During the following month the case was carefully watched, and it was finally decided to perform a Cesarean section. In performing the operation the recto-vaginal septum was considerably, compressing the rectum and extending on the right side as far as the sacrococcygeal synchondrosis. It was decided to try the effects of radium, and this was done, 100 mg. of radium bromide being inserted into the middle of the growth, and two other tubes containing 37 mg. of radium carbonate and 50 mg. of radium bromide, for 20 hours. In June the patient was in good health and the pregnancy apparently was complete. Locally the utero-rectal mass had diminished considerably. Nothing further was done, as it appeared that there was a good prospect of spontaneous delivery. Sections of the growth stained by Van Giessen's method show large masses of typical decidual cells in a stroma of muscle and connective tissue. Within each mass is a cleft, lined by a thin lamina composed of flattened epithelial cells. In one part is a dilated gland tubule lined by low cubical epithelium and completely surrounded by large decidual cell groups. The growth was advancing slowly, and the section showed evidence of recurrence. It was thought that the decidual change supported the view that extravesical uterine adenomyomata were of Müllerian origin.

This paper was discussed together with that of Dr. Archibald Leitch on migratory adenomyomata.

Dr. Archibald Leitch communicated a paper on migratory adenomyomata with epilobiascopic demonstration. It was not uncommon to find parametrical tubes and stroma penetrating for some considerable distance into chinks in the musculature of the uterus where the organ was approximately normal, and in this way adenomyoma started. In the adenomyoma the glandular and connective tissue of the endometrium and the characteristic parts of the tumour was easy to establish; but sometimes the point of entry of the endometrium was restricted and the connection was difficult to find. Further, extravasinal adenomyoma there was no association between the two, but their histological identity with the former group left little room for doubt that they had migrated from the endometrium. They might be found as subserous pedunculated tumours, or, better established within the layers of the broad ligament. Finally, they might be quite separate from the uterus. A case was recounted of an adenomyoma in the base of the broad ligament still adhering to the uterus, but attached by a very fine, long pedicle. The stage further would have been complete separation, and to explain the presence
of a tumour containing glandular epithelium in such a situation the favourite theory was an origin from hypothetical Müllerian or Wolffian duct remains or a metaplasia of peritoneal inclusions. These hypotheses were rejected in favour of the migratory theory. He instance two cases of adenomyomatous of the recto-vaginal septum that had come under his notice. In one of these the gland tubules had actually penetrated the rectal wall as far as the submucosal layer. In both he could trace the tumour to the cervical portion of the uterus, and in both the cervical endometrium had penetrated far into the musculature, both approaching and, he thought, being continuous with each other. He reported in full a case in which a small tumor formed on the anterior wall of the uterus opposite to a tumour in the sigmoid loop of the pelvic colon. Both were typical adenomyomata, and the sections showed that the separation between the was quite recent. He thought that the original tumour had migrated through the uterine wall, had adhered to the dependent colon, and that the tubules had infiltrated the wall of the latter. Adenomyomatous were infiltrating benign tumours of a migratory character, always associated with a definite condition, in which locality they were finally found they had the markedly typical characters that separated them from all other conditions. He had two cases which had taken on malignant change.

The views expressed on these two papers were adopted by Dr. Cuthbert Locke, followed by Dr. Herbert Spencer, who said he did not think that the cases of retro-uterine and sigmoid adenomyomata shown by the President and Dr. Locke were of endometriosis, but that it was well known that the peritoneum formed decidua during pregnancy, and its presence in the President’s case was no proof of Müllerian origin. He looked forward to the future history of that interesting case. One of the most important is the probable incidence of the peri-rectal fibrosis it set up. Wolff had found X-rays of little benefit in adenomyomata. Dr. Spencer had pointed out a year and a half ago, in discussing Dr. Locke’s case of excision of the uterus and rectum and vagina, that the researches of R. Meyer, Amann and Regisch showed that the growth arose in the peritoneal endometrium. The researches of Pick, Orloff, Ivanoff, Optiz and others, and examination of the speaker’s own three cases confirmed the interest in which he was interested to see Dr. Locke now adopted. Migration of endometrium and the Müllerian and Wolffian theories did not explain some of the remote adenomyomata, which had been observed in the small endometriosis, as in the pedicle of a ventro-tixed uterus. Dr. Spencer had in his last case performed hysterectomy and dissected the growth from the rectum with the gall-valvomacutery. The patient, recovered, with no evidence of a local reaction. He agreed with Dr. Locke that adenomyosis was not a tumour except in the clinical sense. He thought also that the ordinary diffuse uterine “adenomyomatous” was not a “tumour,” but a hypertrophy and hyperplasia.

Dr. Walter Tate and Dr. Williamson also spoke. The President and Dr. Archibald Leitch replied. Dr. W. S. A. Griffith then delivered his Presidential Address, a full report of which will appear in the Medical Press. Votes of thanks were given to the retiring Officers of the Section for 1913-1914.

SPECIAL REPORTS.

ROYAL COMMISSION ON VENEREAL DISEASES.

At the forty-fourth meeting of the Royal Commission, evidence was given by Mr. J. E. R. Macdonagh, one of the Surgeons at the Lock Hospital, and by Dr. Parker, Military Surgeon, Medical Administration. Mr. Macdonagh said that at the present time the education of medical students in regard to venereal disease was quite inadequate, and it was very important in his opinion that compulsory clinical

education of students in venereal disease should be adopted. He considered that widespread clinical experience would render public laboratories for carrying out bacteriological and other methods of diagnosing syphilis superfluous. The important thing in dealing with syphilis was to treat cases at the earliest possible moment, and these early cases could be diagnosed with greater certainty by clinical than by pathological methods. A negative Wassermann reaction in any form did not necessarily refer to a cure; and if treatment were deferred until the reaction became positive, the golden opportunity of cure was lost, however energetic the treatment might be. Syphilitic sores, moreover, frequently escaped in which syphilitic nerves, injected and infiltrating, would be on the increase, and he considered that the spasmocytic administration of salvarsan commonly practised in this country was likely to lead to disastrous results. This spasmocytic pruritus of the drug, moreover, gave a false sense of security, and therefore rendered patients a greater danger to the community. He advocated that the Lock Hospital should be enlarged. The number of patients attending the hospital was steadily increasing.

Dr. Parker maintained that by the establishment of a State medical service many difficulties now connected with the treatment of venereal diseases could be overcome. The essential features of such a service should be efficient and confidential, and in the last resort compulsory, and that the Medical Officers of Health should be in touch with all cases of venereal disease. Efficient treatment would be procurable for the whole State service and would be open to the patient. The treatment of venereal disease would be both a part of the preventive and curative treatment offered to all sufferers alike under a State Medical Service. No action whatever would be taken on the part of any public authority as long as a patient attended regularly and carried out the instructions of his medical attendant; but should he fail to do so he would be proceeded against as a public danger in the same way as is done in the case of ordinary infectious diseases. Dr. Parker considered the difficult question of notification would be under a State Medical Service, or in the sense of a notice sent by a private practitioner to the Medical Officer of Health would become unnecessary for all patients attending a State doctor would be registered with the history and nature of their case, and the Medical Officer of Health, who would represent but another part of the same Service, would have daily access.

At the forty-fifth meeting the headmasters of Eton and Rugby appeared before the Commission. The considered method of the ideal was that boys should be instructed in matters relating to sex by their parents, but their experience showed that that method was not likely at the present moment to be successful to the extent that it is desirable; that the school should be given with much caution, and it should be the special responsibility of the headmaster to give it or to see that it was given. A propaganda based solely on hygienic principles would not find a public appeal which was necessary and was not likely to succeed. At the same time hard exercise, hard work, wholesome society and moderation in diet and drinking were of great use as safeguards against indulgence.

Dr. Bonner Harris Muxby, M.D., C.M., M.R.C.S., of Portsmouth, for 18 years Medical Superintendent of the Portsmouth Lunatic Asylum, and prior to that Medical Officer of Health for the Borough, left estate of the cross value of £13,200.
OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Carcinomatus Stricture of Rectum.—Mr. Berry operated on a woman, aged 41, who had been admitted for constipation and haemorrhage. She had been ill for nearly two years. Nearly a year ago she began to be very constipated. She passed urine and blood, and the patient thought this was due to the formation of the tumour of a healthy child. For a fortnight previous to admission the pain grew worse and she had no normal motion. A ring carcinoma could be felt about two inches from the internal sphincter. At the operation Mr. Berry opened the abdomen, making an incision in the middle line. On examination of the viscera a secondary node of carcinoma as large as a walnut was found in the mesentery. It was, therefore, evidently useless to attempt removal of the rest of the rectum, so a simple colotomy was done. A colotomy was carried out, a Paul's tube being tied in. Mr. Berry said he knew no operation with such a variety of methods of being performed as colotomy. A great point to consider was whether the colotomy was only to be utilised as a temporary exit for the contents of the bowel or if the artificial anus was to be permanent. He pointed out that it was most important for the patient to be washed off before being fixed in position. There are many ways of forming a spur in the operation for cases of temporary colotomy; there is the slipping of a glass rod underneath the loop of intestine through a small hole in the mesentery, resting the ends of the rod on the abdominal wall, the rod is left in position three or four days before the bowel is opened. In cases where a permanent colotomy is desired, one of the best methods is to unite the posterior part of the rectus sheath and leave a small hole in the mesentery, then to tie very stout or thick silk ligatures round the bowel outside the abdomen, leaving a portion of bowel to slough away subsequently; this provides two separate colotomy openings, the upper one permitting fascial matter to escape, the lower permitting irrigation of the lower part of the bowel, should that be necessary. It should be necessary to open the bowel at the time of operation, a Paul's tube can be tied into the upper end of the bowel, whilst a stout silk ligature is left tied round the lower end; generally this separates in the course of a few days, but by this time the peritoneal cavity is well shut off from all risk of infection.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, July 11th, 1914.

Nocturnal Incontinence of Urine.

The treatment of nocturnal incontinence in males consists in practising injections of artificial serum into one of the parts of the bladder as high up as the view of distending the terminal nerve filaments of the region, and so provoking a stimulating effect on the neck of the bladder and the striated muscles of the urethra. The method employed of these injections is simple: the patient being placed on his back and in the position for lithotomy, and the skin disinfected with iodine, the injection is made with a Roux syringe half an inch on either side of the raphé and midway between the scrotum and the anus (a) the needle should not be pushed beyond the cellular tissue and the liquid injected as rapidly as possible, so as to form on each side a tumour containing from two to four ounces of serum; four or five syringes are necessary. The operations almost painless, and do not prevent the patient from resuming immediately his occupations. In general from three to four ounces of liquid on each side are sufficient, but the dose may be increased if required. The author, Dr. Galibert, has utilised this method in twenty cases; the results were excellent in twenty-four patients—eighteen were cured after the first injection, six required two or three sittings, while the remaining six patients experienced no benefit.

Delamare applied the method to two patients and obtained four cures with only one injection, two after two injections, while three required four or five sittings, but all were cured. Bergasse had twenty-two cures out of twenty-two patients treated, and Gray five out of seven cases. The treatment may also be employed in children, but the quantity of serum should not exceed one or two ounces, so as not to distend the teguments beyond measure.

Hydrocele.

The classical medical treatment of hydrocele consists in evacuation of the liquid, injection of two drachms of a solution of cocain (1:50) left in for five minutes and followed by tincture of iodide for the same time. The method is good, but rather painful.

Dr. Sattre prefers, after tapping the liquid, injecting 50 drops of a solution of adrenalin—half a grain of adrenaline for four ounces of water (0.02-100). This method has the advantage of being entirely painless, while relapse is rare.

Supra-renal Virilism.

Prof. Tuffier, present at the meeting of the Académie de Médecine, a woman, aged 62, who entered the hospital six months before for abundant metrorrhagia indicating a voluminous fibroma. As the urine was found to contain a large quantity of sugar, all operation was deterred. While this was the case, it was extraordinary to have an extraordinary development of hair on the face and more or less over the body; the beard and moustache were well furnished, the voice was masculine, while the muscles were well developed and outlined. Examination of the genital organs showed a clitoris an inch long and covered with a large prepuce. All these phenomena began to appear after the menopause, and at the same time the habits of the woman underwent a change; she showed a preference for hard manual labour. Through medical treatment the sugar diminished more or less rapidly, so that at the end of six weeks laparotomy was possible. No fibroma was discovered, but on the other hand the uterus was abnormally hypertrophied and removed. In exploring the abdominal cavity, M. Tuffier came on a lipomatous mass covering each kidney. In his concluding remarks, M. Tuffier thought, with Gilbert Ballot and Galliés, that signs of virilism in the female should attract attention to a possible supra-renal tumour which, recognised at an early date, could be treated with some chance of success.

Varicose Veins.

The usual treatment of varicose veins is the wearing of an elastic stocking or bandage and iodide of potassium or haminamol given internally. However, something more might be done to the satisfaction of the patient. Prof. Robin advises washing the legs each morning with a solution of silicate of soda (1-100), leaving the sandy matter, and powdering them with

- Starch powder, 2 oz.
- Oxide of zinc, 3 dr.
- Camphor, 1 dr.
- Essence of geranium, 6 drops.

Internally, six drops at each meal and continued for months of

- Tincture of haminamol, 1 dr.
- Tincture of viburnum, 1 dr.
- Balm of pleurisy 3 dr.

If scoliosis of the walls of the veins exists, iodide of potassium and bicarbonate of soda must be given and the following ointment passed over the veins:

- Iodide of potassium, 1 dr.
- Vaseline, 1 dr.
- Tincture of nux vomica, 15 drops.
- Axxane, 1 oz.

Raths of Bagnols salt, followed by gentle massage, are also to be recommended, or better still, the patient might be sent to the baths of Bagnols-de-l'Orcet.
At the Gesellschaft der Chirurgen in December last. Three years before she had suffered from symptoms of gastric ulcer. She was admitted into the Charité in December last. Three years before she had suffered from symptoms of gastric ulcer; she had vomited blood and was then free from trouble. In November she began to have repeated vomiting of blood. The patient was admitted, as after two days the haematemesis never ceased, and the patient's death was certain if nothing was done. He was taken to operate, and, bearing in mind the desperate nature of the case, proceeded to do so. He was able to show the patient alive; she was not strong, but she had never been so. (Patient shown.) They saw the oblique incision. It healed per primam; she eaten her food and, as regards the stomach, was quite free from trouble. Under such circumstances the surgeon was placed in a precarious position. Of the four chief complications of gastric ulcer—haemorrhage, perforation, stenosis and malignant degeneration—the last named bore small; the first and second seemed a clear distinction, and would not be likely to do so. The surgeon only came into the question in haemorrhage in rare cases. Here there was first abundant haemorrhage, secondly, this had recurred after only a short interval, and also the patient was much wasted. The haemoglobin content was reduced 30 per cent., the number of erythrocytes was two millions. Much could have been said against active treatment, the bad condition of the patient, who could not stand any operation. For this reason a strictly vital indication could not be operated. Secondly, there was the difficulty of finding the ulcer. Whilst ulcers perforating into the free abdominal cavity were mostly seen on the anterior wall of the stomach, the haemorrhage was mostly behind, above the cardiac end and difficult to find. Bearing in mind the difficulty of the operation, the decision had to be made whether the ulcer was chronic or recent. The deep ulcers which had eaten through the wall of the stomach and entered the vessels of the pancreas were especially difficult to treat; they were easier to find, but arrest of haemorrhage from the operation was not at all easy. The more recent, which closely resembled haemorrhaging oesomorions, were often less difficult to find and easier to repair and normal to surgical treatment. From all that could be learned the ulcer was seated on the pylorus. He made a wide incision in such cases, as small ones were of no use; the whole thing was a question of moments; the body of the stomach was opened slowly, the incision to the left, and the field of operation was before his eyes. On the pylorus was an imperceptible thickening. They opened the pylorus nothing was to be seen of an ulcer. The incision was then closed by suture. His assistants believed the operation would have to be abandoned. He could not resist having another try, so he prolonged the incision towards the cardia, over the stomach until it was only a matter of minutes, with careful wiping nothing could be seen of the ulcer. Then the speaker was reminded of his pathological days, when bodies were sometimes met with in which the stomach was filled with blood clot, but nothing could be found for it until the stomach came out, and showed him the ulcer very small, only a pin's head in size. He passed his gloved hand into the stomach, and between the folds just above the lesser curvature he touched the pin's head. That must be the bleeding spot. A spatula was placed under, and he then saw a clot of blood on the projection. He had a Paquelin with him, and applied it when the clot was washed away and the artery was exposed, thus the ulcer was exposed, and the fresh blood he then applied the cautery and closed up the stomach. Recovery was quite uneventful. Naturally it would be a long time before the normal condition of her blood would be restored. It was only very rarely that haemorrhages from the stomach could be treated in that way. The cases in which such treatment was demanded seldom were fortunate enough for that reason that the ulcer could not be found. The lucky result gave him the opportunity of exhibiting the case, otherwise it would only have been seen on the post-mortem table. He would likewise remark that the cases of the Charité were not composed of selected cases. He had that day made a search through their preparations, but he had not been able to find a similar case in their pathological museum.

AUSTRIA.

TENTH CONGRESS OF THE DEUTSCHER RÖNTGEN-GESELLSCHAFT.—(Continued.)

II.—DIAGNOSTIC APPLICATION (TORAX, ABDOMEN).

Dr. Alban Köhler (Wiesbaden) read a paper on "The Röntgen-ray Diagnosis of the Parasites of Man." He illustrated his subject by photographs of calcified cysticerci in various parts of the body. The calculated rays varying in length from 7 to 9 millimeters, and from 2 to 4 millimeters in width, had been obtained and were now reproduced. These had been met with in the legs, thigh and lumbar region, and the longitudinal axis was that of the parasites. The calcified scolices in which it happened to be imbedded. Röntgenographs of a lung were also shown by Dr. Köhler, in which calcified ova of the distomum pulmonale were freely disseminated throughout. The shadows were circular, often variable in outline, from about 2 to 5 millimeters, in diameter. The diagnosis was also confirmed clinically by examination of the evacuations. A specimen was also presented the round shadows of which had at first been taken for that of an echinococcus, which had proved to be that of metastatic carcinoma.

Dr. Hessel (Bad Kreuznach) made a communication on "A method by which the normal Oesophagus could be illustrated with the help of the stomach. The piece of pith or the capsule which had been filled with a contrast test meal was swallowed, and by its presence he was able to demonstrate the process of swallowing, after which he observed its passage during its passage through the body. In the course of the subsequent discussion, Dr. Holzgeheben (Vienna) stated that the outlines of the oesophagus could be demonstrated during the passage of a mouthful of ordinary solid food. He had observed that more ascending movements were made during the first part of the act of deglutition, some of these being functionally effective.

Dr. Grünemann (Berlin) discussed the subject of the "Diagnosis and Therapeutic Treatment of Gastric Spasmus," and exhibited a number of examples, adopted as a contrast test meal and the effect of the stomach. With regard to this point, Dr. Haudek (Vienna) remarked that we should be cautious in making a diagnosis of gastric spasmus. Dr. Schwarz (Vienna) then stated that in making a diagnosis of gastropusmus there were three varieties, characteristic of this condition which require to be differentiated: the first is that which accompanies the presence of ulcers; it is characterised by retraction of the great curve of the viscous. The second is the spasm occurring in the cardiac part of the stomach, and the third is the spasm occurring in the pyloric end of the stomach. In the first variety the muscular force is greater, and the second variety is characterised by the fact that in the pyloric portion of the stomach it is the pyloric end which is constricted. In the third variety there is a muscular spasm of the pylorus; and the contraction recurs periodically. When the test meal is introduced into the right side of the pyloric end of the stomach the pyloric end is constricted, and the pyloric end of the stomach is constricted. The third type of spasm is the muscular spasm of the pylorus, which may be constricted or in a state of marked constriction.
The sedimentary deposit after the test meal, which he had himself observed, and its presence in the duodenum after flushing would form items of evidence. The clinical part of the case, the causation of retention, appeared to Dr. Hauck to be a resultant of two factors—a high degree of hypersecretion and high elevation of the viscus. In a case of long, hooked stomach, the retained residue of the test meal very soon took place in the presence of hypersecretion, and a marked retention of the diurnal meal sank to the bottom of the gastric cavity, while, in the upper parts of the same, as well as in the antrum pylori, a bismuth-free fluid collected. The presence of the stomach and a new collection formed, the visible amount of gastric contents being thus but little diminished, while a gradually diminishing sedimentary deposit remained for a number of hours. Thus a high-grade bismuth retention in a sharply-curved stomach is an excellent evidence of high-grade hypersecretion; and as this is in turn elicited by the presence of gastric tumours the presence of a gastric sediment is indirectly symptomatic of the presence of a neoplastic growth in that cavity. In the case of a duodenal tumour, on the other hand, hypersecretion also exists; but the hypertonic condition of the muscular wall of the stomach which is produced by its presence, and the fact that such growths usually occur in persons with slanting stomachs have the combined effect of bringing down considerably a deposit of a case of ulcus duodeni after the lapse of six hours—except a very slight one in the vicinity of the caudal pole of the cavity of the stomach. In the case of a long, hooked stomach, however, it may be found to remain in moderate quantity, an interval, even when the initial evacuation had begun early and proceeded quickly. The author had confirmed these observations by experimental researches with canine and human subjects.

Dr. Hainsch asked whether in such cases—with hypersecretion—the peristalsis was diminished, while it was increased in the presence of pylorospasms.

This fact by itself forms a diagnostic landmark. Dr. Grodberg had observed that in the absence of a persistence of the duodenum co-exists with a Holzknecht stomach, it is indicative of functional insufficiency, while in the case of a hooked stomach the chyme is held back.

Dr. Hauck, in reply, stated that in a distended stomach deep peristaltic waves were typical of pylorostenosis. But they first appear after a considerable interval.

Dr. G. Schwarz (Vienna) made communications which discussed the use of acid test capsules. Gelatine capsules were filled with test powder and tied with thread dyed with Congo-red. They were then swallowed, while the free ends of the threads were held in the mouth. The presence of the capsules was indicated by a red staining observed by Rontgen-ray illumination; they were withdrawn after ten minutes, when the capsule was seen to be dissolved. The colour reaction then gave the proportional acidity.

Dr. Lehmann (Rostock) demonstrated a "sopor" hair mass in the stomach of a girl, aged 15. The foreign body was seen to form a complete cast of the stomach, the Röntgen picture of which showed a spotty outline, which moved with the stomach. The mass on removal was found to weigh 496 grammes.

Dr. Hauck then demonstrated a similar case.

Dr. Ley-Dorn and Ziegler made a communication, "On the Characteristic of Röntgen-ray Gastric Symptoms as revealed in numerous Autopsies." They had tabulated the results of 46 cases in which the clinical and Röntgen-ray examination had been controlled by operation or post-mortem dissection—sometimes by both. The revelations of surgical procedure could not be regarded as final, and a plea was made for a comparison with those of post-mortem examination in no less than five instances. Further observation had led them to raise the question: how far the revelation afforded by a graphic-ray picture could be relied on as a demonstrative of the condition of the stomach. Scarcely a single sign or symptom was conclusive, so that repeated observation should be carried out and controlled by clinical evidence. Among other sources of confusion was the presence of gastric adhesions—a very important one. The same could be said of gastric tumours. The outline of the sedimentary deposit is often segmented by the presence of tumours. Adhesions may draw the stomach in various directions; those of the pylorus may have displaced it as much as 4 centimetres to the right. The stomach, when adherent to the gall-bladder, can give positive only in the presence of ptosis and a high-placed and transverse pyloric end.

Dr. P. H. Gracdel (Budapest) made a communication on the "Evidence given by the Röntgen-rays in Cases of Ulcus Ventriculi and Ulcus Duodeni." Of the presence of these lesions he presented two examples, in which the evidence had been confirmed by a direct observation of each lesion. They were insufficient, and it was by the radiological evidence obtained before the operation that the multiplicity and unusual position of the lesions had been ascertained.

Dr. Hauck (Vienna) stated during the discussion that hundreds of microscopic ulcers had been demonstrated by the Röntgen-rays which could not be found by the surgeon. He also referred to the sources of failure which were referable to periduodenitis and to alterations of pancreatic function.

Dr. F. M. Graedel demonstrated the presence of tuberculous tumours in the ileo-cecal region with the Röntgen-rays. He also showed how insufficient the evidence of Bauhin's valve by itself of this lesion.

Dr. F. M. Graedel demonstrated the presence of abnormal foldings of the duodenum and of the jejunum. He had also succeeded in influencing the course of the contents of the last coil of the small intestine, and depressing the tone of Bauhin's valve by those of the ileum.

Dr. F. M. Graedel demonstrated the presence of chronic appendicitis with ileo-cecal invagination.

Dr. Hainsch (Hamburg) and Dr. Schwarz (Vienna) made communications on the Röntgen-ray diagnosis of lesions of the large intestine. The former demonstrated a shadow of carcinoma of the sigmoid flexure, and in another in the ileo-cecal region, pronounced stenosis of ascending colon, peristomalitis, syphilitic lesions, ulcerative colitis with hepatico-ptosis, Hirschprung's disease, megacolon, and the invagination of the cecum which had passed into the descending colon, in a baby of seven months. The latter also demonstrated a number of tumours, syphilitic alterations, and polypi of the large intestine.

Dr. Dr. Ziegler made a communication on "The Diagnosis of Commencing Dilatation of the Aorta, especially of the Arch and Descending Portion."

UNITED STATES OF AMERICA.

New York June 30th, 1914.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

The sixty-fifth meeting of this Association, which began in Atlantic City on June 22nd and lasted up to June 27th, was the largest in the history of the Association. The work was opened on June 22nd.

The opening session held in the Apollo Theatre on the Broad Walk.

Dr. Witherspoon, the retiring president, as a last official duty, presented, on behalf of the Association, a gold medal to Dr. Willing. The former president, whose genius made possible the construction of the Panama Canal.

The President-elect (Dr. Victor C. Vaughan) was introduced, and delivered his presidential address. He took as his subject, "The Service of Medicine to Civilisation.

and said in part that the history of medicine was that of mankind. Born in naked ignorance, bound in the swaddling clothes of credulity, and nursed on superstition, medicine has had its savants and its takers, its triumphs and its failures, its honours and
an alkaline solution every five minutes after the injection until a pink colour is observed, and every hour afterwards until the colour is no longer present. Several bottles are numbered for the reception of the specimens in the order passed, and their contents must be made alkaline if not already so. In no case should the dye appear in the urine in from five to ten minutes, and its excretion should be completed about the end of the third hour. The fourth bottle of urine would therefore be uncoloured, those preceding it showing the different stages in which the appearance of the dye in the urine is delayed and the time of elimination prolonged, the result will be apparent in the bottles accordingly. Cases of valvular disease and of toxemia of pregnancy having indicated the necessity of casual cases, were discharged from five to eight hours for complete elimination, and a cardio-renal case which died four weeks later had appearance delayed more than fifteen minutes, and excretion required sixteen hours.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Panel Doctors' Incomes in Glasgow.

It appears from the minutes of Glasgow Insurance Committee that at January 11th last 374 medical men were on the panel. This represents about three-fourths of the profession in Glasgow. For the year that ended on the above date one doctor received 3,162 8s. id. for having 4,468 persons on his list, and another received £1,453 8s. 8d. for 3,983 persons. Four with an average of 3,275 patients received an average £1,188 8s. id. each, and seven with an average of 1,895 patients an average £66 15s. 8d. each. Again, 17 with an average of 2,223 received on an average £57 17s. 6d., while 46 for an average of 1,715 persons received an average £61 18s. 2d. Further, 65 for an average of 1,236, received an average payment of £47 13s. 6d. for an average of 725 received an average payment of £26 2s. 6d.; and lastly 158 doctors for an average list of 101 persons received an average payment of £6 12s. 4d. During the same year, £1,097 was paid to 10 practitioners whose names were withdrawn from the panel list owing to resignation or death. The total of payments to chemists, etc., was £2,522 10s. 11d., while £1,177 10s. 10d. was paid in respect of insured persons permitted to make their own arrangements for medical attendance at the special expense.

The Royal Visit to Glasgow.

The King and Queen opened the reconstructed Royal Infirmary and the new Royal Hospital for Sick Children on 7th inst. At the Royal Infirmary, their Majesties saw an electro-cardiograph taken of the pulsations of a patient's heart, under the superintendence of Dr. Macintyre, consulting medical electrician to the hospital. In the cinematograph X-ray room the King and Queen saw X-ray photographs being taken in the three-hundredth part of a second, and also a series of photographs taken pictorially in rapid succession. Shortly afterwards by means of an apparatus which fills the photographs were shown on the screen. The next apparatus inspected by their Majesties enabled them to see, clearly defined, the movements of the stomach in digestion, and also the operation of the electrician. The latest appliances for directly examining the throat and windpipe also aroused much interest, the apparatus being attached to an imitation bullet into which a coin had been inserted. The method of extracting it was later shown to the officials entrusted to their Majesties, who next saw the means by which tumours in the throat and lower down in the respiratory track can be removed by the deep-seated X-ray therapy without morbidity in cases unsuitable for operation. The first photograph of the new ward was made at the latest arrangements for testing the muscles and nerves, and afterwards an apparatus for the removal of superfuous fat from the body. The patient rests
on a couch and electrodes are placed on any part of the body where it is desired to remove deleterious products. By a simple arrangement faradic currents are sent to any part and the muscles are made to contract. Weights made of sandbags are put on the body, up to 10 lb., and upon them are made a few times more than the number of the beats of the heart per minute. It is possible, when a person with a weak heart cannot take exercise, to remove as much as 1 lb., or more per day without any exertion whatever on the part of the patient.

At the Sick Children's Hospital.

His Majesty was especially interested in the excellently equipped theatre, which is lighted on the search-light principle, and listened to a description of it by Dr. T. Kennedy Dalziel, senior consulting surgeon of the hospital. After the operation performed by George S. Middleton, senior consulting physician, was also presented to their Majesties. After leaving the hospital the King and Queen visited the grounds of the Western Infirmary and of the University, and received an address from each. Lord and Lady Newlands have made a donation of £25,000 to the Western Infirmary, the endowment of the Lady Hozier Convalescent Home at Lanark and to commemorate their Majesties' visit to Glasgow and Lanarkshire.

BELFAST.

Belfast Local Medical Committee.

A meeting of this committee was held in Belfast on the 7th inst. by J. Johnston, president, presiding. The following papers were sent forward to the Insurance Commissioners at their request as being suitable for election as members of the Belfast Insurance Committee:—Dr. J. R. Davidson and Dr. T. A. Davidson. The latter has acted as Secretary of the Local Medical Committee since its formation with much acceptance to the members and the profession generally, and the former seeks re-election. If the Insurance Commissioners are satisfied by this selection, the profession in Belfast will be perfectly satisfied.

Queen's University of Belfast.

There was a large number of candidates for the degrees in medicine at the midsummer examinations, no fewer than 46 presenting themselves for the M.B. degree examinations. Of these 37 were successful, 14 being referred. The honours list was the largest in the history of the University. One candidate, Mr. R. M. Beath, obtained first-class honours with a scholarship of £30. Mr. G. R. B. Purie and Mr. W. S. B. Hay obtained second-class honours and scholarships of £50 each. Mr. Sinclair Miller obtained second-class honours with a scholarship of £20, and Messrs. A. Fullerton, E. B. C. Mayes and E. C. T. Young obtained second-class honours. At the M.D. degree examination Mr. D. McKay obtained a gold medal. The Magrath Scholarship of £105 was won by Mr. Sinclair Miller. At the M.Ch. examination Mr. T. S. S. Holmes obtained a gold medal.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

IMPERIAL ASPECTS OF THE POPULATION QUESTION: THE DECAY OF FRANCE.

To the Editor of The Medical Press and Circular.

Sir,—The much more than remarkable correspondence dealing under different headings with the question suggested in the title of this letter is still going on in the Times. The correspondents are men of real distinction. It is curious that not one of them alludes even distantly to the population phenomena displayed in France; not one of them refers to France as a voluntary birth-rate. In the birth-rate in France has made her population stationary when compared with her mighty neighbour Germany: that she has not enough men for her home requirements; that she has for ever lost her place as co-equal among the Great Powers; and by cutting off the supply derived from abroad a people has made it impossible that she can ever become a great imperial state. She has no surplus to export to her vast territories across the sea well fitted for European settlers. There are, for example, practically no Frenchmen in the West African colonies. The Niger, long, is traversed by a chain of mountains whose slopes accommodate one of the finest climates in the world, whilst the lower lying lands, thanks to medical science, could in great part be freed from tropical disease. It is a publishing fact that experience is beginning to hold that art and literature, in the field of intellect, but she lacks mea. She is enormously wealthy. She recently brought out a loan of £40,000,000, which was at once offered for forty times over almost entirely by her own people. It is a people among whom wealth accumulates and men decay, and it is absurd to suggest that amidst this wealth it can be in any large proportion of cases economic pressure which leads to the limitation of the family to two or three children.

B. Tt. Prof. S. J. Furum.

The modern fashion in medicine is to seek in the colon for the explanation of the majority of diseases to which our flesh is heir. Since Elie Metchnikoff some seven years ago published his fascinating book of optimistic studies on the Prolongation of Life, one can trace the rapid rise of this organ to a place of importance as a causative agent in pathological conditions. The medical church is quite content and would appear that some would advocate that every sick person, and many apparently healthy ones, should submit to be deprived of their colons at the

REVIEWS OF BOOKS.

The Medical Press. 77.

earliest opportunity. Some, on the other hand, recommend that the colon should be preserved, and in its rich content of flora and fauna should be sought not only for its therapeutic agents for administration to the patient. The latter idea is no new one, for though nowadays only selected parts of the fecal content are used as medicines, yet formerly the entire mass was frequently recommended. The authors of the book before us have not adopted either of these extreme views, but have contented themselves with describing with minute detail one form of disease of the colon, and in giving most elaborate directions for its treatment. It is not proved that the disease has a real existence we have no doubt, and that when present its recognition and cure will be of great benefit to the patient is also certain, but we doubt very much if it was necessary to devote a book of 370 pages to this work. However, our authors believe that their book is the first English manual that has appeared on the subject, and we may be permitted to hope that it will be some time before its pre-eminence is disputed.

STEWLAW ON SKIN DISEASES. (a)

The appearance of a seventh edition of a standard American treatise on diseases of the skin is a matter of interest to all concerned in that special branch of medicine. It contains some 1,100 pages in octavo of 330 illustrations, many of the latter possessing considerable technical excellence. In common with many American reference books, it shows a striking breadth of comprehensiveness as regards comparatively rare and out of the ordinary cases, that account lessen the grip of individual experience, which is, of all things, important to the serious student of a special subject. It is impossible to do justice to a book of this quality within the limits of a short review, but a few random notes may be made. Turning to "warts," we find a full discussion of this interesting condition. The credit of observing micro-organisms in connection with these growths is ascribed to Kühne, though the growths as a matter of fact, his work was, we believe, based on that of Majorchi, who described the bacterium pox in connection with warts. The article on syphilis is able and interesting, and is illuminated by some illustrations of striking clearness. There is a beautiful coloured plate of an acroform pustular syphilomad of general distribution. In dealing with drug rash the theory of irritation in the process of elimination is mentioned; but in spite of abundant bibliographical references the possibility of this theory is not made of the English author by whom this suggestion was originally advanced. The book may be recommended as an excellent work for all dermatologists.

SCROFULOSIS. (b)

Progress in medicine has not infrequently been checked by the tyranny of a name, which, though apparently definite and precise, is merely a mask of ignorance. Groups of symptoms, or disease pictures, in perfectly undefined, and the more copious the description, and when that name has become sufficiently familiar there is a tendency to consider the picture explained as soon as it can be classed under its official nomenclature. In olden days the term scrofula was used to describe the condition of certain persons with swollen necks from their supposed resemblance to a pig. Such swollen neck was often found to be due to enlargement of the lymph glands. Where the condition was due to the enlargement of lymph glands the term is used, but the distinction was soon lost, and stramous and scrofulous came to be used almost as synonyms, and extended vaguely to that condition of the patient which so frequently accompanies certain forms of lymphatic disease. Out of this arose the use of the term scrofula, but it is not made that many forms of glandular enlargement were due to infection by the tubercle bacillus it seemed as if some definiteness was to be introduced into the meaning of the term scrofula, and for some time, in these countries at least, the term became synonymous with tuberculosis. More recently an effort has been made to differentiate between the two terms and to restrict the meaning of scrofula to include those conditions of young people which form a suitable breach for the tubercle bacillus, but which have not yet been infected by it. That there is such a condition of children is probable, but whether it is wise to designate that condition as scrofulous we doubt very much if it is. When such a disease should disappear altogether from medical nomenclature. While we differ from Professor Corree in his use of the term, we are in full agreement with him in the importance of the conditions which he describes, and we are indebted to him for the admirable description of them which he gives. Not only are these conditions well described, but the treatment, both from the point of view of prevention and cure, is given in a wealth of detail which makes a valuable and interesting contribution to medicine. A full biography is a notable addition to the work and greatly increases its usefulness.

MEDICINAL TREATMENT. (c)

It is not necessary to do more than draw attention to the second edition of the English translation of Professor Oertel's work, which is already in its fifth edition in the original German. The translation is primarily intended for the use of American practitioners, and the references to climatology have been adapted for their use. This, however, does not make it any way detract from the usefulness of the book for students in Great Britain, as both English and Continental watering places are mentioned. The translation appears to be well and carefully done, and Dr. Bartlett has succeeded in giving us the author's meaning in idiomatic English.

MINOR MEDICINE. (d)

Since Dr. Wynter's little book was first published in 1907 it has been reprinted four times and now a second edition is called for. We congratulate the author on the success which such a history indicates, and feel sure that a similar warm reception will be extended to this second edition as was given to the first. Minor ailments are just those conditions which the young practitioner is first called upon to treat. When his patients are taken ill in the hospitals has given him little or no help in knowing what treatment to employ. It is a mortifying position to find oneself in, yet we fancy it is not uncommon. It is no easy matter to supply this want efficiently, but our author appears to have succeeded admirably. Trivial symptoms often indicate serious disease, and one must guard against the danger of mistaking the beginning of a serious illness for a minor ailment. If, however, we use the book for the function it must treat of minor ailments, and not become a complete system of medicine. Dr. Wynter appears to have admirably avoided the pitfalls that beset his path and to have given us a book which is fully as practicable and useful.

The appendix of "Formulae" at the end will be found of great use by many.

(a) "Treatise of Diseases of the Skin." By Henry W. Stewlawn, M.D., Professor of Dermatology, Jefferson Medical College, etc. Philadelphia: J. B. Lippincott Co. 1914. 8vo. pp. xvii. and 516. Price 1.50.

LITERARY NOTES.

MESSRS. BAILLIRE, TIMDALE AND COX announce the following new books and new editions—

"Intensive Treatment of Syphilis and Locomotor Ataxia by Aachen Methods." (Price 3s. 6d.) In this look the author, Dr. Reginald H. Hayes, maintains that inunction methods are still the best in many forms of syphilitic infection.

Dr. Langdon Brown's "Physiological Principles in Treatment" (price 3s.), has rapidly reached a third edition. From the first this has been a successful book and in the revised edition much new material has been added, dealing with the latest methods of treatment.

The eighth edition of the late Dr. Murrell's "Aids to Forensic Medicine" (price 2s. 6d.), makes its appearance after revision by Dr. W. G. Atchison Robertson, of Edinburgh. Additions to meet present day requirements have been made and some of the material has been rearranged with the object of rendering the various sections more consecutive than they were. "Insanity in Everyday Practice," by Dr. E. G. Younger, third edition (price 3s. 6d.), is another little book which has met with ready acceptance. The previous edition has even been translated into Chinese, and is being translated into Spanish. A thorough revision has been made throughout, and the section on General Paralysis has been entirely rewritten.

MEDICAL NEWS & PASS LISTS.

Memorial to the Late Dr. Wilson.

A statue in honour of Dr. Edward Adrian Wilson, one of Captain Scott's companions at the South Pole, was last week unveiled in the Cheltenham Promenade by Sir Clements Markham. Dr. Wilson was educated at Cheltenham College. The statue, in bronze, which is the work of Lady Scott, and rests on a pedestal of Portland stone, depicts Dr. Wilson in Antarctic sleighing kit. The pedestal bears the following inscription:—He died as he lived, a brave and a true man, the best of comrades and staunchest of friends.

Damages Claimed against a Dentist.

In Bloomsbury County Court, last week, a claim for damages for disfigurement of her face was brought against Dr. MC. Peyton Balny, of Harley Street, Dental Surgeon at the Great Northern Hospital, Holloway Road, by Ethel Brown, a domestic servant, of Lordship Park.

The girl said that on recovering from the gas, after having four teeth extracted at the Hospital, she felt "pins and needles" in her neck. She was about to put her hand to her face when the defendant stopped her, and said, "Good gracious, I have burned this woman." He admitted that some corrosive acid had been used, and the girl now had a disfigurement which plaintiff's counsel, Mr. R. L. Willis, stated would be permanent.

Dr. Baly said that the girl was in a state of collapse, and while watching her he put his hand up to a bottle-cupboard for the smelling salts. After applying the bottle to the girl he found there was some fluid in it. He afterwards found it was the wrong bottle and used in the skin department—should not to have been in this cupboard. The bottle was the same size and colour as the smelling salts.

Medical evidence was given that with proper treatment the scar would probably be considerably improved.

Judge Bray said that in his opinion the doctor was negligent in not looking at the bottle. He gave judgment for the plaintiff, and postponed for three months the assessment of damages so as to ascertain the effect of further treatment.

A Faith-Healer Censured.

The adjourned request on the habeas of Miss Kate Addison Scott, aged 17, was concluded last week at Henchman by Mr. Reginald Kemp. Miss Scott died after staying four days at the Miller Institute, Islington, off Mr. Orlando Miller, who described himself as a lecturer and teacher on Biblical and religious subjects, and a healer and student of psychotherapy. He said he had no medical qualifications, but had studied medicine in America. He healed by mental, chemical and mechanical means, and sought prayer as well. He had no medical man at his home. Miss Scott attended his lectures, and having suffered for 14 years from paralysis, she asked him to help her to get well. He agreed, and she paid him 5s. a week, to which fee was added 15s. in her diet for 36 hours, give her doses of salts and injections of cascara, alcohol, and scopolamine. She vomited considerably, and died before her own private medical man could reach her.

Dr. R. Wilson, of Gordon Square, said he had attended Miss Scott for some time for dyspepsia. Her condition was such that scopolamine would be a dangerous drug to use. He considered that a medical man should have been called in earlier, and then her life would probably have been saved.

Dr. Christian, who made a post-mortem examination, said that he found on the legs marks of the use of the needle of a syringe. Scopolamine would increase the distention of the stomach. In answer to the jury the witness said that scopolamine might assist in causing death by acting on the heart.

Dr. W. H. Willcox, analyst to the Home Office, said he made a careful test for poison in the stomach, and found no, trace of a hallucinoid. It would have the same action as scopolamine or hyoscine, but he could not say if it was either.

The Coroner: What conclusion can you come to? The medical man could not say that it was a case in which scopolamine caused or accelerated death. There was not a poisonous dose in the body. The treatment was most unsuitable. The jury returned a verdict of "Death from natural causes," and asked the Coroner to censure Mr. Miller, and, with regard to the nurse, the expression that her conduct be reported to the hospital which granted her diploma.

The Coroner said he quite agreed with the rider. Addressing Mr. Miller, he said:—"You are deserving of the graver censure for treating this woman in a very improper way. Fortunately the medical evidence is in your favour, or you might have found yourself in difficulties. It was clearly your duty to send for a medical man, and not do what he did on his own opinion, rather than you did. The only extraordinary part of this case is the evidence which affords the easy way in which the public are taken in by these quasi-religious faith healers.

The Royal College of Surgeons of England.

At a quarterly meeting of the Council of the Royal College of Surgeons of England, held last week, Sir W. Watson Cheyne, Bart., C.B., was elected President, and Sir Frederic Eve and Sir Anthony Bowley Vice-Presidents of the College.

Miss Refna Mallett, Royal Free Hospital, and Mr. J. R. M. Collie, University College Hospital, were admitted members of the College. The following Hunterian Professors: Professor Arthur Keith, Messrs. Rupert Farrant, W. Sampson Handley, J. Howell Evans, Frederick C. Pyms (Newcastle-on-Tyne), and Harry Bowley. Battersea: Messrs. F. W. J. Odes and David Waterston. Erasmus Wilson Lecturer: Mr. S. G. Shattock. Artomt Demonstrator: Professor Keith. Odontological Demonstrator: Mr. J. F. Coyle.

University of Oxford.

In a Congregation held on July 11th, the following degrees were conferred:

Belfal University.

The following degrees were conferred on the 6th July:

M.D. Degree (by Thesis).—David Finnegan, Philip
NOTICES TO CORRESPONDENTS. THE MEDICAL PRESS.  79

J. Gaffin, David Mc' Cay (gold medal), Samuel Mc'Clure, William S. J. Shaw, John M. G. Williams. M.D. Degree (by Examination).—Bruce Alexander West.

M.Ch. Degree (by Thesis).—Frederick Crooks. M.Ch. Degree (by Examination).—Thomas S. S. Holmes (gold medal).

Examination Result: Faculty of Medicine:—

Practical Chemistry.—Margaret M. Merrick, W. J. Lytle, F. C. S. Bradbury, Amy C. McCallum, K. Marsh, Elizabeth E. Young, R. W. Hanna.

Senior Anatomy.—J. Lascelles, Annie E. Beattie, C. J. A. Woodside.

Practical Anatomy (Senior).—W. Napier, F. Ewart, C. J. A. Woodside, Annie E. Beattie, J. C. Longridge.

Practical Physiology (Seniors).—A. J. Miller (special prize).

Practical Anatomy (Junior).—G. D. F. McFadden, T. G. Campbell, Amy C. McCallum, T. Montgomery, A. E. Keown.

Materia Medica.—Grace English, J. C. Millan, F. H. Waterfield, Margaret Purse, A. C. Dickey.

Organic Chemistry (Practical).—Kenneth D. Mullen.

Histology.—Dorothy I. Dobbin, R. G. Meyer.

Ophthalmology.—R. L. Rea, G. B. S. Calvert, Mary A. Gallagher.

Pathology.—Elizabeth C. Kirker, William Blyars.

Grace M. English.

Hygiene.—Grace M. English, D. Mitchell, W. Blyars.

Faculties of Science and Medicine:—

Chemistry.—First year, F. W. J. Mc'Clure, William S. B. Hay.

Mathematical Physics.—Third year, Janet S. Nicholls; second year, J. P. Martin; first year, James Martin.

Faculty of Medicine Examination.—

Frederick C. S. Bradbury, Frederick Campbell, William Hoey, Albert Y. Morrison.

Third Medical Examination.—Recommended for Scholarships.—Margaret Sloan Purce, Frederick Hamilton Whyte, William Bryars, (Third Scholarship), James Clark, C. M. Millan (Fourth Scholarship).

Final Medical Examination.—R. M. Beath, £30; G. R. B. Purce, £30; W. S. B. Hay, £30; Sinclair Miller, £20.

Magdazh Scholarship.—Sinclair Miller.

Gold Medals.—M. Ch., T. S. S. Holmes, M. D., David Mc' Cay.

University of Aberdeen.

At the annual graduation ceremony last week, the following Degrees in Medicine and Surgery, and the Diploma in Public Health were granted:

Degree of Doctor of Medicine (M.D.).—Alexander G. Anderson, M.A., M.B., Ch.B., Aberdeen***; William J. Reid, M.A., B.B., F.R.C.S., Royal Faculty, Manchester***; James R. Murray, M.B., Ch.B., 437 Great Western Road, Aberdeen***; Alexander Wilson, M.B., Ch.B.; Douglas Craig, M.B., Ch.B.; William B. Keith, M.B.; Andrew R. Sinclair, M.B., B.Ch., 21 Great King's Road; Francis W. Stuart, Ch.B., Ch.M.

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.), with Second Class Honours.—Neil Cantlie, "George R. Lipp.

The Straths Settlements Gold Medal (for best Thesis for M.D., on a subject dealing with Tropical Medicine submitted 1012, 1013 or 1014) was awarded to Alexander Frank Wallace, M.D. (1913).

The John Murray Medal and Scholarship awarded to the most Distinguished Graduate (M.B. of 1914) was awarded to Alexander Eluslie Campbell, M.A., M.B., Ch.B., Inverness.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of the "Ice Letter" or "Old Subscriber," to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. To avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.
Dawson and Sons are our special agents for Canada. For South African and Colonial Mun- mings, Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

For One Insertion—Whole Page, £1; Half Page, 82s. 6d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following insertions are at Half Price—Whole Page, 12 insertions at £1 10s.; 25 at £3; 32 insertions at £1, and progressive rates for smaller spaces.

Small announcements of Practice, Assurances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per line, or less.

Contributions are freely invited to send their communications, if resident in England or the Colonies, to the Editor, The London Mail, A. Hurrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in retarding from office to office. When sending sub- scriptions for the Journal, or articles to us for publication, it need not be authenticated with the name and address of the writer, not necessary for publication, but as evidence of identity.

Retains—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Dr. J. A. (Battersea) is thanked for his note; the delay will cause no inconvenience.

A MISPRINT.

A CORRESPONDENT has called attention to a misprint on page 30 of our last issue in the paragraph headed "Germ Carriers." The paragraph in question reads: "The germ of diphtheria is found on the faces of persons with the disease; the germ of the correspondent points out that the word "faces" should obviously have been written "face," and added: "The germ of the disease is a small, split-ended, purplish object, and is not authenticated with the name and address of the writer, not necessary for publication, but as evidence of identity."

The printer's error indicated in this instance presents a more than usually complicated tangle.

H. A. FELLOWS (Liverpool)—The drug referred to has no special characteristic feature over similar preparations. It is merely a cut way of advertising it in the newspapers as if it were an Editorial pronouncement.

Dr. J. B. MEYRIN (London) informs us that the title of his paper to be read at the forthcoming Congress of Nephrologists of the British Medical Association is "Urethral Transplantation: Its Limitations and Techniques," not "Archlrologists' readings," as given in a recent issue of this journal.

MEDICAL MEN AND LIGHT CARS.

A large number of medical men are under the impression that only a large and high-powered motor-car is any practical good for their daily rounds. In a special "Doctors' Issue" of the Light Car actual experiences are given of many medical practitioners of the working of small and light cars, from a period of which it will be seen that it is by no means necessary to invest in a 30 h.p. limousine in order to enjoy to the full the pleasures and profits of motoring. We can recommend this special Light Car issue to everyone.

Dr. W. S. T. (London, S.W.)—Such notices in the Iris Press, which are becoming increasingly common, are so to be deprecated, but it is hard to shake the address of the medical men is not given. The attention of the Ethical Committee of the British Medical Journal is well called for, for it is not easy to see the authoritative writing on the points on the subject to be urgently called for. P. R. (Hastings)—We do not think there is sufficient evidence in the case of the man referred to to warrant a charge of culpable negligence. So long as a medical man can show that he has honestly done the best for his patient he can hardly be convicted of culpable negligence.

Vacancies.

Holme Dispensary, Dale Street, Stockport Road, Manchester.—House Surgeon. Salary £120 per annum, with apartments, attendance, coal, and gas. Applications to Honorary Medical Secretary, Holme Dispensary.

Royal Albert Hospital, Devonport.—House Surgeon. Salary £15 per year. Applications to Honorary Medical Secretary, Royal Albert Hospital, Devonport.

Kee Hospital, Asylum, Midstow.—Fourth Assistant Medical Officer, Salary £250 per annum, with furnished quarters, laundry, attendance, coal, gas, and washing. Applications to the Medical Superintendent, Asylum, Midstow.

West Middlesex General Hospital, Harrow.—Resident Medical Officer, Salary £120 per annum, with board, lodging, and his wife at the Hospital. Applications to the Chairman of the Selection Committee, Royal Albert Hospital, Devonport.

City Fever Hospital, Little Bournmouth, Branshfield.—Male Assistant Medical Officer, Salary £250 per annum, with board, lodging, and his wife at the Hospital. Applications to Honorary Medical Superintendent, Bournemouth.

Birmingham General Dispensary.—Resident Medical Officer, Salary £250 per annum, with furnished apartments, free heat, and attendance. Applications to Ernest W. Forrest, 40 West Street, West Hartlepool.

Hospital, Crompton.—House Surgeon, Salary £200 per annum, with board and rooms. Applications to J. C. Tiley, Secretary.

Lancashire and Cheshire Dispensary, Burslem.—Assistant Medical Officer, Salary £125 per annum, with board, lodging, and his wife at the Dispensary. Applications to the Medical Superintendent, Burslem.

HULME DISPENSARY, Dale Street, Stretford Road, Manchester.

WANTED a HOUSE SURGEON duly registered and fully qualified, Salary £150 per annum. Annual increase £10 to £200. Applications to J. C. Tiley, Secretary.

WANTED a HOUSE SURGEON duly registered and fully qualified, Salary £150 per annum, with board, resident, and laundry. Applications to Mr. Jones, Secretary, St. Vincent's Hospital, near Pimlico, London, S.W.

CERTIFYING FACTORY SURGEONS.—The Chief Inspector of Factories announces the vacancies for the following Certifying Factory Surgeons:—Malton (York), Romans (Chester), Shrewsbury (Derby).

Appointments.

BLOUNDON, A. J., M.D., F.P.C.P., Lond., Physician to Guy's Hospital.

DOWELL, J. C., M.D., F.R.C.S., L.R.C.P., Lond., Surgeon in Charge of the Orthopaedic Department, University Hospital, Birmingham.

HORLIV, J. E., M.D., F.R.C.S.Eng., L.R.C.P., Lond., Medical Officer to the Royal Hospital for Children, Nottingham.

JOHNS, W., M.D., F.R.C.S., L.R.C.P., Lond., Honorary Surgeon to the Blackburn and East Lancashire Royal Infirmary.

SANDERSON, J. B., M.D., F.R.C.S., Physician to the Homestead General and North-West London Hospital.

Kinnear.—On July 7th, at Battersea, in his 50th year, Captain John Kinnear, R.A., only son of Mr. and Mrs. Kinnear, of Battersea, and of St. Mary's, Battersea, of which church he was a communicant, and of which he was a member of the vestry.

Williams.—On July 7th, at 102,nedwood Road, Clapham, the wife of Cyril Williams, M.D., L.R.C.P., of a daughter.

Marriages.

Bramhall.—Free.—On July 11th, at St. Stephen's, Altrincham, John Lapwood, of St. Stephen's, Altrincham, Surgeon, and a daughter of the late Captain Bramhall, to Betty Marjory, daughter of Colonel and Mrs. Free, of 44 Queen's Gate, Terrace, S.W. De Burscough.—On July 8th, at Askwith, near Halifax, Yorkshire, Harold John De Burscough, M.R.C.S., L.R.C.P., to Edith, youngest daughter of J. B. E. Bos, Esq., of Burscough.

Hicks.—James, 5, New Street, Holy Trinity, South Hampstead, John Athelstan Braxton Hicks, M.D., M.R.C.S., only son of the late A. Braxton Hicks, Barrister-at-Law, H. M. Court, and of Mrs. A. Braxton Hicks, of 32, Perth Road, W., to Alice Editha, daughter of the late William Lamplugh, Esq., of Esher, and of Mrs. Hall, of Westcliff-on-Sea.

Mellane.—Twelve.—On July 7th, at Frobgs Presbyterian Church, Edward Mellane, Esquire, late of the Bank, to Mary Mlassian, to-day Tweddy.

Waterston.—On July 4th, at 10 Clarendon Crescent, Edinburgh, Robert Wilson Waterston, B.A., M.B., Ch.B., of 28, Eakinde Road, Sheffield, only son of Mr. and Mrs. Waterston, at the request of the Rev. Mr. Waterston, to Dorothy, daughter of Mr. and Mrs. George Waterston, 10 Clarendon Crescent.

Longstaff.—On July 7th, at Crowthorne, Bucks, Roger Wright, M.B., B.S., son of the late William Wright, of Clifton, to Margaret, daughter of Thomas Lee, of Meanwood, Linx.

Deaths.

Bell.—On July 11th, at Upham, Thomas Bell, M.R.C.S., L.R.C.P., J.P. for the County of Rutland, aged 77.

Mackenson.—On July 11th, at his residence, 14 Grassington Road, Hampstead, Charles Mackenson, Surgeon A.M.D.

Thompson.—On July 4th, at 99, Lindsey Mansions, N.W., Margaret Eleanor, the beloved wife of J. W. Wugh, M.D., late of Brighton.

HULME DISPENSARY, Dale Street, Stretford Road, Manchester.
**NOTES AND COMMENTS.**

**Suggested Hospital Equerry for the King.** The kindly interest taken by the King and Queen in the hospitals of the United Kingdom is a matter of general satisfaction. The fact that their Majesties visit a great many institutions of the kind has been followed by the grotesque suggestion that an extra equerry should be added to their staff for the purpose of conveying information upon all special and collateral details of interest. If this suggestion is to be seriously considered, it will be well at the same time to discuss the rival claims of a hundred and one other organisations. If the medical charities are to have their special official mouthpiece and interpreter why should not a similar honour be bestowed upon the Royal Academy, the medical schools, the golf clubs, the Sunday League, the Horse Show and other amusements, the Ascot and other races, the cricketers, the tennis players and a great many other social activities. One fatal objection is that an enormous power of praise or blame would be placed in the hands of the equerry—who, however able, could hardly hope to probe the inner truths of the innumerable charities of the United Kingdom. But perhaps it is not proposed that any but the favoured few hospitals should ever be brought to Royal notice—according to the precedent of the Metropolitan Sunday and King Edward Funds. Were ever so fantastic a Jack-in-office brought into being, he would straightway become an engrossing centre of attraction to the scores of thousands of persons whose interests are more or less vitally connected with this or that particular medical charity.

It is notorious that the clique which practically controls the policy of the Metropolitan Hospital and King Edward Funds deliberately excludes the bulk of the special hospitals from participating in the money subscribed by a generous public for the benefit of the medical charities. It is hardly surprising, therefore, to find the suggestion of a special hospital inquiry coming from a quarter that has always sustained the unjust withholding of grants from the small and the special hospital. It has always been a matter of surprise that the King, who has the courage of his opinions in such matters, should lend the sanction of his name to a system which penalises and starves the small medical charities of London. Why should not the small hospitals have adequate representation on the King Edward’s Fund? Why should they not have a representative of recognised ability and fairness upon the Distribution Committee of the King Edward’s Fund? Is there any adequate reason why a matter of public importance, affecting so closely the well-being of the public and the progress of medical education, should not be the subject of a formal inquiry by the King’s Fund?

**Forcible Feeding Protests.**

A deputation of medical men last week waited upon the Home Secretary to present their views upon forcible feeding of prisoners. As they insisted that Press reporters should be present at the interview, and Mr. McKenna refused to admit them, the matter fell through. Every step of punitive administration throws the onus of application upon someone or other. Unless someone is willing to undertake unpleasant duties of the kind, the whole system of criminal law administration must be abandoned. Perhaps that is what the deputation had in mind. If the Suffragettes are permitted to starve themselves to death in prison, why should not all prisoners of all sorts be allowed to make a bid for liberty on similar terms? Not one of the deputation have suggested an alternative to forcible feeding that fits in with the imprisonment which society has so far found necessary for the preservation of sound law and order.

**Why call it “torture”?** Sir Victor Horsley says it is not medical treatment to preserve life and health. **“Torture”?** If there be not some quibble in that assertion, we fail to see how life is not preserved by forcible feeding of women, who otherwise would starve to death by abstention from food. This sort of loose statement simply confuses the issue. In another sentence Sir Victor says: “It is clear that the statement made from time to time, chiefly by anonymous medical men, that prison forcible feeding is the same as that of hospitals and asylums is untrue.” In what respect does it differ? Similar food, similar apparatus, similar procedures by medical officers and attendants are surely followed in both cases, whether the patients are assenting or refractory! If asylum patients refuse food they are fed perforce, in order to keep them alive. If prisoners refuse to the endangering of their lives, a death at once awaits them. Is the governor of the prison to do with sullen criminals of this kind? Is he to let them die? Is the State to acquiesce in their suicide? Members of the deputation must again be asked to suggest an alterna-
Are all prisoners who refrain from food to be released? Is suicide to be explicitly sanctioned by the State, as it is in certain Eastern countries? Instead of pelting the officers of justice, lay and medical, with volleys of opprobrious epithets, would it not be well for these gentlemen to discuss calmly and philosophically all sides of the tangled social problem that has been raised by a band of women whose bravery one admires while one cannot help lamenting their folly? The suggestion of granting a request demanded under such threats is absolutely repugnant to the instincts of our countrymen. Full female enfranchisement must follow sooner or later, but the question of the forcible feeding of prisoners will not be solved by its attainment. Let the deputation try again.

A National Council and Venerable Disease. Public opinion with regard to the need for instituting an organised campaign against venereal diseases appears to be growing apace. As a direct outcome of the resolutions of the International Congress of Medicine held in London last year, was the appointment of the present Royal Commission. This body has already held a great number of sittings, and the expert evidence given thereat has been published from time to time in abstract in our columns. We learn that it has now been decided to form a National Council for Combating Venereal Diseases as the result of a number of private conferences presided over by Sir Thomas Barlow, K.C.V.O., and which may be regarded as the outcome of the efforts spread over two years by a committee appointed by the Royal Society of Medicine and the Eugenics Education Society. It is understood that the medical profession and of the general public will compose the personnel of the new Council, and that the names of those so serving will be announced later. The suggestion that popular education is probably the most effective method for combating the rates of venereal disease will be received with favour in many quarters, though it must be admitted that the particular mode of imparting instruction will require very careful deliberation. Further details respecting the composition and aims of the new Council will be awaited with much interest by the medical profession.

The Scientific Scavenger. One of the obvious needs of present-day sanitation is the need for more scientific scavenging. The highest achievements in that direction consist in the limited use of dust-tight ash-bins, of covered dust-carts, and of flushing down the streets of certain towns at night. The ordinary practice of brushing the roadway on a dry day sends up clouds of bacteria-laden dust which enters our houses and poisons our food. Why should not the road be sprinkled with some antiseptic fluid, or even with plain water, before the brush is applied? The sagacious housewife has long ago recognised the virtues of spent tea-leaves or damp sawdust in preventing the cloud of dust that would otherwise register the activities of her busy broom. So far as the scavenging of districts is concerned, the chief rock ahead lies in the parsimony of our public health authorities, whose main object is to keep down expenses. Otherwise it would not require a Michael Faraday or a Huxley amongst medical officers of health to devise a sound and practical scheme for scavenging in all its branches upon a scientific basis. Will sanitary authorities kindly note that from an economic point of view money expended in antisepic and generally improved refuse removal would be

saved many times over in diminished sickness, especially as venereal sick persons have to be maintained at the direct expense of the public. The application of the vacuum principle, now employed so successfully upon the domestic scale, might, perhaps, be found practicable in removing dust and refuse in a dry state from our public highways.

We are glad to learn that the appeal

Sir Jonathan Hutchinson's

Museum. (page 56), has been so far successful that among the subscriptions which it has called forth there has been one of £500 from a well-wisher who does not wish his name to appear, and who expresses the hope that his example may be promptly followed by other sympathisers. We remarked in our note of the 15th inst. that "there must be many medical men who would willingly contribute to the preservation and permanent endowment of the Museum out of personal admiration and gratitude to its founder." It appears, however, that the contributions from medical men have been very few. It is surely not too much to hope that some of Sir Jonathan's contemporaries and disciples may yet come forward to aid in the preservation of the Museum which he created, and which would be so fitting a memorial of his genius and philanthropy.

LEADING ARTICLES.

DISABLEMENT BENEFIT UNDER THE INSURANCE ACT.

On the 20th of the present month the last great branch of the National Insurance Act came into operation. It forms an important pillar—if not the corner-stone—in Mr. Lloyd George's essay in public health legislation. Before Monday last the insured worker was entitled to free medical attendance, drugs, and medical appliances; to ten shillings a week for twenty-six weeks when ill; to sanatorium benefit when judged advisable, and to maternity benefit. Henceforth five shillings a week can be claimed up to the age of seventy in the event of permanent incapacity. Those who are fond of quoting the practice of Germany in national insurance will doubtless remark that there the worker becomes entitled to the permanent pension provided he is unable to earn more than one-third of the usual wages. At first sight the German qualification appears far more advantageous to the insured than our own. As a matter of fact, however, the five shillings, when granted to the British pensioner, is not affected by any future income that may accrue, and it is expressly provided that it must not be taken into account by the guardians if an application be made by the recipient for Poor Law relief. The German basis, anyway, was not found to be actuarially possible in the case of the population of the United Kingdom. The latter this week became entitled to disability benefit, temporary and permanent, provided they have paid 104 contributions, corresponding with the number of weeks that the Act has been in operation. There appears to be some amount of confusion in the popular mind as to the scope of disablement relief. For ordinary sickness
benefit the insured sick or disabled person is entitled to ten shillings a week for a period of twenty-six weeks, and at the end of that time, if still incapacitated, that person, provided 104 contributions have been made, receives five shillings a week so long as disablement continues up to the age of seventy, when the old-age pension supervenes. The aggregate indirect bearing of this State provision for the sick poor of the United Kingdom is clearly of great value. It is useless to give medical advice and physic to persons who are physically and mentally handicapped by lack of the ordinary means of subsistence. Good environment is obviously essential to the attainment of a reasonable standard of national health, but the lapse of time alone can demonstrate the success of legislative measures for its attainment. To take a single instance of the value of disablement benefit, let us turn to the case of the domestic servant. There has been no greater outcry against the Act than that by the critics who asserted that good employers provided for their sick servants. Apart from the fact that all masters and mistresses do not satisfy the qualification of goodness, it may be safely assumed that few of them would be willing or able to pension off permanently disabled servants for life. Now that the Act is come fully into operation, it is to be hoped that Mr. Lloyd George will give his serious attention to the hardships inflicted upon certain classes of the medical profession. There can be little question that a large amount of the medical benefit that should be paid for under the Act is obtained free from the special hospitals, whose practice and whose incomes have nevertheless been depleted by the operations of the Insurance Act. The specialist class of the United Kingdom have for many years worked conscientiously and advanced medical science to an extent that is in inverse proportion to their material prosperity. Here is the opportunity of the Chancellor of the Exchequer, who will further the interests of the insured by providing them with special skill that is not available under the panel system. At the same time, by subsidising the special hospitals of the United Kingdom and granting paid official appointments to all legitimate specialists, he will at one stroke take a long step towards the endowment of medical science, the lack of which is a standing reproach to a nation which prides itself upon its commonsense and businesslike methods.

RECURRENT ENTERITIS IN A LONDON POOR-LAW INFIRMARY.

The news that five cases of enteritis have occurred amongst the children at the Southwark Infirmary calls attention to a state of matters that is nothing short of a scandal. Some of our readers will doubtless recall the fact that on a previous fatal outbreak of a similar nature it was found that a number of railway trucks containing refuse from the neighbouring district of Camberwell were habitually shunted and left standing for a long time not far from the infirmary. The inevitable conclusion was that the enteritis was connected with infection conveyed by flies from the trucks to the infirmary. On representation being made to the Camberwell Borough Council that body scouted the suggestion, and actually produced a medical officer’s report to the effect that he had inspected the siding and had seen no dust blowing from the refuse. As well might one expect to see the bacteria of small-pox or of diphtheria being blown about the street. The fact that it would tax the resources of a skilled microscopist armed with a powerful microscope to demonstrate on the body of a fly even the common identifiable pathogenic bacteria formed no part of the report. It was good enough for Camberwell as it stood to use against the innuendoes of Southwark. Later the Local Government Board intervened, and by means of inspectors and correspondence endeavoured to reduce Camberwell to reason. The Local Government Board, however, has failed in its object, for the Camberwell rubbish is still lodged near the Southwark Infirmary, in which enteritis is a recurrent malady. This state of affairs constitutes a grim satire upon our vaunted sanitary administration. The governing body of a crowded London district is unable to protect its Poor-law Infirmary from a dangerous nuisance inflicted by the selfish recklessness of a neighbouring Council. The Local Government Board, the central authority appealed to for protection, has been simply ignored by the offending authority. As Southwark cannot secure Government protection it may be well for them to try what redress may be obtainable through the law courts, although naturally its Council would be unwilling to saddle its ratepayers with the burden of costly litigation until other means of abating so gross a public danger had been exhausted.
autopsy showed that the hydronephrotic sac had ruptured, and that the contents had escaped through the foramen of Winslow. Such cases illustrate the danger of pumping fluid into a diseased kidney when we have no means of knowing either the amount of pressure the tissues will stand. Some of our alleged scientific methods are really contemptible in their rule of thumb regulation, and the sooner they are given up the better. When we have made an accurate diagnosis and know exactly what we have to deal with, a calculated exposure of risk may be justified; but to use dangerous means, whose only raison d'être is our ignorance, is a thing we had better leave strictly alone.

A New Treatment of Pemphigus.
The treatment of chronic pemphigus still constitutes a clinical problem for which a satisfactory solution yet remains to be found. The bacteriology of this affection is still uncertain, for several different organisms have been found, mostly of a coecal nature. Hence the preparation of a vaccine has not been attended with much success. A new method of treatment, recorded in the Dermatologische Wochenschrift, has been outlined by Drs. T. Holobut and J. T. Lenartowicz, of Lemberg, which consists of the spontaneous injection of the contents of the bullae themselves, duly sterilised by heating to 80° C. for half an hour in a water bath. After this period plate cultures are taken, and if no colonies of coecal organisms are found the serous fluid is stored in sterilised flasks, with the addition of 0.5 per cent. of carbolic acid, when it is ready for use as a sort of vaccine. The authors account of two patients, boys of eight and twelve respectively, who had been treated for chronic pemphigus for long periods by various remedies without success. Injections of 1 c.c. of the contents of their own bullae were made once or twice a week, the younger patient receiving six, and the older one twelve injections hypodermically. In both cases the results were excellent, no further outbreak of blisters being observed, while the general health was benefited at the same time. Cases of pemphigus have been recorded which have been benefited by auto-sero-therapy, but the method described above appears to be so simple that it is worthy of trial by dermatologists and practitioners generally.

The Abuse of Accuracy.
Sensationalism governs science no less than anything else. True we have many good men who work in secret, and whose virtue is its own reward. They are appreciated by the few and their work remains caviare to the general. But the man who wants to achieve results—who wants at least to have the credit he deserves—has to exaggerate. Our omnipotent transport union, our only means of communication with the mass of our fellow men, is the Press, and the Press takes no notice of anything beyond incidents, unless it is hit on the head by a metaphorical meteoro-missile of publication. The only hope for publicity. If we want the world to know that we have discovered that two and two make four, we have to announce with two-column headlines and leaded "English" that they make five—or, better still, seventeen. Then we attract attention, and the subtraction of four leaves us left with a residue of too many—perhaps in dignity, but, at any rate, soon. The announcement that the Sanitary Institute Congress has met at Blackpool does not suggest romance. But one of the speakers has stirred the consciousness of Fleet Street. He has banned earthenware and china cups and saucers and glass tumblers and even pewter pots. Towels and napkins of gleaming napery are anathema to him. Paper is the only ware. Cade's condemnation "thou hast built a paper-mill" stands no more. We are to have cups and towels that can be used. Mouse and waistcoat must not be infected. They are perfect theoretically; practically they are hopeless. The fantastic frailty of paper pots and the flabby disintegration of tissue towels will never catch on. They are too uncomfortable, and that is the man in the street who may stand; and the specialist means lost perspective. If we want to persuade the people we must see with the people's eye. They see nothing but fantastic faddism in such proposals, and in these days of democratic divinity we dare not say that the people are wrong.

Manners.
We have all seen small books that tell us the technique of good behaviour. If we have an appreciation for unconscious humour we can extract a good deal of amusement from them. To read them for the humorous passages, the extreme of esoteric enjoyment, probably due to a feeling of supreme superiority that it should be possible for people to be told not to do such un-dreamable things as those which "Lady Camilla" warns us against. Yet etiquette is as old as humanity itself. Since the time of the Pharaohs it seems that a man has to leave the sphere of life that he was born in there must have been new ways for him to learn. Manners may not make man, but man assuredly makes manners. Behaviour ebbs and flows like a tide. The jokes of one generation are the obscenities of the next, and ultra-refinement sends its successors back to a fashionable rudeness. The Canadian Journal of Medicine and Surgery for this month prints some extracts from an eighteen century work on table manners that are not a little enlightening. A certain amount of fortitude tempered with discretion was apparently necessary. "If, unfortunately, you should burn yourself when taking soup, you must bear it patiently and show it: but if, as occasionally happens, the pain is unbearable, you should, before the company perceive what you are about to do, take your plate in one hand, lift it to your mouth, and then, while covering yourself with the other hand, replace what is in your mouth on the plate, and hand it quickly to the lackey behind your chair. Civility demands that you should act politely; but you are not required to commit suicide." Nothing could be better put, and the wisdom is obvious. Again, "After a meal do not pick your teeth with the knife or fork; do not rinse your mouth with water. To see a gentleman expectorating water might give some delicate people a touch of the qualms." We never knew before what "the qualms" were, but we quite understand anyone's feelings on observing such a lapse as our author mentions. We may exclaim with Stace, "O temporal! O mores! O cui bono, cui?"

Sanitary Authorities and Epidemic Diarrhoea.
A circular letter has recently been addressed to local sanitary authorities by the Local Government Board calling attention to the importance of taking all practical measures for the prevention of epidemic diarrhoea and other infectious diseases of infants, and of promoting hygienic conditions in the feeding of infants. The Board desires to emphasise the value of sanitary visits of the homes of children under the direction of the Medical Officer of Health with a view to the removal of conditions in and about their dwellings which facilitate the spread of infectious and other
diseases. It is pointed out that the records of notification of births during the previous months will enable several visits to be made to the homes where they are most likely to be useful, especially in the case of infants from three to twelve months old. The assistance of voluntary visitors might be enlisted in this work, so that co-ordination with any existing institution for the welfare of infants in the district might be secured. The importance of domestic cleanliness is rightly insisted upon, particularly in regard to the preparation and storage of food. At the same time, insanitary conditions outside the house, especially any accumulation of refuse in the neighbourhood of dwellings, should receive prompt attention. The Health and Council. Fresh clothes and bedsheets with flushing cisterns should be substituted for existing closets on the conservancy system, and provided in all new buildings. The distribution of suitable leaflets dealing with domestic cleanliness and the destruction of refuse and flies is a valuable adjunct to house-to-house visitation, while simple instruction on these matters should never be omitted in baby clinics, schools for mothers, infant consultations, and similar agencies.

The Prevention of Hydatid Disease.

In countries where hydatid infection is widespread, the question of prophylaxis becomes one of great importance, especially when sheep-raising is one of the chief industries concerned. A strong movement was put forward at the last Intercolonial Medical Congress of Australasia, held at Auckland, by Professor L. E. Barnett, F.R.C.S. (a), for a more vigorous attack against hydatid disease in New Zealand, for although the Government, through their Departments of Public Health and Agriculture, have done something to combat the evil, much yet remains to be accomplished. So far, it appears that the public in New Zealand have been enlightened as to the nature and prevention of hydatid disease entirely through the individual efforts of medical practitioners. Professor Barnett has been most energetic in his attempts to enlist the interest of the public and also of health authorities in the subject, and he has outlined a scheme of prophylaxis commencing with a brief account of the life history of the Echinococcus and ending with four precise "do's", with regard to the feeding of dogs on raw offal, the drinking of uncleared or unfiltered water that has been exposed to contamination by dogs, the eating of watercress, celery, lettuce, or other uncooked vegetables, unless special care be taken to ensure their cleanliness, and the allowing of dogs to lick hands, faces, plates or dishes. Furthermore, it is suggested that authorities should adopt means to prevent the feeding of dogs on raw offal, to kill off useless dogs, and to provide the owner of every registered dog with printed information respecting hydatid disease as well as for its cure. Additional publicity for these facts might also be furnished through the agency of posters and through the medium of the weekly newspapers. Considering the ravages of echinococcal disease when once it has obtained a foothold in the human body, every possible step should be taken towards the prevention of infection.

PERSONAL.

Dr. Thomas John Jehu, M.A., M.D., F.R.S.E., F.G.S., of the University of St. Andrews, has been appointed Regius Professor of Geology and Mineralogy in the University of Edinburgh, in the place of Professor James Geikie, who has resigned.

Staff-Surgeon Frederick Francis Mahon has been promoted to the rank of Fleet-Surgeon in His Majesty's Fleet.

DR. WILFRED HARRIS, M.D., B.C., Cantab., F.R.C.P., Lond., has been appointed Physician to the Royal Westminster Ophthalmic Hospital.

MR. GEORGE E. STANLEY, M.S., F.R.C.S., has been appointed Assistant Surgeon at the Dreadnought Hospital (Seamen's Hospital Society).

DR. JOHN PARLANCE KINLOCH, M.D., Glas., D.H. Cantab., has been appointed to the new Lectureship in Public Health in the University of Aberdeen.

DR. FREDERICK TAYLOR, M.D., F.R.C.P., Consulting Physician to Guy's Hospital, has been elected President of the Royal Society of Medicine for the ensuing year.

DR. WILLIAM LOUIS RODMAN, Professor of Surgery in the Medico-Chirurgical College, Philadelphia, has been elected President of the American Medical Association.

Sir John Tweedy, F.R.C.S., late President Royal College of Surgeons of England, has been elected President of the Medical Defence Union, vice Dr. Edgar Barnes, retired.

Dr. J. T. Mauclunch will preside at the annual meeting of the Caledonian Medical Society to be held on Friday, July 24th, at 3 p.m., in the Hall of the Royal Faculty of Physicians and Surgeons, Glasgow.

Mr. LyNN Thomas, C.B., on giving up private practice as a Surgeon at Cardiff, has presented to the King Edward VII, Hospital in that city his local private hospital for paying patients, valued at £4,000.

Mr. T. B. Johnston, M.B., Ch.B., Edin., Lecturer on Anatomy in the University of Edinburgh, has been appointed to the newly-created post of Lecturer and Demonstrator in Anatomy at University College, London.

A Portrait of the late Dr. William Berry, for many years Medical Officer of Health for Wigan, has been presented by public subscription to the Wigan Infirmary, of which institution he was for some time Chairman.

Mr. Hugh Scott, M.R.C.S., L.R.C.P., of Lewes, Medical Officer of Health to the East Sussex combined districts, has been placed on the Commission of the Peace for the county of Sussex.

A Presentation was made the other day to Dr. J. Finlay Macdonald, from the Health Department of the Auckland Rural District Council, upon his taking up the medical officership for the South-East Essex Combined Sanitary District.

Mr. E. Fitzgerald Frazer, F.R.C.S.I., of Brighton, was the recipient the other day of a suitable presentation from the local division of the Sons of Temperance in commemoration of his marriage and in recognition of his many years' service as Medical Officer.

Sir James Porter, K.C.B., late Medical Director-General, Royal Navy, will preside at the luncheon to be given in honour of Sir Alexander Ogston, K.C.V.O., late former House Surgeons and Dressers on Thursday, July 30th, at 1.30 p.m., at the Grand Hotel, Aberdeen.

A Presentation of a silver rosebowl was made the other day to Mr. Frederick Gordon Brown, M.R.C.S., on behalf of his fellow officers of the City of London Union as a mark of their affection and esteem on his retirement from the post of District Medical Officer, after serving the citizens of London for a period approaching fifty-two years.
CLINICAL LECTURE ON

SOME FURTHER THERAPEUTIC POINTS.—III.

By HERBERT FRENCH, M.A., M.D.Oxon., F.R.C.P.Lond.,
Physician to Guy's Hospital.

(Concluded from page 62.)

Next let me refer to

The Value of Emetine Hydrobromide in the Treatment of Amebic Dysentery and of Amebic Abscess of the Liver.

It is to Major Rogers, of the Indian Medical Service, that we owe the discovery of the fact that the most important ingredient of ipecacuanha in the treatment of dysentery is precisely that which in the purified form of the drug is thrown away because it produces vomiting. It is this emetine of ipecacuanha which is the essential factor in the cure of dysentery by this drug, and Rogers made the still more important discovery that the hydrobromide and the hydrochloride salts of emetine can be given hypodermically with rapidly curative results, both as regards the dysentery itself and its complications; whilst, when so given, it does not suffer the nausea, vomiting, etc., which crude ipecacuanha is so apt to produce. The drug is now obtainable in the form of little glass balls each containing 1/2-grain of emetine hydrobromide in sterile solution ready for injection, whilst the hydrobromide is supplied in the form of tablets, which can be dissolved in sterile water and thus injected. One does not, of course, meet with amoebic dysentery or any of its complications every day in this country, but in almost every practice a case of the kind turns up, the disease contracted in the tropics, either having persisted until the patient returns home, or else recurring in this country after an interval of apparent cure. In several hospitals, and in one or other of the cases in consultation the curative effects of emetine hydrobromide have been little short of marvellous. In one such patient there had been continuous pyrexia for over two months, the bowels were moved four or five times a day, sometimes with blood, sometimes without; there was pain and tenderness over the liver, and there was the dome-shaped dulness at the right base, together with a friction rub here and other signs pointing to the existence of hepatic abscesses. Quinine, and other remedies, had been tried without any benefit at all, emetine hydrobromide was given hypodermically by Dr. Lacey, of Woolwich, and within a fortnight the temperature had come down to normal, the hepatic signs had almost disappeared, the diarrhoea had ceased, and the patient made a rapid and complete recovery without any operation being done. One can give 1/2-grain of the emetine hydrobromide three times a day, but, in many cases, a single dose per diem is sufficient; at any rate, it is wise to start with one dose a day, increasing this if circumstances indicate the need to do so; it does not seem to produce any untoward effects. It is particularly in the amoebic form of dysentery and in association with the amoebic abscesses in the liver that may follow such dysentery that the emetine hydrobromide does most good, but it has also been tried in the bacillary form of the disease, and one would like to test its effects in those very difficult cases which occur in this country—allied to dysentery, but due to an organism as yet unidentified—namely, English ulcerative colitis. I have not yet had an opportunity of trying it in the latter to any great extent, but perhaps some of you may be able to do so.

The Value of External Heat to Babies Who Are Ill can hardly be exaggerated. In these days of open-windows and open-air treatment, so very important to adults, there is a considerable tendency to think that babies need identical treatment in this respect. This may be true of healthy babies, infants and young children, but certainly does not apply to infants who are sick. Let me try and emphasise this by pointing out that if one were to cool down the external tissues of an elephant, so that they were chilled to a depth of two inches all round the animal it would be some time before this external cold would have any direct influence upon the underlying tissues of the animal, so great is the capacity of the animal is so great. If, however, one were to cool down the external tissues of a baby to a similar extent the viscera must necessarily become affected by the cold almost at once; the only way to prevent their becoming affected thus is for additional calls to be made upon heat production in the child's body, and this entails a repeated draught upon what one may call the fuel of the engine. Sick children take food badly as a rule, and, broadly speaking, anything which can conserve their fuel is good for them. It is probably in this way that oiling the surface of the child's body does good; the oil is a bad conductor of heat and many a case of fever in the middle of a feverish child with an application of oil, not so much by reason of any of the oil itself being absorbed, as by reason of the resultant saving of heat loss and thus of fuel consumption. A greater proportion of the food taken becomes available for the intrinsic service of the body organs. One can do a good deal more towards saving the infant's draught by a similar way by taking care not to expose the body to external cold; if an examination of the chest has to be made it should be done in a very warm room or near a fire and not at what may be called the ordinary temperature of a ward. Infants and young children who are ill often do best in rooms which to healthy adults seem oppressively hot. This is by no means incompatible with proper renewal of the air in the room if the ventilation is seen to properly; it may sound heresy nowadays to say so, but I would rather nurse most sick infants in a hot room even if it were stuffy than in a cold one that was well ventilated. A simple expedient for maintaining the external warmth of a baby, without at the same time, allowing it fresh, cool air to breathe is now used extensively in Guy's Hospital, and this is by means of a cradle over the child, two or three electric lamps being suspended within the cradle. A blanket covers the infant up to the neck; the face is exposed to the ordinary fresh air of the ward, a small cradle-covered by a toy outside the blanket covering the child's body, within the cradle are hung three or four ordinary electric
ights; the cradle is covered with one or more blankets, which are well tucked in round the bed; the electric wire of the lamps passes beneath the covers; the electric switch is turned on and off by the temperature within the cradle watched by means of a thermometer.

I am, of course, speaking of this treatment in a broad general way; one would not use it in conditions of high fever for example, but it is most beneficial in the treatment of marasmus, diarrhoea and vomiting; in cases to collapse, ordinary bronchitis without high fever, and in some cases of fever, similar circumstances; and the heat loss prevented by it does a great deal towards accelerating the child's recovery.

Radium Emanations in Rheumatoid Arthritis and in Diabetes.

A great deal is being written nowadays in connection with cures effected by radium and its emanations, either daily or as a prolonged period. It is difficult to make sure what is real amongst the statements made and what is mere commercial advertisement. I do not propose to enter upon the great value of radium in the treatment of rodent ulcer and malignant disease, but I should like to tell you that I believe radium emanations are of very real value in the relief of certain cases of rheumatoid arthritis, deforming rheumatic arthritis and in some cases of diabetes mellitus. Precisely how the emanations act is quite unknown; it may be that they behave in some way merely as intestinal antiseptics do, or it may be that, like radium itself, they have the power of causing cells and tissues which have taken an erroneous mode of growth and metabolism to return to normal ways. As Consulting Physician to King Edward VII.'s London Radium Institute, I have had the opportunity of watching several cases in which, after other forms of treatment had failed, both chronic joint lesions and diabetes mellitus have been greatly alleviated, if not absolutely cured, by drinking water containing the radium emanations for periods of time. It is some time since it has been generally known that a boy of 15, suffering from ordinary active life with freedom from acidosis and comparative freedom from sugar when previous treatment by diet and by drugs had failed to bring about any particular improvement at all. The difficulty in all these cases is to give statistical proof of the value of the treatment. In many instances where it has been tried to be done, the results have been raised too high beforehand; if, however, the patient is prepared for the possibility of there being no improvement at all one can at least say that there will be no detrimental effect, and now and then a case will be benefited to an extent which, so far as one is able to judge in a broad way, would not have been brought about by other means that we now possess.

The Intensive Iodine Treatment for Phthisis, Peripheral Tuberculosis and Other Chronic Microbial Infections.

The treatment I am about to refer to is very probably familiar to some of you already, but in case it is not I should like to draw attention to it, for it has proved of very material service to a number of cases in which I have tried it, both in Guy's Hospital and elsewhere. Who originated it I do not know; some tell me that it was first devised in Scotland, others that it came originally from Switzerland, but it was Dr. Reeve who first brought it to my notice and who has written about it recently in The Practitioner for September, 1913, p. 391. I was already trying the treatment before that paper was published, and, although it is too early to boast much of the results, there can be no doubt that almost all the cases who have tried it have been benefited by it, and, notwithstanding the comparative naivety of the treatment itself, many of the patients have asked to continue with it after it has been omitted temporarily. Patients, for instance, who have had the treatment in the wards and have afterwards gone home have voluntarily asked to be allowed to go on with the treatment under outpatient supervision. Iodine is now well-known as a very potent germicide, for which purpose surgeons use it locally in preference to almost any other application in preparing the skin surfaces for operations. One cannot, however, administer any large quantity of free iodine by the mouth without
irritating the gastro-intestinal tract and producing vomiting and diarrhoea. One can, however, give large doses of iodide of potassium by mouth, and, after this has been absorbed, one can give chloride water which is also absorbed, the chlorine breaking up the potassium iodide to form potassium chloride and free iodine. The idea of the treatment is to liberate free iodine in this way in the blood and in the tissue juices, so that, wherever the free iodine is present, its inhibiting action on bacteria will be, at least, temporarily increased; even if they cannot be directly killed by the small quantities of iodine present at any one time.

The method of carrying out the treatment is as follows. - The patient takes a single dose of potassium iodide in the morning; say, about 8 a.m., the amount given to start with being generally about 30 grains at a time, though if the patient can take it readily there is no reason why double this quantity or even more should not be used. Sufficient time is allowed to elapse to allow all the iodide of potassium to be absorbed; unless the patient's digestive processes are very slow, generally within about three hours. The potassium iodide will have left the alimentary canal at any rate within six hours, and it has been found by investigation that it does not become eliminated from the system by the urine or elsewhere within twenty-four hours. At 2 p.m., therefore, one can give the first dose of chlorine water, i.e., the chlorine water earlier than this one finds sometimes that the patient is almost immediately sick, bringing up vomit which is blue as the result of the liberation of free iodine in the stomach, the iodine in its turn giving the typical blue colour with the starch in the food. One can repeat it at 4 p.m. and at 6 p.m. Next day potassium iodide is again given at 8 a.m., and the chlorine water repeated at 2 p.m., 4 p.m., and 6 p.m.; and so on for many days or weeks. It is found best to give the chlorine water an hour or a-half more after the last meal; if it is given immediately after food it is apt to produce vomiting, but some milk may be drunk after each dose of chlorine water without detriment. The chlorine water itself is prepared according to the following formula:

\[ R \text{ Potassii chloratis, } 60 \text{ gr. } \]
\[ \text{Acidi hydrochlorici concentrati, } 120 \text{ m.} \]

Place these ingredients in a dry bottle, allow the reaction to proceed for fifteen minutes; and add water gradually to 24 ounces. Dose: one ounce to be taken in plenty of freshly made lemonade.

Certain precautions are needed in connection with it, however, for when newly made there is often far too much free chlorine gas in the bottle to allow of the patient's swallowing the liquid without at the same time inhaling chlorine gas, which irritates the larynx and bronchial tubes and produces oppression in the chest and much coughing and spluttering. It is a good plan to leave the stopper out of the bottle for twenty-four hours or more after the chlorine water has been made, and then for the patient to start at the first attempt with a very small dose such as a teaspoonful or less, diluting it well with lemonade to begin with. The patient will soon learn how little he has to dilute the chlorine water to make it possible for him to drink it, and, after the first day or two, he will also learn how to tell when the chlorine water is, as it were, ripe for ingestion. It is true that a certain amount of the chlorine is lost in this way, but sufficient remains in solution to effect the purpose desired provided the bottle is not left longer than is just sufficient to make it possible for the patient to drink its contents when diluted with lemonade. The dose to be aimed at is about two ounces at 8 o'clock, one ounce at 4 o'clock, and one ounce at 10 o'clock; the object is to give even more than this, but upon the whole doses of one ounce are the most satisfactory. The patient should be prepared, for two separate kinds of temporary ill-effects: the first depends upon the iodism which ensues; in some cases, symptoms of iodism are absent or very slight, but frequently there is running of the eyes and nose, spotting of the skin and some depression which, if the patient were not prepared for them beforehand, would make him certain that the treatment was making him worse. As a rule, however, without any change in the treatment the symptoms of iodism pass off by themselves in ten days or a fortnight, and, although cough and expectoration may be temporarily increased, these presently diminish, the patient's weight increases, the temperature gets less and the patient himself feels that he is very decidedly getting better. The other type of ill-effect that may ensue is frequent action of the bowels, with a tendency to vomiting; if these occur the treatment may be continued for a day or two and then begun again. There will, of course, be cases in which it is found impossible to go on and, as with any form of treatment, there will be cases in whom no improvement results. There are, however, a sufficient number of others in whom the benefit is so marked that I am sure that some of you may wish to try this intensive iodine treatment, and it is on this account that I bring it to your notice.

**Note.** — A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for May is contributed by Robert Saurby, M.D., M.Sc., L.I.D., F.R.C.P.L and J., Professor of Medicine in the University of Birmingham, Consulting Physician to the General Hospital, Birmingham. Subject: "The Treatment of Obesity."

**ORIGINAL PAPERS.**

**DIAGNOSIS IN EVERYDAY GYNÆCOLOGY. (a)**

By H. MacNaughton-Jones, M.D., M.Ch., M.A.O., R.U.I., F.R.C.S.I. and Ed.

In preparing this address I kept carefully in mind the injunction of your President that it should be of an essentially simple and practical nature.

It is the readiness to grapple with the early beginnings of disease that renders the functions discharged by the practitioner of such vital importance to the public health. Throughout all medicine and surgery the maxim "Know thy patient" or "Know thy patient's history" takes first place. The general practitioner is the keystone of the arch of the general health, all the more so now that the "panel system" has come into operation. The hard-and-fast line drawn between the consultant and practitioner has its disadvantages. The unfortunate term "specialist" has come to be interpreted in the eyes of many as implying a degree of ignorance on the part of the one person in whom of all others they should have confidence. They have even come to draw a hypothetical distinction between the "specialist" and the general practitioner.
and "consultant," placing the latter in an inferior position, should he not exhaust his whole mental resources in dealing with one small portion of the human mechanism.

Unfortunately for the application of this idea, that machinery is not constructed on the plan of the motor car. Though in common speech we use terms that would imply there is some analogy, this is incomplete at every point. Many years since Lethaby said that the heart was a more economical force than the steam engine in the foot pounds it raised in proportion to the fuel supplied. But you can remove the motor engine, and clean or repair it: you cannot do this with the heart. When your car is "overhauled," it can be taken to pieces, and each part can be studied separately; not so with the human machine when it comes to you for its overhauling.

Gynaecologists, fortunately, have to deal largely with parts that are not actually essential in the running of the human motor. Uterus, appendages, and appendix may all be sacrificed either at the same or different times, and yet, though not a "complete" woman, your patient may be a healthy one. I know some such in perfect health to-day from whom all these parts have been taken years ago. On the other hand, every part of your motor machinery is essential to the running of your car.

This explains why early indications of disease in the pelvic viscera are often trivial with. Pain, the usual warning of coming breakdown, is often absent, or, if present, is counteracted by sedative or hypnotic remedies, or some palliative means are adopted to stay the unpleasant discharge, the frequency of micturition, the sense of dragging, the loss of apprehension of the possibility of quantity, some reflex neurosis in an organ of sense or digestion, or through the circulatory current in the heart. Besides, in different women the capacity to bear pain varies greatly. A trivial degree will cause one to complain, whereas in another the power of endurance and the dislike to attract attention or to cause trouble leads to concealment up to the breaking point of health. Meantime, the early evidences of malignant changes in some part of the genitalia are overlooked, the leper is watching, the vaginal ulcer is spreading, the cervical erosion is deepening, the endometritis is becoming supplicative, the degeneration of the myoma uteri is setting in, tube and ovary are becoming involved. A little later on, and hydro-salpinx or pyo-salpinx is forming, the ovary is becoming cystic, and infection is spreading either from appendix to ovary or in the reverse direction from ovary to appendix.

Surgical assistance is the next court of appeal. There is no highly coloured description. It is what every practical gynaecologist knows to be constantly happening. The detection of the earliest signs and symptoms which indicate departure from the normal processes and interchanges in cells, tissues, structures and parts, is in the hands of the practitioner. Is it not safe to say that if they were recognised, and curative means adopted at this stage, a very large percentage of mutilating and life-risking operations would cease to be necessary. Their detection by careful first examination in a great majority of cases is not difficult. Treatment is generally simple, and the lines of action are clear.

The facilities for the acquisition of practical knowledge in all departments of medicine and surgery have so developed that any and every industrious and ambitious student has within his reach, during his five years of study and those that immediately follow, ample opportunities of mastering all the therapeutic and technical operative steps required in dealing with the ordinary affections embraced under the head of gynaecology.

There is no more characteristic advance in modern surgery than the assumption of independent action by the practitioner in the operative procedures which come within the reach of his experience and skill. The field for such an exercise has greatly increased in recent years. Out of the competition between the consultants, the practitioner has reaped his advantages in postgraduate courses and polyclinics. You will supply the term that is applicable in the undertaking of any procedure which is not justified by the operators’ knowledge and experience.

We come now to consider the most important step in the diagnosis of those abnormal conditions which are every day presenting themselves for detection and treatment. This is, the first examination of the patient. I press on you that for your own safety as for her benefit, whenever possible, a short note should be made at the time of her history in relation to age, the catamenia, pregnancies, abortions, previous hospital action, evidence of bladder trouble, discharges, and the nature, character, and situation of pain. With such knowledge the object and scope of the examination in a large proportion of cases may be determined beforehand. Of special importance is the time of occurrence and the character of the last menstrual period. In every suspicious case we have first to exclude the possibility of pregnancy. If doubt arises, there should be some witness of the test you apply. The barren rat may enter a trap. In the instance of a virgin, the resort to a vaginal examination will depend on the nature and urgency of the symptoms, or the failure of past remedies to relieve these. Here, judgment and discretion must come in. Do not go on treating a sufferer from persistent primary amenorrhoea with emmenagogues who has an atresic vagina, or send a girl to Schwabach or Spä in whom the genitalia are absolutely negative! As a rule, obstinacy and urgency in symptoms must decide the practitioner whether essentially a case in which an anaesthetic should be availed of. No thoroughly satisfactory decision can be arrived at without it.

Let us here briefly consider the conduct of the examination without an anaesthetic, and what we learn from it.

It is this first examination which frequently determines diagnosis and treatment. Carelessness in abdominal palpation, percussion, and auscultation will leave undetected the loose kidney, which you will not be wrong in making your first quest for in your abdominal search; we overlook the sense of resistance, dulness, or fluctuation, and the sensitiveness caused by pressure in some part, or direction, as in McBurney’s or Lanz’s points indicative of appendicular complication; the characteristic resonance of the flanks in differentiating ovarian cystoma from ascites; feel or detect contraction of the pregnant womb, confirmed by associated signs, in the exclusion of pregnancy in the case of myoma, while we keep in mind the occasional co-existence of both of these states, as also the presence in a large fibroid of a misleading blunt which may be confounded with the
uterine souffle; the relative sensitiveness in the two inguinal regions, and the detection in either of any swelling or the presence of enlarged glands.

At the right side we keep appendicular, ovarian, and ecalc complications in view; at the left, ovarian, sigmoid, and occasionally also appendicular.

We remember that there is such a thing as left-sided appendicitis, and an appendix carried over to become adherent to the sigmoid, as also appendiculo-ovarian complications at both sides.

Coming to the external genitalia, even the labia may lead us into oversight or error. Such a chance may happen to the most experienced. He is a bold or extraordinarily fortunate man who cannot recall occasions in which too hurried a conclusion has led him to give a wrong opinion in gynaecology.

A hydrocele of the cord or a cystic Bartholin's gland may be mistaken for a hernia, or vice-versa. The examination of the urine may be overlooked in pruritus vulva, and the diabetic or other source of the irritation pass unrecognised.

The dorsal position is the only proper method for the examination of the introitus.

At the outset we may find an introitus closed by an imperforate hymen. Readily we detect the source of painful or frequent micturition in caruncle, some prolapse, procidentia, or a vaginal cyst at the outlet. New growths or ulceration, whether benign, malignant, or specific, are at once recognised; so is the characteristic appearance of the mucous surfaces often present with malignancy, as also the white leathery look of leukoplasia. Note is taken in passing of the anal opening, the presence of hemorrhoids, and the integrity of the perineum, the deficient character of the latter has its common association in a relaxed introitus, a vaginal prolapse, a cystocele or rectocele.

It is well to make the preliminary vaginal examination in the Marion Sims' position, the pelvis slightly elevated, the back of the left hand on the right scapula, and the right arm over the couch, with the head turned to the left. With the antiseptic tube of formalin or cinchon cream or lard, the old filthy practice of the jet of vaseline used in common for different cases has disappeared. In every instance where a final decision has to be arrived at the bowel and bladder should be emptied beforehand.

A word of caution is here necessary. Any abrasion on the examining hand will suggest the use of the rubber glove, and in all cases of suspicious discharge and sores this precaution should be taken.

I have known some sad cases of infection and blood poisoning arise from its neglect. I need not say that careful and thorough cleansing of the hands should follow each vaginal examination.

This vaginal search excludes erosions, ulcerations, and growths in the vaginal wall, as well as encroachments from the rectal and vesical sides.

We judge the character of the portio, its length, shape, hardness or softness, the size and feel of the os uteri, and the mobility or fixation of the uterus. We ascertain the presence of any swelling in either fornix, a prolapsed or sensitive ovary or swollen tube. Should any such condition of uterus, tube or ovary be discovered, the dorsal and bi-manual examination should follow.

The next and concluding step is the bi-manual examination which includes the recto-vaginal, recto-abdominal, and recto-vesical. Here the dorsal lithotomy position, with the buttocks well to the edge of the couch, and leg-strings or rests, are essential. Our accessories are a duckbill speculum, uterine hook, different sized tubular specula, and the uterine sound.

If we have satisfied ourselves fully by a process of exclusion in the previous lateral examination, on the points mentioned, all that we may require to see is the condition of the external genitalia and the state of the cervix. For this the tubular speculum only is required. Otherwise, the duckbill is brought into requisition, and the uterus, unless fixed by adhesions, or retracted by growth, being pulled off slowly the observer will observe the character of the erosion, the presence of a polypus, the nature of a laceration, or the indications of malignancy, are determined.

All evidences of pregnancy having been excluded, the length and direction of the uterine canal are found by the uterine sound. Withdrawing the speculum, with two fingers of the left hand in the vagina, and the right on the abdominal wall, we estimate the size and mobility of the uterus or growth, to direction, and mobility.

Searching either forearm, we satisfy ourselves as to the condition of the ovary and tube. In any case in which there is a swelling or tumour in Douglas's pouch, we make a combined rectal examination. Here, especially, there is a call for gentleness and slowness. The well-greased finger is slowly introduced, and the sphincter gently dilated. It is then carried well up, so as to reach the adnexa, and the suspicion of an ovarian or tubal enlargement is confirmed. If there be a tumour behind the rectum, such as an osteo-sarcoma of the sacrum, it will be readily detected. It is well at the same time to make a bi-manual examination with the other hand in the vagina; and, lastly, the recto-abdominal method which will help to throw light on any possible complication of a uterine or ovarian growth. If there be a suspicion that the uterus is ill-developed, or absent, the rectovesical test with the sound in the bladder and the finger in the rectum will determine this.

Long as it has taken, to give a trial in detail this examination, the practice it can be conducted in a very short time. When completed, we have detected or excluded all the greater changes in the pelvic visceras. We have taken note of the source, quantity and nature of the discharge, retaining if necessary some for microscopical and bacteriological examination. We have satisfied ourselves as to the condition of the external and internal genitalia, and, most important of all, the presence or absence of those signs which are indicative of existing or threatening malignant change. Follow this up with an examination of a catheter specimen of the urine, and all the essential facts involved in diagnosis will have been elicited.

In regard to the bladder, every now and then cases occur in which the cystoscope is necessary to decide the cause of the vesical pain, cystitis, or hematuria. With any care stone in the female bladder cannot escape detection. Obviously if renal or urinary signs and symptoms point to the possibility of a calculus in the kidney or the ureter the X-ray should be availed of to detect or exclude it.

There are not a few cases in which it is absolutely necessary to resort to anesthesia in order to arrive at a satisfactory conclusion. In nervous and sensitive women who involuntarily resist, when the abdominal muscles tighten and render the wall tense and rigid; where there is a large pendulous and fat abdomen in which palpation and bi-manual
touch is difficult; in cases in which we require complete relaxation and very thorough bi-manual exploration, so as to decide some uncertain point or suspected complication. Whenever such difficulties or doubts exist an anaesthetic is absolutely needed.

If we have excluded the genitalia and lower rectum, yet are still in doubt as to the cause of pain, a more careful search under anaesthesia may disclose a swelling in the sigmoid, and call for a sigmoidoscopic examination. In all such doubtful rectal cases, it is well to see the character of the stools on a few occasions. We may find some material evidence to assist us in pipestem or ribbon-like motions, and the presence of blood or mucus.

If trust I have not taken up your time uselessly in recalling to your minds the vital importance of an early, complete and correct diagnosis. One final word. Do not belied into the error, when you discover an uterine or adnexal disease or some other error of function in the genitalia, of ascribing to this every other ill from which the woman suffers. The organs of the body, though federated by the circulatory current, nerve distribution and connecting links, have each an autonomy of their own.

The human body is essentially a perfect democracy in its system of government. The smallest ganglion or gland claims independent freedom and liberty, though recognising the right of its local centre to control its action, while the latter obeys the central government. Consequently, each organ has to regulate its own governmental system, the responsibility of rectifying its special insanitary states. We have to realise this in the general treatment of the woman. He is the soundest gynaecologist who includes in his review of her pelvic organs an inquiry into the health of any other to which symptoms point as demanding attention.

At the same time there are reflective disturbances of function of organs remote from each other. The kidney is seriously involved, and such uterine reflexive neuralgeses are not of uncommon occurrence. Hence we have to discriminate between the functional error due to such neuralgeses, and that which follows an organic change. A woman with a retroversion of the uterus suffers from sickness and headache. The former symptom may or may not be a neuralgic; the latter may be consequent upon an undetected error of refraction.

I conclude with my favourite aphoristic motto, "Bene diagnoscit bene curat." (A lantern demonstration illustrative of several of the points touched on followed.)

A CASE OF BANTI'S DISEASE.

By F. J. BAILDON, M.B., C.M.,
Senior Hon. Medical Officer, Southport Infirmary, etc.

On February 13th, 1913, E. W., a young girl, aged 15, was admitted to the Southport Infirmary with the following history.

She had been working in a painter's shop where there is a stove kept hot in the daytime. On leaving work one cold night about a fortnight previously she got a chill and had some shivering attacks. She went to bed and sent for her medical man, who considered the case to be one of acute Bright's disease. He treated her for this, and she was sent into the Infirmary as suffering from this complaint.

On admission her temperature was 101.3; pulse, 128; and respirations, 28. Her face was puffy and white. There was some blood in the urine, but no casts were found, and unless blood was present there was no albumen. The abdomen was distended with fluid to such an extent that it was impossible to palpate any of the abdominal organs. She was put on a mild diet, dry-cupped over the loins, and a mild diuretic mixture prescribed.

No improvement followed, but the blood in the urine diminished in amount, and its presence became intermittent to some extent. The child had no pain, and did not appear much distressed. The abdominal distension increased so much that on February 22nd a Southey's tube was inserted, and in a few hours eleven pints of clear serum were drained off. Two days later another five pints of serum were drawn off. The removal of this large quantity of fluid made palpation possible, and a large mass was detected in the left hypochondrium, which was tender on pressure and which had a sharp border. Later on the splenic notch could be made out. No enlargement of the liver could be felt.

The girl was evidently very ill. A large, deep ulcer with a sloughy black base appeared inside the right cheek, followed in a day or two by a similar one inside the left cheek and a smaller ulcer on the tip of the tongue. These had the appearance of cancerous oris, but the external skin was not affected, there was no haemorrhage, nor was there any offensive odour. During the last few days of February she complained of pain in the rectum, and a painful red patch appeared at the side of the anus. About this time some oedema round the ankles was observed. As will be seen from the chart, her temperature ranged from 99 to 102.6, and it averaged about 101. On March 2nd, some large blood-clots were passed from the bowel, and shortly afterwards death took place.

Permission to make a limited post-mortem examination was obtained. The spleen was much enlarged and weighed 1 lb. 5 oz. The liver was cirrhotic and weighed 1 lb. 12 oz. The
right kidney was swollen and pale on section. There were some adhesions round some of the abdominal organs. No enlarged glands were found. There was no jaundice. No examination was made of the blood, but the patient was clearly anaemic, and the anaemia together with the enlargement of the spleen and the cirrhosis of the liver form the combination of symptoms known as Banti's disease.

A full account of splenic anaemia and its terminations, one of them being known as splenomegalic cirrhosis of the liver or Banti's disease, may be found in an article by Dr. Lyon in the "System of Medicine," edited by Osler and M'Crae. It is not a very common complaint, and nothing is known of its causation. Dr. Buchanan describes the changes in the composition of the blood in his book, "The Blood in Health and Disease," and I refer to these works for a complete account. One or two points are of interest in this case, however, and may be mentioned. First, the very short history of what is considered to be a chronic disease, the history in some cases extending over many years. Acute cases are mentioned, but looked upon as doubtful. This girl when admitted had the appearance of having been ill for months instead of days, and the liver and spleen give the same impression, as may be seen from the illustration. This girl was at work and apparently well five weeks before her death. Secondly, the disease is much more common in males than in females. Dr. Lyon records 17 cases, of which only 8 are females. Thirdly, although cases are recorded in children, it is mainly a disease of middle life. Fourthly, the occurrence of a tebrile temperature is said to be unusual.

It would appear as if an enlargement of the spleen with anaemia and cirrhosis of the liver may exist in a quiescent stage for a long period of time or until some intercurrent complication, such as a chill, disturbs the balance of the organism and precipitates the end. We know that advanced cirrhosis of the liver may be present without ascites. H. G. Sutton, in his "Lectures on Pathology," says that the most extremely cirrhotic liver he ever saw was in a man who met with a fatal accident when at work, and there was not a sign of dropsy. A sort of compensation may arise which enables the individual to maintain a reasonable state of health, but which soon collapses when the balance is upset.

I wish to express my thanks to Dr. Hearn for the careful notes he took for me. The liver and spleen are in the collection in the Thompson-Yates Laboratories, Liverpool.

**WHY MUST WE ALWAYS THINK OF SYPHILIS?**

**By Professor P. SPILLMAN, M.D., [Specially Reported for this Journal.]**

We know by experience that syphilis is no respecter of persons or social distinctions, that—venereal or non-venereal—it crops up here, there and everywhere, that innocent victims are legion, that the disease is hereditary and may be transmitted even unto the second generation, that many victims are ignorant of their misfortune—so much
so that in at least 15 per cent. of tertiary lesions the mode of infection remains a mystery.

In both hospital and private practice I meet with many cases illustrating the possibility for always bearing in mind the possibility of syphilis in mind. I will mention a few of them as object-lessons.

We will commence with the respiratory apparatus. What is commoner than pulmonary tuberculosis, and what can be more discouraging than the diagnosis of a confirmed lesion? Fortunately, in a certain number of cases, things are not always as hopeless as we are in the case of a man with well-marked hereditary, 40 years of age, who, three months after an attack of typhoid fever, presented symptoms of disseminated sclerosis. We suspected syphilis, and after the third injection of grey oil the symptoms cleared up.

In times gone by we did not recognise the possibility of syphilic polynuritis. An instance in my wards published by Dr. Etienne shows the remarkable efficacy of treatment, and nowadays the number of cases of neuritis cured by mercury is very great.

Similar good results are obtained in paraplegia, even when syphilis is denied or has been overlooked. We can recall the case of a woman, 80 years, who had been treated by many physicians with various remedies for years. Auscultation revealed signs of infiltration throughout the right lung, with no percussion at the apex. In spite of a negative bacteriological examination, the case looked unprospective. This patient, however, presented traces of serpiginous syphilides on the legs and lower part of the body. She had been contaminated early in her married life by her husband (who later manifested cerebral and spinal symptoms). Interrogation elicited complete curement and an alleviation of symptoms. The case cleared complete and syphilis was ruled out. With a gain of six months a weight of 25 lbs., and recovery has been maintained for the last three years.

A similar case is that of a medical man, 32 years of age, syphilitic since six years, inadequately treated by means of pills. His condition was hopeless, the loss of flesh, hemoptysis, and signs of extensive softening. This made us suspect syphilis, and he was put injected with grey oil, under which he quickly recovered. It follows that we must always bear in mind the possibility of pulmonary syphilis, and even if tubercle bacilli be found in the sputum the lesions may be mixed, and therefore in part susceptible to treatment.

Turning to the circulatory apparatus, we meet with cases of aortitis, apparently due to other causes, which nevertheless immensely improve under mercury and iodine. Syphilis is certainly responsible for 70 per cent. of cases of aneurysm, and this information suggests a more hopeful means of dealing with them than is usually supposed.

I may add that many otherwise inexplicable cases of anaemia do better on mercury than on iron simply because their origin in reality is syphilitic.

I have never come across such striking cases as those reported by Andral, Fournier, Dieulafoy, etc., of the success with treatment of profluse haemorrhages due to loss of mercury, and iodine when due to breaking down gummati, but I have seen cases of pseudo new growths of the liver cured by anti-syphilitic treatment.

A girl, aged 26, following an injury, presents what seem to be ordinary exostoses, but they proved to be manifestations of delayed healing by syphilis, and yield to treatment—this without any traumatism—when it was abandoned.

Lesions of joints apparently caused by injury or due to tuberculosis may be syphilitic. Dr. Louis Stillmann presented an instance of the kind before the Medical Society, and I myself have shown a case in which bilateral hydrosyphilitis proved to be due to syphilis in a girl who was also suffering from a lesion which looked like a tuberculous gumma. It is unnecessary to add that treatment was followed by prompt recovery.

Lesions of mucous membranes are those in which the patient derives most benefit from treatment based on the suspicion of syphilis. I have published many cases which bear out this statement.

How many patients, long and vainly treated for lupus of the pharynx, have been cured in a few days? In some instances they did not come under treatment until after destructive lesions had worked havoc, but in many others the healing was complete. Some of these patients made a point of coming to see me at regular intervals without waiting for any actual lesion.

It is in respect of the cutaneous and nervous systems that syphilis reserves the greatest surprises. As a case in point, the case of a man with well-marked nervous heredity, 40 years of age, who, three months after an attack of typhoid fever, presented symptoms of disseminated sclerosis. We suspected syphilis, and after the third injection of grey oil the symptoms cleared up.

In times gone by we did not recognise the possibility of syphilic polynuritis. An instance in my wards published by Dr. Etienne shows the remarkable efficacy of treatment, and nowadays the number of cases of neuritis cured by mercury is very great.

Similar good results are obtained in paraplegia, even when syphilis is denied or has been overlooked. Lesions of joints apparently caused by injury or due to tuberculosis may be syphilitic. Dr. Louis Stillmann presented an instance of the kind before the Medical Society, and I myself have shown a case in which bilateral hydrosyphilitis proved to be due to syphilis in a girl who was also suffering from a lesion which looked like a tuberculous gumma. It is unnecessary to add that treatment was followed by prompt recovery.

Lesions of mucous membranes are those in which the patient derives most benefit from treatment based on the suspicion of syphilis. I have published many cases which bear out this statement.
SYMPHIS nine months before, and ultimately be- 
drifted into my consulting-room, where I manage to 
effect the fact, and under such circumstances he 
might be added in a few weeks.
Numerous, too, are the cases of cerebral arteritis 
thus cured, and these cases are the more typical 
in view of the absence of objective signs.
I stated earlier that the nervous system and the 
skin afford a rich harvest of cases cured by treat- 
ment instituted in spite of the absence of evidence 
of syphilis. I have noted a large number of ulcer-tuberculous 
lesions and ulcers, which promptly cleared up under specific treatment. It 
would be easy to multiply these instances, if in- 
stead of limiting myself to my own cases I dipped 
into the copious literature on the subject. The fact 
which I wish to impress upon you is that syphilitic 
disease is very "simulating" disease, that not only may 
it closely resemble other well-known diseases, but 
its own pathognomonic lesions may be curiously 
absent. Then, too, we cannot rely upon the co- 
operation of our patients, since for various reasons 
they may leave us in ignorance of their past patho- 
ological history, of which, for that matter, they may 
exceptionally be the ignoramuses. Since we 
know that many diseases apparently of quite a different 
nature may in exceptional instances be due to 
syphilis, it behoves us to be on the lookout for 
it and to bear in mind that even when syphilis is 
not alone involved, anti-syphilitic treatment will do 
good by relieving the organism of at least one source 
of depreciation.

CERVICO-FACIAL ACTINOMYOSIS.

By A. PONCET, M.D.,
Professor at the Faculty of Medicine of Lyons.

Gentlemen,—For the second time this year, and 
at a short interval, I present to you a case of cervico-
facial actinomycosis. You ought indeed to familiarise 
yourself with an affection which is fairly common 
and but too often passes unrecognized, especially by 
practitioners who have not had the good fortune to 
meet with clinical examples thereof, yet it is one in 
which a correct and early diagnosis is all important, 
since without it we are unable to bring to bear the 
therapeutical resources from which we are entitled 
to hope the best results.

Our patient was 21 years of age. She presents 
nothing of interest in her personal or hereditary ante-
cedents. She comes from Bresse, a district with a moist 
climate, where they grow cereals. Dr. Berard and 
I have placed on record several cases of the same 
disease precisely from this part of the country.

As a farmer's wife, our patient owns and comes into 
contact with cattle, especially cows. You now are all 
of you aware of the frequency of actinomycosis in 
the bovine race, and of the fact that the fungus develops on 
the straw and other vegetables on which these 
animals feed. These are points to be noted because 
they may put us on the track of the probable origin of 
the disease which brings the patient to my consulting-
room. From the first of July to the last August, when she began to complain of pain in 
the left half of the lower jaw, more particularly 
behind the angle of the jaw. A swelling made its 
appearance, and as the tooth, a recently decayed tooth, 
was not visible, I naturally assumed that the trouble 
was due to them. This gentleman, is a very easy 
man to make, especially as decayed teeth and actinomycosis are often associated. As a matter 
of fact, decayed teeth favour inoculation with 
the infection of actinomycosis. In such cases we often find 
ulcerations of the bucal mucosa, the edges of the gums 
are affected, the alveolar cavities are gapping and offer 
so many doors of entry for the fungus of actinomycosis 
that it is not strange that the process took hold in the 
month, and once it has gained a footing in the tissues it thenceforth multiplies at its ease.
Whatever may be the part played by decayed teeth

in actinomycotic infection in general, certain it is that 
in this particular instance the trouble was attributed 
solely to the bad state of the teeth, and this unfor-
tunate assumption dictated the treatment. Three 
decayed molars, including one wisdom tooth, were 
extracted, and the mouth thoroughly washed out. We better advised, 
fortunately this was only apparent, for a few days later 
the pain and functional disturbance reappeared, the 
trismus got worse, and so did the sub-maxillary 
enlargement.

This peculiar course is very significant, and I would 
take you to take particular note of it. In accidents 
of dental origin extraction of the teeth usually puts an 
end to the trouble, but in actinomycosis only temporary, 
transient relief is obtained. I would indeed go 
so far as to state that after adequate and pro- 
cine the symptoms recur with enhanced activity.

The fungus finds an excellent cultivation medium in 
the tissues damaged by the extraction. So much is 
this the case, that if there be the slightest suspicion 
of the case being one of actinomycosis it behoves to be 
cautious how we traumatise the mouth.

Therefore, in spite of, possibly indeed on account 
of, the unfortunate intervention of the dentist, the 
local state was far from auspicious, and I got 
the patient sent to the Croix-Rousse Hospital under Dr. Delore.

By that time it was plainly a case of actinomycosis.

There was an extensive swelling on the cheek and in the 
sub-maxillary region, the tumour was red, livid, with 
ulcero-tuberculous foci and of cardboard consistency, 
without any tendency to suppuration.

The clinical signs of the affection became still more evident in 
the course of the next few days. Here and there appeared 
fluctuating pimples standing out the tumour. By bringing them there escaped, not pus, 
but a characteristic blood-stained serous fluid, con- 
taining tiny puriform masses, like yellow grains, and 
microscopical examination clearly established the 
actinomycotic nature thereof.

I may observe that although positive microscopic 
results confirm the diagnosis and place it beyond 
question, the absence of the specific elements does not 
exclude the diagnosis, because it is sometimes 
very difficult to demonstrate their presence. Especially 
is this the case after the iodine treatment has been 
commenced; in fact, all trace of the yellow grains has 
been known to disappear after six days' treatment.

But let us return to the patient. As you see, she 
presents a very extended tumour occupying the 
left maxillary and genial regions. It is of considerable 
size, and, owing to its bright colour, it looks inflam- 
atory, so much so that a careless observer might be 
tempted to think a knife had been used, or that 
the tooth, which might be considered a foreign body, 
was acause of inflammation. Such a misapprehension 
would, of course, lead to the removal of the offending 
object, and the pus might escape. On palpation, this tumour presents a peculiar, 
cardboard, uniform hardness, and there are no soft spots. I need hardly point out that 
the actinomyotic inflammation of four months' standing 
would long since have broken down, and this slowness 
of evolution, this indisposition to suppuration is peculiar 
to actinomycosis.

Then, too, this mass has ill-defined margins; the 
thicker, extends vaguely in all directions, imper- 
ceptibly merging into healthy tissue. Over the zigyo-
matic arch you see some purules like those already 
opened. These we will incise before you, and 
you will see the blood-stained pus. There is already 
other tumour, a tumour containing puriform flakes of fibrin, 
which must be distinguished from the yellow grains 
peculiar to actinomycosis. There is no glandular 
enlargement and no temperature.

The function of the mouth is normal and especially of 
pronounced sensibility, the patient has the greatest difficulty 
in separating the jaws, speech is interfered with and 
mastication impossible. This symptom is pathogno-
monic.

She has been taking iodine, and already it is begin-
in to produce its effects. Though the swelling has 
not yet undergone any noteworthy change, the trismus 
is less rigid and the teeth can be separated to a greater extent.

With regard to treatment, the superficial, breaking-
down lesions have been opened, curteted and painted

THE MEDICAL PRESS. ORIGIPAL PAPERS.

September 22, 1914.
with tincture of iodine. She is also taking iodide of potash internally in doses as large as she can tolerate. In refractory cases it is well to associate the iodide treatment with the administration of arsenic, preferably in the form of an organic compound such as the cacodylate of sodium. Double strength of the latter in the course of a short time we shall see very tangible results, and in the meantime I advise her to get out as much as she can in order to expose the lesions to the sun because the parasite of actinomyces, like most of its kind, seems to be particularly sensitive to the direct action of the solar rays which greatly hinder its development. By this means we may confidently hope to cut short an affection which would otherwise infallibly go from bad to worse. I have been able to show a whole series of photographs of persons suffering from actinomyces, inter alia, that of a young man, also from Bresse, who comes to us now and then for inspection. He, too, is suffering from angulo-facial actinomyces. His case is identical in almost every respect with the one I have just demonstrated before you except that in this instance the mischief is limited to the characteristic tunefaction and trismus. Now that you have seen at least one example of the disease in a living subject, these photographs will enable you to remember the various forms in which the disease may present itself. Looked at as a whole the appearances are very characteristic, but looking at the cases separately, the possibility of a given maxillary swelling being due to actinomyces must occur to you. Should your suspicion be excited, nothing is easier than to verify the diagnosis and institute the specific treatment, and any failure in this respect would reflect discredit on the practitioner.

OPERATING THEATRES.

FRENCH HOSPITAL AND DISPENSARY.

ABSCESSES OF THE DORSUM OF THE PENIS, WITH COMPLICATION OF SIMPLE SORES UNDER THE PREPUCHE.—The patient, a cook, aged 21, operated on by Mr. de Méric, had contracted sores in South America, which had been treated on board ship by cauterisation and lotions. The sores came on four days after connection, but the man said he had been with the same woman more than two months before when the ship was at Buenos Ayres. On admission to the French hospital, Mr. de Méric had the sores. Fifteen days after admission a small abscess appeared on the dorsum of the penis, which discharged freely through a small opening. Another abscess soon formed at about an inch from the first, and it was evident they were burrowing beneath the skin. The glands in both groins were indurated but not enlarged. A Wassermann was negative. Mr. de Méric freely opened the sinus between the abscesses, passing first a director, and slitting up with a curved, sharp-pointed bistoury. Mr. de Méric said the case was interesting in view of what might occur in the subsequent history. Here was a man with a long prepuce, which, however, he could easily get back without doing himself or the chances any injury. These last, from the patient's account, had shown themselves four days after connection. The glands in both groins were indurated but not enlarged; they felt like marbles. There was no eruption, no sore through the course, no syphilis, no enlargement of the groins, no lancinating pain, no fever, no general feeling of unwellness, etc. Yet the chances, as far as one could see them on the inner side of the prepuce, looked syphilitic, though the induration was more of the doughy kind felt in simple sores than the absolute or even the paroxysmal real syphilis. The Wassermann was done in the hospital by Dr. Eckenstein and the result was negative; for this reason, Mr. de Méric pointed out, he only slit from side to side in this manner in order to deal locally with the sores; this he would not once have done had the Wassermann been positive. The negative Wassermann pointed to the sores being simple and not syphilitic, therefore any slitting up of the foreskin would have been followed by the incision taking on the form of a simple (or what in England is mis-named a soft) sore, and by the whole of the foreskin being converted into one large sore. With reference to the negative Wassermann, it might be said that since the patient had been in the hospital he had been taking protoiodide of mercury orally, and in the course of a week or ten days was hardly sufficient to convert a positive into a negative Wassermann, supposing the chances to have been syphilitic on admission. The abscesses and fistula were on the dorsum of the penis, and as far as possible every precaution was taken to prevent any discharge from the sores under the prepuce coming into contact with the small incision connecting the fistula; still such isolation of the dorsum of the penis would be very difficult in view of the constant change of the dressings. At any rate, the opening up of the fistula was an absolute necessity, in spite of the negative Wassermann, and, assuming that the incision did become contaminated, which was very likely, the diagnosis would be made quite clear according to whether further sores developed on the dorsal incision or not.

Four days after operation the incision between the abscesses had formed a large keloid-looking sore, thus proving as far as possible that the sores under the prepuce were simple or soft and not syphilitic; if the sores had been of the latter variety the incision would have remained a simple incision, and an incision would have formed on it, for, as Mr. de Méric pointed out, the discharge from a syphilitic chancre when inculcated on the same individual produced no result, whilst the pus from simple or syphilitic sores inculcated on the same person gives rise to similar or more intense sores, which very often take on themselves a keloid character. This last characteristic Mr. de Méric said he had frequently seen many years ago when he carried out a series of operations for syphilis, the result of which was invariably correct; in those days he could only be certain of this by the advent or the non-advent of the secondary symptoms, but at present we have the Wassermann's reaction to rely upon. So in those cases in which it would be an advantage to slit up the foreskin or to perform circumcision, but a negative Wassermann would negative any such operation. Many surgeons say that a negative Wassermann should not be always regarded as final, especially when the patient has undergone mercurial treatment, if only for a short time; however, the present case proves that a negative Wassermann may be perfectly correct, even under such circumstances.

SPECIAL REPORTS.

THE ANNUAL OPHTHALMIC CONGRESS AT OXFORD.

The annual Ophthalmological Congress was held at Oxford on Thursday and Friday, July 9th and roth, under the mastership of Mr. R. W. Doyley. It was attended by rather more than the usual number of members, and proved to be one of the most successful yet held. The addresses given in the mornings were extremely interesting, and led to some spirited discussions. On Thursday afternoon operations were demonstrated by several surgeons at the Eye Hospital, and some cases of interest were shown.

On Friday morning there was a discussion held on "The Question of Compensation in Injuries to the Eye." It was opened by Dr. William Robinson, of Sunderland, Dr. Frank Shufle-botham, of Newcastle-under-Lyme, speaking next, Messrs. Evans, Gray, Southall, Shiley, and Coull also spoke.

The annual dinner of the Congress was held in the Hall of Keble College on Thursday night, Professor Arthur Thomson being in the chair. After the dinner a discussion on the future of the Congress was held, when it was agreed to carry on the success of the meetings in the past, to continue to carry them on in the same way as before.

This year the addresses on the scientific and commercial museums were all held in the Department of Human Anatomy, kindly lent by Professor Arthur
Thomson, the fact of them all being under one roof being a great improvement on the previous arrangement.

Amongst the distinguished visitors to the Congress from America were Dr. Casey Hayes, Dr. Wendell Reder, Dr. Brown, and Dr. Gifford from the United States, and Dr. Darier from Paris.

The meeting, which terminated on Friday night with the usual singing concert, reflects great credit on the Master, and the energetic Secretary, Mr. Sydney Stephenson.

ROYAL COMMISSION ON VENEREAL DISEASES.

At the forty-sixth meeting of the Royal Commission, evidence was given by Dr. Svend Lomholt, Surgeon to the Municipal Hospital at Copenhagen, regarding the methods adopted for dealing with venereal diseases in Denmark. The principle has been to provide free treatment and to render it as easily accessible as possible, and in order to make this right of practical value an Act was passed in 1906 which contained a provision compelling the municipalities to arrange easy access for free consultation and treatment. Since that date, especially in Copenhagen, in which town probably 80 per cent. of the disease occurring in the country is to be found, a great deal has been done. Very complete hospital facilities have been provided, and in addition there are three public consulting rooms for contagious and venereal diseases at one of which evening consultations are held.

Twelve municipal doctors (two of whom are women) have also been appointed for the purpose of giving free treatment of venereal diseases. The experience has been that patients have shown themselves very ready to take advantage of the facilities. In some directions compulsory measures have been adopted. A doctor treating a case of venereal disease is required to point out all the consequences of the disease, and there is also provision for securing that persons suffering from the disease are not discharged until their disease has been properly treated. Dr. Lomholt thought that this latter provision had been very useful.

A system of confidential notification of venereal diseases is in force. The names and addresses of the patients are not notified, and the cases are identified only by numbers; the notification is consequently only of use for statistical purposes. Dr. Lomholt has made a critical examination of the published figures, and said that they could only be accepted with a good deal of reserve.

Mr. Charters Symonds, Consulting Surgeon at Guy's Hospital, giving evidence, laid stress on the need for largely increasing the means available for treating venereal diseases. He thought that burning inspections should be utilised as far as possible, and that these, together with any additional provision which might be made should be linked up with Insurance Committee areas and with panel doctors. Evening clinics should be provided at every centre. It would be necessary that a scheme of this kind should receive adequate subsidies from the State.

Mr. Symonds advocated the formation of a National Society which should supervise the selection of lecturers, the scope of teaching and the publication of books and pamphlets with a view to the education of the public respecting venereal disease. Such a society, he thought, should be voluntary and should be ready to be helped by the Government. A measure of which the Government approved. He would propose that the Royal Society of Medicine should nominate persons to serve as a committee of this National Society, which should have a definite sum of public money should be placed in the hands of that body.

With regard to the question of notification, Mr. Symonds said that the experience of other countries showed that in the present state of mind of the people notification was ineffective. It led to greater concealment of disease and tended to drive sufferers to quack treatment.

Mr. Arthur J. Evans, Honorary Surgeon to the Liverpool Stanley Hospital, was of opinion that if better facilities for treating venereal diseases could be provided at the general hospitals the spread of infection would be reduced. The establishment of such a clinic to a hospital should, he thought, be financed and controlled by the State and not by the committee representative of the charitable public. He thought that in poor-law patients the rate of the latter manifestations was very high. In the male sex this was exceedingly striking, and in a larger number of cases permanent incapability of earning a livelihood was produced; many also were beyond any hope of any form of treatment. Unfortunately a great difficulty in regard to Poor-law patients arose from the fact that there was no law to compel them to remain till properly cured. Patients frequently left the hospital while still in an infectious state.

As medical adviser to an important shipping company, Mr. Evans said that it was his experience that a great deal of venereal disease was introduced from abroad, and it was his opinion that this continuous introduction of disease into this country should undoubtedly be brought under control. He recommended that the Board of Trade should take steps to warn and explain to seamen and others the dangers of contracting venereal disease and that of infecting others of the community. The importation of disease would, he thought, be greatly lessened if sailors were aware of the risks encountered in foreign ports, and especially in the tropics.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, July 18th, 1914.

At the Hufelandische Gesellschaft, Mr. Petersohn discussed the

TREATMENT OF TUBERCULOUS BONE AND JOINT

DISEASES AND THEIR SEQUELAE.

He was altogether in favour of conservative treatment of such cases. Orthopaedic measures were supplemented by heliotherapeutics, which was easily carried out in that locality during the summer period. Tuberculous disease of bones was not suitable for treatment in city hospitals or cripples' homes, but in the open air. The more practical class of cases he recommended arbour colonies or arrangements of that sort, where sanubaths could be made use of. Treated in that way tuberculous fistula that had existed for years, could be cast off when spontoaneously and sealed up. Where the disease was only in one part and easily accessible, and the neighbouring joint not yet attacked, it should be radically removed. The speaker showed three cases of deep-seated joint disease in which he had strengthened the spine by transplantation of portions of tibia after the method of Albee. He was not yet, however, in a position to give a definite opinion as to the value of that form of treatment. He then showed two cases in which he had performed tuberculosis femoro-stomy for serious ankylosis of the femur after coxitis; the functional result had been remarkably successful.

At the Gesellschaft f. Geburtshilfe und Gynäkologie, Mr. Franz communicated a note on

CESEANEAN SECTION.

The speaker said he no longer practised extra-

terotional Cesarean section or symphysiotomy. He had had no satisfactory experience with the former, and the operation complicated matters very seriously. All that was wanted could be done with the intraperalonal method, but this should be made as simple as possible. In three years and a half he had operated in 120 cases. The technique had been similar in all of them. The incision, made longitudinally between the symphysis and umbilicus, was as small as possible. The uterus was also incised in the same direction, without any pushing down of the bladder. The head
AUSTRIA.

Vienna, July 18th, 1914.

Tenth Congress of the International Society Röntgen-Gesellschaft.—Continued.

III.—Therapeutic Application: Suprascapular and Deep.

Dr. Heinke (Leipzig) made a communication which dealt with the subject of "The Extra-Biological Effects of the Röntgen-rays.

1. The effects of the rays on living cells are very different according to the degree of sensibility present in those structures. For instance, in the case of lymphocytes, exposure to the rays produced immediate destruction of the nucleus, while the epithelial and embryonic gland cells displayed under the same conditions of exposure a slow modification of structure, which commenced after the lapse of a certain period of latency. (a) The period of latency was not yet being defined; it has been shown by Hertwig and Wassermann that the cells may proceed to division without actually dying. This process of sterilisation of the cells throws light on the period of latency, after the close of which a defect of tissue development, although not immediately due to the production of new cells. (b) The various modes of reaction of tumours display themselves according to the varieties of sensibility of the normal cells of the tissues from which they have been derived.

Dr. F. Heimann (Breslau): On "The Influence of various Filtering Media in the Mesothorium Radiation of the Ovary of the Rabbit." The author had employed a filter constructed of a thickness of 1 mm. of brass, 3 mm. of aluminium, and 3 mm. of lead. He had also applied the rays through a filter of 0.2 mm. of silver. It was only with the use of a lead filter that the destructive effect on the ovary was displayed, and the same feature was manifested in clinical research. In the case of cancer a rapid effect was produced on the epithelium.

Dr. Wolff (Berlin) communicated the results of his researches on bacteria, which had given purely negative results. He had also failed to obtain any therapeutic effects in the case of cancer.

Dr. Friedländer (Schöneberg) found the effects of radiation of the testicles of the guinea-pig as powerful with small doses as with large ones.

Dr. Evler (Berlin) saw cutaneous results in cases of suppuration, which could be traced through the progress of the infection and its cure.

Dr. Eberlein referred to the difference which he had noticed between the effects of radiation treatment of bothyromyositis in living animals and their wholly negative influence on the parasite in the test-tube.

Dr. Hasman (Berlin) stated that a more positive result was obtained when hard glass was used.

Dr. Eymer (Heidelberg) had also obtained appreciable effects in vitro.

Dr. Löwenthal (Brunswick): "On Radiation Therapy with the Use of Heavy Filters." Up to the present it had been impossible to produce results corresponding to the gamma-rays with the Röntgen tubes. The author had, however, succeeded in procuring, with the help of a 1 to 3 mm. lead filter, rays of that characteristic. After this he succeeded in showing that after exposure to the lead a portion of the rays were absorbed by the tissues of the body. Of the rays which passed through 1 mm. of zinc no less than 70 per cent. were afterwards absorbed in passing through the organism. By filtration through 1 mm. of lead a sufficiently powerful radiation was obtained which could be applied without injuring the skin. Behind the filter were found (1) primary ravs, (2) characteristic secondary rays, and (3) a special form of radiation similar in quality to the cathode-rays.

Dr. Pagenstecher (Brunswick): On "The Continued Treatment with Röntgen-rays." Comparatively little effect had hitherto been recorded of their use in the treatment of deep-seated tumours. Intensive radiaction had been tried in conjunction with various forms of exposure, so that only large doses were discussed. Then came the introduction of long pauses after the dangers of burns became recognised. But the tumour found time during these pauses inactivity of growth, and proceed to further expansion. In order to obviate such drawbacks, the author substituted, for the hard 3 mm. aluminium filter, either one of 1 to 1 mm. of lead or one of 2 mm. of copper. With these no injury to the skin had been observed, but after radiation of the same cutaneous area during a total period of 120 hours. In order to facilitate the application of those long periods of radiation—of one or two hours daily—Hrn. Pagenstecher and Löwenthal had prepared a filter-chest which was furnished with
dense filters through which the rays were allowed to reach from four to six persons at the same time. The author had also had a tube constructed which was furnished with an internal filter. In the intervals of the Röntgen-radiation small quantities of radium were utilised. Dr. Hessmann (Berlin) remarked that when using a brass filter of 1 mm, thickness, the exposure must be four times as long as with a 3 mm. aluminium one in order to provide a corresponding dose.

Dr. Hessmann then read a communication on: “The Röntgen-ray Treatment of Malignant Tumours with Massive Doses,” with special regard to the use of the Röntgen-rays in the radiation treatment of cases larger masses of radium—massive—doses, and had obtained favourable results in 10 per cent. of his cases. In cases of tumours of the larynx or pharynx he combined the Röntgen and radium rays. With the administration of massive doses a general toxic treatment must be adopted at the same time. Cases of tumours covered with the skin were treated with only 4 s., through a 3 mm. aluminium screen. Softer tumours which were already breaking down should be treated with canalisation. After the use of 4 s. he had seen necro-tension and removal. In treating tumours without any cutaneous investment he employed various filters. In the usual post-operative radiation therapy, special caution must be taken in most cases to use the greatest possible dose of Röntgen-rays as contrast with the procedure in surface therapy, an interval of six weeks must be allowed. In the percutaneous treatment of gastric carcinoma a 5 mm. aluminium filter should be employed. He recommended the preparation of gastric tumours by radiation treatment by preliminary surgical procedure.

Dr. Wichmann (Hamburg) discussed the “Value of the Röntgen-rays in the Radiation Treatment of Carcinoma.” The effectiveness of the Röntgen-rays in the treatment of carcinoma is hedged about with objections; surgical operation, mixed injection, infra-red, or relatively unfavourable relations or circumstances of the growth, and so on. The softer rays are suited to the treatment of some cases of carcinoma, the harder to others. An unfavourable result does not mean that the Röntgen-rays must necessarily be reformed with radium.

Dr. Paul Krause (Berlin): “The Röntgen-ray Treatment of Mammary Carcinoma.” On a basis of vast material, the author discussed the therapy of mammary carcinoma treated; the importance of preliminary operation, post-operative radiation, and radiation of recurrent growths. Exclusive radiation treatment gives a very unfavourable prognosis. Good results were attained only in cases of very small tumours and sparse patients, or in selected ones without considerable glandular metastasis. Recurrence with glandular metastases require a favourable field, with direct radiation; and perseverance on the part of the surgeon, with endurance on the part of the patient. In such cases shrivelling or connective-tissue degeneration was nearly always produced. In addition to the local radiation, prophylaxis of the thorax and cervical zone was necessary, so that when all diseased tissues had to be removed the operation should be submitted to the radiations and afterwards united. In other cases the radiation therapy was commenced ten days after the operation, and proceeded with in monthly stages for a year. He advocated large areas of exposure, four, rather than one, taken at the same time, and the only parts covered were the face, scalp, and abdomen. As the recurrence nearly always took place in the subcutaneous connective tissue, an unfiltered, very hard Röntgen-rays tube were used. The results were then very favourable; he had made eight successes in six cases.

Dr. Manfred Fränkel (Charlottenburg): “The Röntgen-ray Treatment of Pulmonary Tuberculosis.” He had obtained favourable results in sixty-four of eighty cases. The improvement was both general and local. Commencing increase of the fever was a favourable prognostic symptom. Tuberculous lung tissue is more sensitive to the rays than normal. Tuberculous glands react like the so-called inflammation of connective tissue, cicatrificial contraction, and consequent encapsulating of the pathological focus. Von Pirckaine become thick shells, and pleural thickenings and adhesions are broken down. He recommended the use of large doses of the rays in every case, and exposure of the whole thorax.

Dr. Eckstein (Berlin): “On some Unrecognised Effects of the Röntgen-rays, and their Therapeutic Value.” During the past five years he had obtained relief of pain, local shrinkage, and a change in the so-called Röntgen-rays—for example, after contusion. The relief was generally instantaneous, and continued for some hours, frequently for days, and occasionally for even months. He had combined the radium with 0.4—2 m. a., to a cutaneous area at a local distance of 15—30 cm., for a period of two to six weeks. He had also employed the Röntgen-rays for cases of skin ulcers, and for the so-called stasis of the cutis.

Dr. Fritze (Berlin): “The Use of Filtered Röntgen-rays in Chronic Eczema.” He had obtained favourable results in fifteen cases, by the use of aluminium filter. At each stage 1/8 E.D. was administered, till 2 E.D. had been reached; then a pause of three weeks was allowed.

(To be continued.)

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

PUBLIC HEALTH CONGRESS IN EDINBURGH.

At the Congress of the Royal Institute of Public Health, which was held in Edinburgh last week, the proceedings were of such varied interest, and covered so large a field of work, that it is impossible to do more than attempt, in a general way, to give some account of the principal communications. In the State Insurance Section, the President, Dr. Leslie Mackenzie, stated as the predominant problems in State medicine for the next ten years tuberculosis, housing, medical inspection and prenatal care of children, malarial epidemic, cancer, typhus, and the State medical school, and the organisation of research. In the subsequent proceedings of the section many of these were touched upon. Dr. Mearns Fraser, Portsmouth, in a paper on combating cancer, emphasised the fact that at present the only means of fighting the disease was to inform the public as to its nature, so that it might be removed early. Mr. Corbett Smith, introducing the discussion on sexual diseases, urged that education was the only solution; and that instruction must first be given to those who had to carry on the work of education. Frank speaking and avoidance of false modesty and hypocrisy were the first essentials.

TUBERCULOSIS.

In this section the discussion on tuberculosis centred chiefly round such factors as housing, and in a paper by Dr. Maxwell Williamson the great importance of dealing with slum property was emphasised. In the absence of such preventive measures as the checking of overcrowding, even a tuberculous environment could not produce much benefit. Dr. Alexander James was an exponent of the less orthodox view that tuberculosis was essentially a disease produced by the conditions under which people lived, and that Koch's bacillus was not a sufficient entity, rather the virulent transformation of a harmless, perhaps useful, organism, as the result of environment. In the pathological and bacteriological section, water-borne disease was one of the chief subjects discussed. In
CORRESPONDENCE.

The unavailing absence of the President, Professor James Ritchie, his opening address was read by Professor Beatie (Liverpool). In this address the occasional risk of water-borne typhoid was considered, and for estimations of coliform bacilli in water supplies was urged, but in estimating the meaning of the test it was necessary to consider the source of the water in relation to the possibility of contamination by any sewage. The examination of water was brought up by Professor Delépine (Manchester).

CHILD WELFARE.

The proceedings of the Child Welfare Section were opened by Dr. John Thomson's Presidential Address, in which the necessity for further legal powers for controlling the feeding of children and protection from the slumming of the criminal and pauper classes was insisted on. Dr. David Forsyth opened the discussion on the care of children under school age, in which he spoke of the pressing need of practical training of girls in their responsibilities as mothers. The babies whose mothers had to go out to work might be utilised in the practical training of girls by opening day nurseries near schools. Papers in connection with this subject were also read by Dr. Becket, Dr. A. K. Chalmers, Dr. Ballantyne, Dr. Mary Barclay, Miss Isobel Morris (of the "Duty and Discipline Movement"), and a number of others.

NATIONAL INSURANCE AND PUBLIC HEALTH.

In the second day's proceedings the topic of the State Medicine Section was occupied by the Address to the Council on National Insurance and Public Health administration, in which three by-products of the Act were specially mentioned—first, the accumulation of sickness records; second, the last report of the Nuffield Trust; and third, the achievements of the American, Australian, and Islands medical grant. Dr. Dunlop read a paper on the "expectation of life" judged from the mortality statistics of various Scottish towns. The range was very great; at birth the male expectation of life was 54.1 years in Kilmarnock and only 43.6 in Govan; at 25 it was 40.5 in Perth, against 38.9 in Govan.

THE MILK SUPPLY AND THE HOUSING PROBLEM.

again furnished matter for discussion in this Section. The most interesting and important papers, however, were those read on tuberculosis at the Tuberculosis Section and in the joint meeting of the Child Welfare and Pathological Sections. In the first of these the administrative aspects of the problem were emphasised, and the contributions of different countries and localities by Sir Robert Philip (President), Mr. Warburg and Dr. Halliday Sutherland (London), Dr. Bowditch (New York), Professor Haussen (Bergen) and Professor Rist (Paris), and many others. In the joint Section interest centred round the incidence of the disease in children and the milk supply. Professor v. Pirquet said that in Vienna infection through the lungs was the common source, and that in Austria and Germany cow's milk played no part. His conclusions, briefly, were: That for the first year of life respiratory was by far (95 per cent.) the most frequent; enterogenous infection (1-2 per cent.) was not important, and that prophylaxis had chiefly to do with this last. In Austria, in 1914, milk was invariably boiled before being used.

Professor Sims Woodhead's paper referred to the water supply, and those read on tuberculosis dealt with the danger to infants of the milk from tuberculous cattle. Dr. Haussen (Bergen), thought that infection from adults was the chief source of infection. Dr. Shennan emphasised the importance of continuously being forgotten—viz., that each locality must find out its own facts for itself. He would expect that in Edinburgh, where there was so much bovine infection of joints, there would also be a large proportion of bovine lung infections. These had not been proved experimentally. Dr. McNeil showed that the results of the von Pirquet test were quite different in Edinburgh from Vienna, the incidence of infection being much higher during the first four years of life, and lower during the later years of childhood. In Vienna the positive reactions during the first year are 5 per cent., whereas in Edinburgh they are 15 per cent., rising to 45 per cent. by the fourth year.

All the subsequent British speakers—Professor Delépine, Mr. Stiles, Dr. Mitchell, and Mr. Fraser, were strong in insisting on the real risks of milk infection and its country. In England the examination of milk showed that the small amount of surgical tuberculosis in Vienna was due to the milk being sterilised. Dr. Mitchell quoted 80 consecutive cases under 12 years of age in which 71 bovine and nine human infections were found. Of 406 samples of milk 82 contained tubercle bacilli.

IN THE INDUSTRIAL HYGIENE SECTION.

The Injuries of Soaps (Dr. F. Gardiner), "Dust and Tuberculosis" (Dr. Beattey), "The Electrifying Treatment of Lead Poisoning" (Mr. Chalmers), "The Campaign against Mosquitoes" (Surgeon D. H. Given), and other subjects, were discussed.

In addition to the sectional meetings, an exhibition of apparatus was also arranged, which was connected with child welfare campaigns from which various demonstrations on the diseases of children, nursing, massage, hygiene, etc., were given.

The exhibition was largely taken advantage of not only by members of the nursing profession, health visitors, and parents of all ranks.

After the first day's proceedings the members were entertained at a reception by the Lord Provost in the Royal Scottish Museum; on the next evening the Congress Dinner was held, and on the following day the College of Physicians gave a dinner to some of the members. A number of garden parties and excursions were also arranged, including a garden party at Hope-von House by the Marquis of Llindthig.

In reference to the resolution recently come to by the Ayr Burgh Insurance Committee to bring home, owing to lack of funds, their phthisis patients presently being treated in sanatoria, it appears that these patients are far in number. A matter afterwards came under the notice of the Ayr Town Council, who entered into communication with the Local Government Board and obtained an interview with them. The Town Clerk subsequently received a letter from the Board in which they stated that with child welfare arrangements, at any rate from want of funds or any other reason discontinued the treatment of insured persons, it fell to the local authority to attempt these cases if further treatment was necessary, and that it rested with the local authority to determine that the patients in question were in doing so they ought to be guided by the medical officer of health. In the view of the Board it was advisable that the nine patients in question should not be removed until it had been determined what further treatment was to be given to them.

NEW PROFESSOR OF CHEMISTRY AT ABERDEEN.

Mr. Frederick Soddy, M.A., F.R.S., Lecturer on Physical Chemistry in Glasgow University, has been appointed to the Chair of Chemistry in Aberdeen University, formerly held by Professor Japp. Mr. Soddy, who is 36 years of age, has already had a brilliant career. While Demonstrator in the Chemical Laboratory at McGill University, Montreal, from 1900 to 1903, he obtained a considerable experience in the physical investigation of radio-active phenomena, for the most part in conjunction with Professor Rutherford, to whom he owes his initiation in this subject. The result of this joint work was a paper giving the interpretation of radio-activity by the theory that the atoms of the radio elements are undergoing spontaneous disintegration. In 1903 he continued the work with Sir William Ramsay in London. They isolated the radium emanation in a pure state, and spectroscopically obtained the generation of it from the element helium. During this time Mr. Soddy lectured on radio-activity in the University College, London, and the Cavendish Laboratory, and in 1904 he gave a course of University extension lectures in Western Australia on modern advances in the physical sciences.

UNSUCCESSFUL ACTION FOR DAMAGES.

The case in which a lady patient sued Dr. A.
Lamont, Esslemont, Chryston, Lanarkshire, for £500 damages, was tried in the Court of Session last week before Lord Anderson and a jury. The pursuer had cut her left little finger when pruning in the garden, and was treated by the defender. In consequence of alleged fault of the pursuer before the doctor's part in his treatment, the pursuer had afterwards to get her finger amputated. The defender denied that he had been guilty of fault or negligence. The jury, after an observation of an hour and three-quarters, returned a verdict for the defender.

NEW LECTURESHIP AT ABERDEEN.

Mr. John Parlane Kinloch, M.D., D.P.H., has been appointed to the new Lecturehip on Public Health in Aberdeen University, out of six applicants. He is 28 years of age, and graduated M.D. at Glasgow University with commendation, having previously qualified there in 190; and he took the diploma in Public Health at Cambridge, with distinction in sanitary science. Dr. Kinloch has considerable teaching experience in Ruchill Fever Hospital, Glasgow, and as Assistant Lecturer on Public Health in the Anderson College of Medicine, Glasgow. His research work has included investigations of the biological properties of the typhoid, the diphtheria, and Cerebrococcus, and the origin of return cases of scarlet fever.

MEDICAL SERVICE IN COWAL.

Dr. McIntyre, Inselan, and Dr. Edgar, Lochgoilhead, were among those who attended a conference at Dunoon between the Highlands and Islands Medical Service Board and the representatives of parishes in the district. Small hospitals throughout the district were present, but the influential landowners present favoured the alternative of a powerful motor ambulance in connection with Dunoon Combination Hospital, which can take more patients.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

"THE BRITISH PHARMACOPEIA—1914."

To the Editor of THE MEDICAL PRESS and CIRCULAR.

DEAR SIR,—At its meeting to-day the Executive Committee of the General Medical Council formally adopted as "The British Pharmacopoeia, 1914," the complete draft submitted by the Pharmacopoeia Committee. It was resolved that copies, in advance of publication, should be made accessible to the public for inspection in the offices of the Council in London, Edinburgh, and Dublin on Monday, August 10th, at 10 a.m., and thereafter from 10 a.m. to 4 p.m., and that a copy for review should on the same day be placed in the hands of the editor of each of the medical and pharmaceutical journals on the Registrar's list.

The official publication of the new "British Pharmacopoeia" will be made by notice in the Gazette on Friday, October 1th, on which day copies will be on sale at Messrs. Constable and Co., Ltd., 10, Orange Street, Leicester Square, W.C. I am, Sir, yours truly,

NORMAN C. KING, Registrar.

THE DECAY OF FRANCE.

To the Editor of THE MEDICAL PRESS and CIRCULAR.

SIR,—The crude details of politics, the mere play of parties, seem to lie far outside the scope of medical journalism, but when physiological factors make up great part of the complex system of causation whereby the destinies of nations are moulded, the subject becomes of absorbing interest to the whole scientific world and the journals that represent it. If there are at present any peoples showing signs of decay, it behoves the nations around to inquire into the phenomena, and to avoid the diseases of the body politic that appear to threaten or already seriously affect their neighbours. With regard to our fast friends, the French, the policy of international pin-pricks has long given way to the extende; the virulent hatred during the Boer War and the episode of Fashoda have been quite forgotten, and the two nations of France and British are now working together with united and friendly intentions, rather than with an eye to the future." This month the French medical weekly has published the following article:—"The two medical applicants. If a newspaper publishes startling statements by its French correspondents, it never comments upon them in its editorial columns, nor does it allude to the solid fact that we have advanced far along the road of international friendship and commerce with our French neighbours. A most remarkable illustration of the indifference of the British Press was manifested during the Paris Hygienic Congress in May, 1913. The question was there once more discussed from the standpoint of the two distinguished churches by two Frenchmen, M. Leprince and M. Leclerc Bourgeois, who dwelt upon the danger from foreign attack due to the comparative paucity of their population and the continuously progressive decline in the birth-rate. He pointed out that the British population contains 15 per cent of the population of Europe, whilst to-day she has only a per cent. The excess of births over deaths during the period 1906 to 1910 was lowered in France by 50 per cent, whilst it remained practically stationary in the French and neighbouring countries. In 1911 the deaths exceeded the births by 43,850, while the number of births was the lowest ever recorded. M. Ribot, after adopting and emphasising all his country's statements and dwelling upon the fact that the French population has lost two fifths since 1871 and has long been much higher than that of their Northern neighbours, ended his speech with the following words:—"This country is sick, and it ought to be proclaimed aloud. The French race is withering. The people must be informed of the peril by which it is menaced. All the efforts of the Legislature and of the Government must be concentrated upon grasping with this peril." This profoundly impressive confession and appeal was entirely ignored by our home journals, and this is in marked contrast to the fate of similar reports of an equally alarming kind. The Times of June 26th last contained a telegram from its Paris correspondent on the still alarming decline in the birth-rate. The number of births last year was 745,460, the lowest ever, while the lowest figure ever shown with the exception of 1811. In less than 40 years the birth-rate has diminished by 280,000 a year. The statistics become more and more disquieting, when compared with the returns of other countries. Germany has at least 30,000,000 more people than France. If, like France, she should impose, instead of two years, a three years military service, she might make it virtually impossible for France to defend herself even with the help of her allies. It is now seriously proposed to displace the 1,000,000 of foreign European settlers in France by labour from the Kabyle and other tribes in the French African colonies. It is also seriously proposed to augment the army in France from similar sources. These ideas
are set out at length in a dispatch from the Times correspondent in its issue of Monday last, July 13th. The former idea is perhaps practicable; it is at least extremely significant. The second suggestion is even more significant, albeit grotesquely absurd, in view of the fact that establishment. The uniform subjects of abtropical and tropical Africa would die literally like flies in a European winter campaign. France is surely presenting us with an object lesson to which we cannot afford to shut our eyes. Our imperial responsibilities depending for their enforcement on the strength of our people, are inculcably vaster than hers. It is a big subject. In my letters so far I have barely opened it, and although ready to go on, I am equally ready to stop at the smallest hint from you.

I am, Sir, yours sincerely,

HENRY SEWILL.

The Old Rosery, Earlswood Common, July 17th, 1914.

OBITUARY.

SIR CHRISTOPHER NIXON.

It is with deep regret that we have to record the death of Sir Christopher John Dixon, Bart., which took place on Sunday last at his residence, in Dublin. The deceased gentleman, who was born on January 19th, 1845, the son of Mr. C. W. Nixon and Mary Anna, daughter of Mr. W. J. Hackett. He was educated at Trinity College, Dublin, the Cecilia Street School of Medicine, and at Paris. He qualified as L.R.C.S., F.R.C.P. in 1867, and D.M. in 1878. He was appointed F.R.C.P.I. in 1876, and received the M.D., R.U.I. (honoris causa) in 1885. Sir Christopher Nixon was well known to the medical profession in Ireland, having occupied the position of President of the Royal College of Physicians of Ireland, as well as having been Vice-Chancellor, a member of the Senate, and a representative on the General Medical Council of the National University of Ireland. Senior Physician at the Mater Misericordia Hospital, a Fellow (late President of the Pathological Section) of the Royal Academy of Medicine of Ireland, Professor of the Practice of Medicine in the Catholic University, etc...

A communication to the Times contributes the following appreciation of Sir Christopher Nixon:—"Ever keen and sympathetic as a practitioner, his remarkable powers of diagnosis in seeing through and through a patient's ailments almost at a glance, and his exceptional ability and skill, he rapidly won his way to the foremost place amongst the men of his time, and after holding many important positions in Ireland was made a Privy Councillor amongst the New Honours of this year. As a member of the General Medical Council he came to London regularly to attend its meetings, and was well known in Liberal circles of London society. A man of many parts, energy and ability, he was regarded by his pupils and intimate friends—not all of them of his own generation—as gifted with a geniality which has given to practice to humanity what might have been intended for the library and lecture-room of the Academy."

REVIEW OF BOOKS.

FIRST HINTS IN DENTISTRY. (a)

This "causerie" on a subject of which the importance seems to advance daily with seven-league-boots stride in this our "decadent generation," is well intended, as we are told in the preface, to the benefit of friends in general: "leur exposercar qu'il faut faire et ne pas faire." The author skilfully advocates and logically defends his application of the term Stomatologie to the theory and practice of his specialty and he unquestionably shows his readers what to do and what not to do with the enviable lucidity and coincident impressiveness of thought and diction which so uniformly characterise the published expositions of the Gallic experts in science and philosophy.

The first chapter of this book is the most appropriate heading which embodies the statement that: "When the teeth become painful, then, indeed, is the time to seek advice." And from this very judicious beginning down to the closing of his terminal (final) chapter, our author's text is quite egg-full of the most lucid information and suggestion, conveyed in an exquisitely luminous style, which will surely enable every Frenchman in the street to read as he runs, at bow-wow speed. The dictionary selection of subject matter are, of course, meant to be of the "popular" quality, but we have no hesitation in expressing the opinion that no general practitioner of the art of healing, or student of the prevention of disease can fail to find in the teachings of the author, the highly instructive and highly entertaining contents of this book most readable and suggestive little volume.

SMALL-POX AND SANITATION. (b)

When we noticed Dr. Hanaa's book in these columns some months ago, we anticipated that the facts contained therein would prove a valuable and important factor in the anti-vaccination movement, and the event quite justifies our anticipation. Our readers will remember that, stated in the most general terms, Dr. Hanaa's investigations went to show that among vaccinators the immunity between the age of forty and twenty years there were no deaths from small-pox. After this the percentage case mortality rose during the next two decades, to fall again during the ages between fifty and sixty years, while from sixty years and upwards it just reached ten per cent. Among unvaccinated persons the percentage case mortality for those under two years of age was 85 per cent. between two and five years 36.6 per cent., between five and ten years 19 per cent., between ten and fifteen years 3.2 per cent. After this age period the percentage case mortality again rose till between the ages of forty and fifty years it reached 50 per cent., at which figure it remained constant for the remaining periods. The figures also tended to support the belief that the protection afforded by vaccination here some relation to the scar area left by vaccination. We have not space to state in detail the reply of the Anti-Vaccination League to these figures, but we shall indicate the lines on which the reply proceeds. It is urged that the belief observed the protecting power is most, like the greater decline in the incidence of typhus

(b) "Studies in Small-Pox and Sanitation, based on the experience of the Liverpool General Hospital, entitled "Studies in Small-Pox and Vaccination" by William Hanaa, M.D. Published by the Anti-Vaccination League. London: 1914.
fever, be due to the cause operating in common in both diseases—improved sanitation. In this connection we would point out that there is no antagonism between vaccination and sanitation, and no one denies the influence of improved conditions of life, and of the sanitation of small-pox. One must beware, however, of the fallacy of comparing the general mortality from one disease with the case mortality from another. What Dr. Hanna's figures seem to show is that the case mortality of small-pox, expressed in terms of the age period for the vaccinated than for the unvaccinated in the same town, and for the vaccinated, for all age periods, was 2.9 per cent., as compared with 22.7 per cent. for the unvaccinated. It is no fairer to draw the conclusion that this percentage of 27.7 is much higher than it is in other places, such as Leicester. So far from being shattered, Dr. Hanna's argument is not touched by the fact that it was safer to hope for the recovery of liability to death to be attacked in badly-vaccinated Leicester than in well-vaccinated Liverpool.

We have said enough to show the general trend of the reply, a careful study of which we would recommend to our readers, not because we think it will upset the original statement of Dr. Hanna, but because we think that a recognition of the fallacies that it contains will confirm one in the belief of the uselessness of vaccination as a measure of preventive medicine.

ST. BARTHOLOMEW'S HOSPITAL REPORTS. (a)

The current volume of the 'St. Bartholomew's Hospital Reports' well maintains the high traditions of that ancient institution, and sets an example to other similar institutions of much good work well done and carefully handled. Besides interesting memoirs of the late Mr. Alfred Willett and Mr. Raymond Broadley Etherington-Smith, the volume contains two medical and five surgical papers. Dr. Sladden gives an interesting account of a trial of some tests in paralytic chorioretinitis; Dr. Alton and Dr. Broadley gives a case of blood in myelocytic leukaemia in relation to the prognosis of the disease. Dr. Thurnfield writes on splenectomy in acholeucytic jaundice, and Mr. D'Arcy Power on appendicectomy in the treatment of ulcerative colitis. Mr. Moreton records an interesting case of post-orbital arterio-venous aneurysm successfully treated by ligation of the internal carotid artery. Mr. G. W. Twigg writes on pes cavus as an initial sign of syphilis and Mr. H. J. Bergold gives an interesting account of the experience of the use of neo-salvarsan in the Skin Department of the Hospital. The usual statistical tables and information concerning the hospital work complete the volume.

ULCER OF THE STOMACH. (b)

For almost one hundred years since Matthew Baillie and Crueviller first thoroughly investigated the subject of ulcer of the stomach and established the disease as a definite entity in our nosology, the subject has been one of fascinating interest to generations of medical workers. In spite of this, we are still sadly deficient in exact knowledge as to the causation of the condition, and this deficiency, no doubt, largely accounts for our failures in its treatment. When moreover in an attempt to achieve success in intra-abdominal operations it seemed as if the treatment of gastric ulcer were about to pass from the domain of the physician to that of the surgeon, and patients with the symptoms of ulcer of the stomach flocked to the surgeons to be cured by operation of their distressing complaint. Operations undertaken under these conditions soon revealed the fact that our diagnoses, of which we used to be so certain, was often erroneous, and even when treatment was not infrequently failed to give any permanent relief. These discoveries have led to a profound modification of our ideas and the whole subject of gastric ulcer, its diagnosis, its causation, and its treatment, has been again cast into the melting pot for further study. What the outcome of this further study will be it is impossible to say yet to those who believe that it will lead to great increase in our knowledge and in our capacity for assisting the unfortunate sufferers.

Dr. Bolton has taken this opportunity of stating for us the problem of the disease, and the side of the question's which Mr. Broadley's book deals with. In its conclusions, Mr. Broadley's volume, is the opinion held at the present time that the disease is caused by a specific organism, which is a bacillus that can be cured by iodide of potassium and those that could not. The diagnosis then was simple and had the advantage of depending on the result of treatment instead of being the foundation of that result. We have come to the conclusion that the disease is an independent entity that stage, and accurate diagnosis not infrequently leads to successful treatment. Accurate diagnosis is urgently demanded both by the physician and the surgeon, yet the difficulties in the way of achieving it are often thrust into the best endeavours. Dr. Bing has made this difficult path somewhat easier, and we cordially thank him for the help he has given. Our thanks, too, must be extended to Dr. Arnold for putting Dr. Bing's work within the easy reach of English readers.

ELEMENTARY ZOOLOGY. (c)

In this work the author has assumed that the student possesses an elementary knowledge of chemistry and physics. One general principle, he tells us, has guided him in its compilation—namely, that "the organism should be regarded as a whole." In further illustration of this principle he states in the preface: "I have not adopted views which are based on certain morphological institutions of the body of an organism, such as cells and zoids, a mystical individuality, based upon assumptions with regard to their history or potential independence. I have taken in this view the 'individuality or indivisibility of the organism.'" This statement rather conveys the impression of placing a severe strain upon the "mentality" of the average intending student of zoology. To such, perhaps, it might even prove alarming. But with the preface the student need not necessarily concern himself, and he will find in the author's pages one of the best expositions of the science of elementary zoology now extant for the student's use. The bulk of the work is naturally devoted to the study of the external and internal structures of adult animals. There is, however, an excellent chapter on embryology, constituting a most helpful introduction to the subject. For the most part students experience difficulty in grasping and remembering embryological facts, but in this chapter their pathway of instruction is smoothed for them as far as it is possible to do so.

Other chapters deal with "Classification and Evolution?" and "The Animal in the World," each of which adds immeasurably to the usefulness of the work.

In an appendix the necessary details are given concerned in the practical working of zoology, which we

would suggest would have been better placed as a special chapter at the beginning of the book. The first thing a worker has to learn is the tools and appliances required for his work. A word in commendation should be added in respect to the lavish number of illustrations explanatory of this as well as other parts of the work. We have recommended this manual as a trustworthy and comprehensive guide for the examinational purposes of the zoo student.

INDEX-CATALOGUE OF THE U.S. LIBRARY, SURGEON-GENERAL'S OFFICE. (a)

This, the latest volume to hand of this immense index-catalogue, comprises 1,057 double-columned folio pages, and includes titles under the initial letter T. This number alone occupied 522 pages, and the letter T occupied 82 pages. At that time the Surgeon-General's library contained 6,426 volumes and 8,580 pamphlets, and indexed 38,492 titles of articles in periodicals. To-day the library contains 132,641 volumes and 230,341 pamphlets. Book titles now number 295,049, and journal titles 1,089,778. Close on 1,720 columns are occupied with the titles of articles on Tuberculosis alone; in the 1893, 1894, and 1895 numbers was disposed of in 1,068 the science of chemistry is based. The price seems to us, however, to be somewhat prohibitive.

TREATMENT OF TUBERCULOSIS. (b)

This is a compact volume, of a useful size, dealing with the treatment of tuberculosis in all its forms. It commences with a general consideration of tuberculosis and the parts it affects, and then goes on to organize the International system of Ophthalmology. The treatment of predisposition and of actual phthisis, followed by the hygiene, treatment and alimentation which are of such vital importance in this condition. The pages devoted to the treatment of pulmonary phthisis are more than sufficient. The latest information is given and is complete without in any sense being drawn out, and should be read by every medical man whose work in any way brings him in contact with pulmonary tuberculosis. As part of our tuberculosis officers. The style of the book is excellent and the translator's part has been well done, whilst that of the publisher is beyond reproach, the type being easily read and exceptionally clear. The book is in cordially recommended for treatment of tuberculosis according to age and to the associated morbid conditions is very adequately dealt with, as also are those of extra-pulmonary tuberculosis affections: and the chapter on the social defence against tuberculosis is admirably done. The treatment of tuberculosis according to age and to the associated morbid conditions is very adequately dealt with, as also are those of extra-pulmonary tuberculosis affections: and the chapter on the social defence against tuberculosis is admirably done. The treatment of tuberculosis according to age and to the associated morbid conditions is very adequately dealt with, as also are those of extra-pulmonary tuberculosis affections; and the chapter on the social defence against tuberculosis is admirably done.

OPHTHALMIC SEMIOLOGY AND DIAGNOSIS. (c)

This book has been produced upon somewhat novel lines. It fills a space which has hitherto been vacant in the literature of the subject. Whether, however, that space having been filled the work will supply a need, remains to be seen. Nevertheless, it is worthy of study. The author has plainly devoted much time and thought to his work, and the book contains a mass of useful information for the ophthalmic student in a convenient and handy form. Again, a distinct and praiseworthy feature of the work is its emphasis upon the importance of observations, and some coloured plates of the fundus: these latter, the author tells us in his preface, form part of the collection of drawings which he has been making since 1884, all of which have been directly painted from the living subject. As the work consists solely of the symptomatology and diagnosis of diseases of the eye, and excludes the subject of treatment, it may be inferred that its accomplish- ment will be mostly fulfilled as a work of reference. There are some glaring misprints, showing careless proof-reading, and here and there is displayed a looseness of style, suggestive of hurried composition.

THEORETICAL CHEMISTRY. (d)

This volume serves as an introduction to the study of physical chemistry. The author has succeeded admirably in presenting such difficult problems as the quantitative theory of solutions and the principles of electro-chemistry in a clear and simple manner. The solution of numerical examples forms a definite part of the book. The volume consists of nineteen chapters, and is provided with a very complete index. In these chapters the theories of chemical science are very fully and clearly expounded, and we feel sure that a study of Dr. Getman's interesting work will greatly aid the student in understanding the fundamental principles of chemical science.

THE HEART BEAT. (e)

The rapid advance that has been made in recent years in the clinical investigation of morbid hearts has, we fear, tended rather to mystify than to enlighten many busy practitioners. The methods themselves require patient study and long-continued practice before they can be made to give satisfaction. These results, too, when obtained, though they have added greatly to our knowledge of the mechanism of the heart both in health and disease, have not as yet led to any profound consideration of the diagnosis or treatment of cardiac diseases. Under such circumstances it is not to be wondered at that the general practitioner is inclined to look on the methods of cardiography rather as a fad of the specialist than as an important and helpful aid to the clinical physician. While there is much that is sound in this position, it is quite obvious that the results of cardiography are of too much importance to be altogether neglected by any physician who wishes to do the best for his patients. In this admirable and concise little handbook, which gives in clear and concise language the chief facts and conclusions derived from the new knowledge, and lays stress on those that are of service at the bedside. The rapid evolution of a new department of clinical work (a) "Index-Catalogue of the Library of the Surgeon- General's Office, United States Army, Authors and Subjects." Second Edition. Revised and Corrected. Washington, 1913.

(b) "Treatment of Tuberculosis." By Professor Albert Robin. Translated by Dr. Leon Blanc. Assisted by Mr. H. de Mere. M.R.C.S., M.B.C.S. London: J. and A. Churchill.

(c) "Ophthalmic Semiology and Diagnosis." By Charles H. Beard, M.D. With thirty coloured plates and seventeen figures in the text. London: Kehmann, Ltd. 1913.

vidals the sequel of taking sulphates of the alkali metals. Besides its gentle purgative action, the sodium phosphate effects diuresis and adds to the acceptability of the preparation in cases with gout or rheumatism.

MEDICAL NEWS AND PASS LISTS.

The British Medical Association.

The eighty-second annual meeting of the British Medical Association will be held at Aberdeen on July 28th, 29th, 30th and 31st next, under the presidency of Sir John Loudon, K.C.M.G., M.D., F.R.C.P., Consulting Surgeon, Aberdeen Royal Infirmary and Surgeon-in-Ordinary to H.M. the King in Scotland.

Sixteen scientific sections have been arranged and will meet daily from Wednesday to Friday in the Marischal College. On Monday, Dr. Ogston, Surgeon-in-Ordinary of the Royal Infirmary of Aberdeen, conferred the Presidential Address on "The Anatomy in Physiology; Dermatology and Syphilis: Diseases of Children, including Orthopedics; Electro-Therapeutics and Radiology; Gynaecology and Obstetrics; Laryngology, Rhinology and Otology; Medical Sociology; Medicine; Naval and Military Medicine and Surgery; Neurology and Psychological Medicine; Ophthalmology; Pathology and Bacteriology; Pharmacology, Therapeutics and Dietetics; State Medicine and Medical Jurisprudence; Surgery; Tropical Medicine. The programmes throughout promise the most particularly interesting discussions owing to the large attendance of men of eminence from foreign countries and the Overseas Dominions.

On Tuesday, July 28th, at two o'clock in the afternoon, Sir Alexander Ogston will be inducted to the Presidential chair, while at 8.30 p.m. he will deliver his address in the Music Hall, Union Street.

On Wednesday, July 29th, at 12.30 p.m., Dr. Archibald Edward Garrod, F.R.C.P., F.R.S., will deliver the address on Medicine.

On Thursday, July 30th, at 12.30 p.m., Sir John Bland-Sutton, F.R.C.S., will deliver the Address on Surgery.

On Friday, the popular Lecture will be delivered by Professor J. Arthur Thomson, M.A., LL.D.

The last three addresses will be delivered in the Marischal College. A number of excursions have been arranged to places of interest in the neighbourhood.

Society for Relief of Widows and Orphans of Medical Men.

At the recent Quarterly Court of the Directors of this Society nine gentlemen were elected members of the first class, and 4,000 were voted for the payment of the half-yearly grants to the widows and orphans. At the present time there are 45 widows and 13 orphans in receipt of grants. The invalid funds of the Society now amount to £130,000. Membership is open to any registered medical practitioner who, at the time of his election, is resident within a 20-mile radius of Charing Cross. The annual subscription is two guineas, special terms for life membership, which vary with the age of the member. Relief is only granted to the widows and orphans of deceased members. Since the last Court five letters had been received from widows of medical men asking for relief. It had to be refused as their husbands had not been members of the society. Further particulars and application forms for membership may be obtained from the Secretary at the offices of the Society, 11 Chandos Street, Cavendish Square, London, W.

Deputation on Forcible Feeding to the Home Secretary.

The following statement has been sent to us on behalf of the intended deputation —

Today, at 4 p.m., a deputation of medical men was waited on by Mr. McKenna by appointment to discuss the matter of forcible feeding of prisoners. The deputation consisted of Dr. McIntosh (chairman), Dr. Haden Guest, Sir Victor Horsley, Mr. C. Mansell Moulin, Mr. Frank Moxon, and Dr. H. Schultz, thus representing the medical profession.

When the deputation was introduced they asked that reporters should be admitted. Mr. McKenna refused, on the ground that names of prisoners might be men-
toned in the discussion. The deputation then retired and discussed the Home Secretary's objection. On returning, they pointed out to the Home Secretary that his objection was without any weight, and that the names of cases to which they intended to refer had already appeared with details in the public Press. Mr. McKenna still refused to admit reporters, and in answer to Dr. McIntosh further refused even to admit the deputation's own reporter. Mr. McKenna said he had arranged that an official reporter should be present in order that the (Home Secretary) should keep full control over any report that ought to be sent for publication. The deputation then explained to Mr. McKenna that they could not accept his refusal, that their position in this matter of forcible feeding was under their public responsibility, and that therefore they demanded they should be heard in public. Of course the deputation is ready at any time to place its views before the Home Secretary should he reconsider his refusal.

Sanatorium for Woman in Surrey.

It is announced that the Metropolitan Asylums Board have purchased 27 acres of land at Hyde Hill, two miles from Godalming, for the purpose of erecting a tuberculosis sanatorium for women. Accommodation is to be provided for 200 patients. The land lies near the Thames, and is in the heart of some of the finest Surrey scenery. The plans for the building are in course of preparation.

Another Anonymous Gift to Cardiff.

It is announced that a further gift of £10,000 has been made to Cardiff Medical School by the anonymous donor who has previously made donations equivalent to £90,000.

A New Hospital for Hastings.

The Duke of Richmond and Gordon, one of the Provincial Grand Masters, laid the foundation-stone of the new hospital at Hastings last week, with full Masonic ceremonies. The building is to cost £50,000, and is to be erected as a memorial to King Edward.

London Hospital Scholarships.

The following awards are announced at the London Hospital Medical School —

Price Entrance Scholarships, Science, £100, C. S. Cloake; Anatomy and Physiology, £22 10s., L. G. Jacob; Entrance Scholarship in Science, £50, A. D. Adler.

University of London.

At a meeting of the Senate held on July 12th, it was resolved, in response to a request from the Board of Control, to suggest the following conditions for the grants allotted to the Board by the Treasury for encouraging scientific research into the causes and treatment of mental diseases and mental defect:—(1) Individual grants to be made to a few observers who have been thoroughly trained and who are capable of carrying out scientific investigation; (2) no grant under the scheme to be made merely to maintain or assist pathological laboratories or to be given to persons for the purpose of routine work; (3) grants to be given only to advance the study of fundamental problems connected with insanity and mental deficiency; and to inform the Board that the Senate would be pleased to advise them as to the objects towards which investigations thus aided might with most advantage be directed.

University of Cambridge.

At a Congregation held on July 15th the following degrees were conferred:—

M.C. — W. S. Perrin, Caius.

M.B. and B.C.—P. Stocks, King's; H. P. Dawson, Trinity;

S. G. Askey, St. John's; T. L. Hardy, Selwyn.

M.B.—F. E. W. Rogers (by proxy), Emmanuel.

B.C.—H. Hartridge, King's; W. B. Gordon, Clare;
MEDICAL NEWS AND PASS LISTS.

W. F. R. Smith, Pembroke; J. W. Pigeon, Christ's; C. Mackenzie, Emmanuel; C. R. A. Thacker, Downing.

Royal Colleges of Physicians and Surgeons of Edinburgh and Royal Faculty of Physicians and Surgeons of Glasgow.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on the 17th inst., with the following results:

First Examination.—The following candidates passed: Andrew J. Meck, Leslie Macduff, James Chambers, Percival C. H. Uomer, William V. Jackson, Blizard, L. Smith, Daniel St. Clair, Donald Vania and Edward L. Adendorff; and six passed in physiology, nine in biology, and four in chemistry.

Second Examination.—The following passed: John Black, William A. Mein, Frederick C. J. Mitchell, James H. Brown, David S. Byrne and Martha H. Houching; and two passed in anatomy and two in physiology.

Final Examination.—The following candidates, having passed the Final Examination, were admitted L.R.C.P. and L.R.C.P. and S.C.:

Joseph K. Venables, Kenneth G. Fraser, Thomas E. Lawson, David C. Graham, Robert M. Paterson, Reginald E. Illingworth, John M. Chrystie, Edward Blackburn, James A. Bannerman, and William Millicott, Jan M. Beyers, Walter Chapman, Frederick S. Bunting and Joseph V. Duffy; and five passed in medicine, three in surgery, three in midwifery, and 13 in medical jurisprudence.

Edinburgh University—Graduation Ceremonial.

On Thursday last, July 16th, the Principal Sir William Turner, Vice-Chancellor of the University of Edinburgh, conferred degrees on successful students as follows—Doctor of Medicine, 28; Bachelor of Medicine and Bachelor of Surgery, 155; Bachelor of Tropical Medicine were also awarded. The following is a list of the honours conferred, the names being given in alphabetical order.

** Indicate that the candidate has passed the examinations with first-class honours. *Indicates that the candidate has passed the examinations with second-class honours.

Edinburgh University—A Award of Fellowships, Scholarships, Prizes, &c.

At the annual graduation ceremony on Thursday last, the following were awarded:

The Cameron Prize in Practical Therapeutics.—To Professor Paul Erlich, Director of the Royal Institution for Practical Therapeutics, Frankfurt, for his discovery of salvarsan, and its valuable therapeutic effects in syphilis, and also for his researches on numerous synthetic organic compounds of arsenic and on immunity.

The Gunnion Victoria Jubilee Prize in Forensic Medicine.—Sydney A. Smith, M.D.

The Entles Scholarship.—Ralph C. L. Bachelor, M.A., M.B., Ch.B.

The Allan Fellowship in Clinical Medicine and Clinical Surgery.—Douglas J. Glen, M.B., Ch.B.

The McEoch Graduate's and Medical Bursaries.—Robert G. Bannister, M.B., Ch.B.

The Beaney Prize in Anatomy and Surgery.—Peter MacCallum, M.A., M.Sc., M.B., Ch.B.

The Monat Scholarship in the Practice of Physic.—Ralph C. L. Batchelor, M.A., M.B., Ch.B.

The Conan Doyle Prize.—Charles P. M. Jonsbert, M.B., Ch.B.

The Annandale Gold Medal in Clinical Surgery.—Ivan Keith-Falconer McLeod, M.B., Ch.B.

The Buchanan Scholarship in Gynaecology.—Peter MacCallum, M.A., M.Sc., M.B., Ch.B.

The James Scott Scholarship in Midwifery.—Andreas B. Theron, M.B., Ch.B.

The Dorothy Giffilhan Memorial Prize.—Gertrude M. A. Herzfeld, M.B., Ch.B.

The Wellcome Memorial Scholarship in History of Medicine.—Gold medal—Joseph Schneider; silver medal—William Everett.

The Wightman Scholarship in Medicine.—Robert G. Bannerman, M.A., M.B., Ch.B.

The Cunningham Memorial Medal in Anatomy.—Robert Walker.

The Whiteside Bruce Bursary.—Henry J. Parish.

Conjoint Examinations in Ireland.

The following candidates have passed the second professional examination by the Royal Colleges of Physicians and the Royal College of Surgeons, July 1914—

NOTICES TO CORRESPONDENTS &c.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. To reduce postage charges on our monthly issues, foreign subscriptions must be paid in advance. For India, Malay States, New Zealand, and Colonies, we are officially-appointed agents. Indian subscriptions are Rs. 15-12-0. Messrs. Daws and Sons are our special agents for Canada. For South Africa, Messrs. H. J. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

For One Insertion—Whole Page, £3; Half Page, £2 10s.; Quarter Page, £1 15s.; One-eighth, £1 6d.

The following reductions are made for a series—Whole Page, 14 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistantships, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per line (minimum 2s. 6d.).

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor, 5, St. Stephen's Place, Westminster, London, S.W. 1; or, if resident in Ireland or to the Dublin office, in order to save time in forwarding from office to office. When sending subscriptions to the Dublin office, the name and address of the person paying should be as applied to the Publisher.

Original Articles on Letters intended for publication should be addressed to the Editor. Each letter is read by at least one of the Editors, and no communication is accepted until it is authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Patrons.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

NOTICES TO CORRESPONDENTS.

Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature or initial, and to give the practice of, signing themselves privately by the name and address of the "Old Subscriber," etc. Much conclusion will be spared by attention to this rule.

Haline Dispensary, Dale Street, Stretford Road, Manchester, Honorary Secretary £100 per annum, with apartments, attendance, coal, and gas. Applications to Honorary Medical Secretary, 60, Farnham Crescent, Salford. 

Falkland Islands.—Assistant Colonial Surgeon. Salary £100 per annum; private practice allowed. Applications to the Assistant Private Secretary, Colonial Office, Bowring Street, W. R. Rockdale, Infirmary and Dispensary—Senior House Surgeon. Salary £125 per annum, with board, residence, and laundry. Applications to Mr. T. Elyea, Kershaw, 11, Bowring Street, Manchester. 

Manchester Northern Hospital for Women and Children, Park Place, Manchester.—Assistant Matron. Salary £100 per annum, with apartments and board. Applications to Mr. Hubert Tooney, Secretary, 39 Barton Arcade, Manchester, Wrexham Infirmary.—Resident House Surgeon. Salary £120 per annum, with board, lodging, and washing. Applications to Frank Nixon, Secretary, 7 Hill Street, Wrexham. 

Ingham Infirmary and South Shields and Westoe Dispensary.—Junior House Surgeon. Salary £115 per annum, with residence, board, washing, laundry, and wages from John Potter, Secretary, Ingham Infirmary, South Shields.

Appointments.

Baird, T. MAINIE, M.D., F.R.S., Munich, Honorary Surgeon to the Manchester Royal Eye Hospital.

Crane, F., M.B., B.S.R.U., Medical Officer of Health to the Llandudno Corporation.

Hewell, James B., L.R.C.P. Lond., M.R.C.S., Medical Officer of Health for Hammersmith.

MacGregor, A. C. M.D., C.M., Edin., Chief Assistant in the Electrical Department at St. Bartholomew's Hospital.

Menzies, W., M.R. I., Surgeon and Demonstrator of Anatomy at Guy's Hospital Medical School.

Rip, J. A., M.B., B.S., London, Medical Registrar to Guy's Hospital Medical School.

Stinson, E. Gerald, M.S., Londo., F.R.C.S.Eng., Assistant Surgeon to the Brecon Infirmary, Brecon.

Toon, A. H., M.B., B.S., Lond., Surgical Registrar and Demonstrator at Guy's Hospital Medical School.

Walker, John, M.D., Ch. Ch., Royal College of Surgeons, under the Factory and Workshop Acts for the Caithness District of the County of York.

Lithis.

Lockwood.—On July 12th, at 19 Upper Berkeley Street, Portman Square, W., to Charles Barrett and Edie Lockwood—a daughter.

McCardie.—On July 12th, at 39 Frederick Road, Edgbaston, Birmingham, the wife of Dr. W. J. McCardie, of a son.

Zoan.—On July 12th, at 27 Carlton House, the wife of Arthur Zoan, M.B., B.S., Lond., late I.M.S., of a son.

Marriages.

Curtis.—Butlin-Brown.—On July 7th, at Fushing Church, the Rev. John Curtis, B.D., to Eda Stanley Butlin-Brown, M.B., B.S., of London.

Davis-Jennings.—On July 7th, at St. Paul's Church, Kingston Hill, Herbert Ross Davies, M.D., of Kingston-on-Thames, to Miss Mabel Sue Ross of Southwark, to Eleanor Alice, only daughter of Mr. and Mrs. W. C. Ross, of the late James Puckle, Hampstead.

Ellison-Puckle.—On July 7th, at St. Peter's, Belgravia, Frank Ellison, M.D., seventh son of the Very Rev. Dean Ellison, late of the Church of England, to Miss Agnes Puckle and Mrs. Puckle, Hampstead.

Fletcher.—On July 7th, at the Parish Church, Arbery, Isle of Man, Robert Myksterley Fere, M.D., M.S., D.P.H., of Castletown, to Dorothy, daughter of George and Edith Parker, of Ballaugh, Castletown, Isle of Man.

Deaths.

Barry.—On July 9th, Lieut.-Colonel D. P. Barry, I.M.S., of the Royal Medical and Surgical, Lucknow, India, aged 72, in India.

Mason.—On July 9th, at 2 York Road, Birmingham, Hugh Herbert Mason, M.R.C.S., aged 66, late of Barking, Essex.

Petts.—On July 9th, of 4 Parkside Gardens, Yvonne, only daughter of Mr. and Mrs. W. G. Petts, late of Bermondsey, to Eleanor Rose, youngest daughter of the late James Puckle, Hampstead.

Benn.—On July 12th, in Aberdeen, Alexander Eith, M.D., aged 74.

Williams.—On July 16th, at The Cottage, Tealforth, Hubert Williams, L.R.C.P. Edin., aged 80.

HULME DISPENSARY.

**A Death from Glanders.**

As interesting tragedy has recently been enacted in a Nottingham colliery village. One of the coal-workers, a man 33 years of age, was taken ill with an acute malady that suggested sunstroke. His fever abated; pains came on in the shoulder and nape of the neck, and after a week, pneumonic symptoms of an asthmic type. An inflammation followed, and appeared in the man’s ankle, and this was followed by an eruption of blebs in various parts of the body. Before death he was seen by a consultant physician, but no positive diagnosis was arrived at. It was only some days after his death that the medical attendant was led to connect the illness with a serious outbreak of glanders amongst the ponies in the pit where deceased worked. It is most interesting to note that neither the colliery surgeon nor the consultant had ever seen a case of human glanders, a fact that affords convincing and satisfactory evidence of the extreme rarity of the disease. Not many years ago the disease was endemic throughout the United Kingdom, and the textbooks of the last generation contained minute accounts of various manifestations. Some five or six years ago a fatal case occurred in London, and others are reported from time to time. Fortunately we have in malaihin a conclusive test as to whether a horse is or is not affected by glanders, so that it is possible to weed affected horses out of any suspected stable.

**Bacillus mallei** as the causative organism of glanders, although it has not so far led to the discovery of a remedy against the disease in man, has provided a diagnostic test in horses. As years go by it may be assumed that all the infectious diseases which now attack mankind will become so rare as to be more or less unrecognisable by medical men, as now actually happens not infrequently in the case of small-pox, typhus fever and plague.

**A Boxer’s Death.**

On the 23rd a boxing contest took place at Maidenhead Hippodrome, when the chief event was a fight for a purse of £25, between Private Eggleston, late of the Royal Berks Regiment, and Bill England, a Reading light-weight. Eggleston, the challenger, is thirty years of age, being eight years older and several inches taller than his opponent. From the first round he had the best of the fight, if, indeed, the contest is worthy of so one-sided an affair. England was advised by his seconds to give up at the end of the second round, but refused to do so. Half-way through he was so distressed and punished that Dr. Ellis, who was in the audience, appealed to the referee to stop the fight. On three occasions England had been almost counted out. The fight was stopped and the boxers shook hands and left the ring unassisted. Later, England became unconscious in his dressing room and died some hours after his removal to the local cottage hospital. Post-mortem he was found to have died of haemorrhage of the brain and to have sustained a fracture of the temporal bone. At the subsequent inquest the jury censured the referee for not having stopped the contest sooner. That view will doubtless be widely endorsed amongst sporting men, but a large section of the public outside that curious relic of barbarous times will go a good deal further, and assert that the whole conduct of these "boxing" matches should be rigorously reformed, or that they should be altogether abolished. The result in England’s case shows that the gloves offer but a flimsy disguise for what is really the old-fashioned prize fight. The palglist of a couple of generations back could not hope to do more than kill his man. Why do not boxers insist upon properly padded gloves, instead of the murderous shams used in modern boxing-matches?

**As an ingenious theory was spun at the recent Conference of the Royal Institute of Public Health at Edinburg**

**Town-bred versus Country-bred Workmen.**

He contrasted the figures of the height and weight of 2,740 men reared in industrial centres at indoor occupations with those of 440 navies, iron workers and salmon fishers who had been born and bred in country districts. As the

SECRET REMEDIES.

The evil wrought by unqualified medical practice is so vast and, indeed, so incalculable that any check to its operations is a matter of deep satisfac-
tion to thinking men interested in the welfare of the community. Some time ago the British Medical Association published a book under the title of "Secret Remedies," criticising the composition, the claims, the therapeutic and commercial value and other interesting details of and concerning a number of largely advertised nostrums. The work ran through several editions rapidly and it has undoubtedly been a thorn in the side of the patent medicine owners, for it has educated the public as to the worthlessness, absolute or relative, of the many preparations foisted upon them with a wealth of exaggerated phrase, if not of brazen and lying effrontery. By reason of its fearless statements the book "Secret Remedies" exposed its authors to legal attack from a whole swarm of nostrum vendors. As a matter of fact, however, if we remember aright, only one of them sought the vindication of the law courts. The plaintiff in that case was Mr. Charles Stevens, the managing director of a company formed for the sale of a specific for the cure of consumption. In a first trial brought against the British Medical Association for the recovery of damages for libel, the jury did not agree and the suit was dismissed. The analysis published by defendant gave krameria as an ingredient, a substance that Stevens declared was not contained in his preparation, the active or curative virtues of which lay in a certain root called umelalo, which plaintiff had discovered in South Africa as a cure for consumption. Some time after the unsatisfactory termination of the first trial a second took place last week, with the happy result that judgment was entered for the defendant Association, with costs of both trials. The case was heard at great length, but only a few of its many points of interest can be considered here. The plaintiff said that he had made £1,000 per month from the sale of his "cure" in Capetown. He was prosecuted for doing such things as belonged to the medical profession and was fined £10 in the first case and £25 in the second. After these prosecutions he set up business in the United Kingdom, where by a grotesque anomaly characteristic of our imperial legislation he was safe from prosecution. The exposure that was effected speedily and effectively in our colony could be brought about in our own country only at enormous cost incurred by a public-spirited professional association. No better illustration of the farcical state of British law with regard to the sale of secret remedies could be desired. Some of the medical testimonials published by plaintiff illustrate the necessity for drastic changes in the law. One, for instance was from a man not on The Register, but who was none the less debarred from advertising his opinions under the description "M.D." on a medical matter. It may be pointed out, by the way, that under existing law it is more than probable that the Royal College of Physicians could have seized and destroyed the whole of Mr. Stevens's stock of so-called "remedies." Anyway, it is a scandal to our national commonsense that
medically untrained persons should be permitted to amass huge fortunes by professing to cure disease by means that are, scientifically speaking, often nothing more than worthless impostures. Much more might be said about this interesting libel action, which marks an epoch in the history of the statutory campaign that King Henry VIII. inaugurated against "false remedies and false potions."

One last comment we have to make arises from the rumour that it is possible, in the failure of the plaintiff to pay costs, that the whole expenses of the two suits may fall upon the members of the British Medical Association, the resources of which have been seriously drained by legal expenditure during the past few years. Whatever may happen in the present instance it is a gross defect in administrative law that anyone should be able to bring actions for libel without any possible prospect, in the event of non-success, of paying the expenses of what is to all intents and purposes that bugbear of society, a speculative law-suit. The British Medical Association, whatever its faults in other directions, deserves the gratitude of the medical profession for its public-spirited action in the matter of "Secret Remedies."

THE PUBLIC AND UNLICENSED PRACTITIONERS.

In our present state of social enlightenment the fact that legally unqualified persons are allowed to discharge medical functions constitutes a standing reproach to our national prudence. It must be generally conceded that so intricate and responsible a science as that of medicine demands special education and experience from those who profess to offer its advantages to the community. Henry VIII. first recognised the necessity of State medical qualification whereby the public should be enabled to distinguish between the genuine practitioner and the charlatan. He bestowed large powers upon the London College of Physicians for the seizure of false medicines and for the punishment of false practitioners. Some of these provisions were strengthened in subsequent reigns, and, so far as the state of affairs is concerned in the present day, they occupy the position of un repealed laws. There is reason to believe that were the Royal College of Physicians of London to exercise its powers, it would be able to purge the metropolis, if not the major part of England, of a large proportion of its quacks and quackery. So far as the art of surgery is concerned, a famous Act of Henry VIII. (anno xxxv. Hy. VIII.), which established the conjoint Company of the Barbers and Surgeons of London, contained an unfortunate exception, which to the present day provides a loophole through which many an offender escapes. The clause setting forth this exception, on the authority of Christopher Merritt, Fellow and Censor of the London College of Physicians, writing in 1660, runs as follows:—

"Be it ordained, established, and enacted by the authority of the present Parliament, that all time from henceforth it shall be lawful for every person being the King's subject, having knowledge and experience of the nature of herbs, roots, and waters, or of the operation of the same by experience or practise within any part of the Realme of England, or within any other of the King's Dominions, to practise, use and minister in or to any outward sore, unsafe, wound, opisthumacioue, outward swelling; or disease, any herb or herbs, oynments, bathes, pulites, and emplasties, according to their cunning, experience and knowledge in any of the diseases, sores and maladies aforesaid and are otherwise into the same, or drinks for the stone, or strangury, or ague, without such vexation, trouble, penalty or loss of their goods. The forsaid statute in the forsaid third year of the King's most gracious reign, or any other Act, ordinance or statute to the contrary hereof, heretofore made, or in any wise notwithstanding." To this exception was appended a momentous condition that appears to have escaped notice in many prosecutions where the above clause has been pleaded in defence. The Act provided that the exception applied only to those who gave their help without fees for their "pains and cunning, but have ministered the same to poor people only for neighbourly and God's sake, and of pity and charity." This point about payment has led to many evasions, which might perhaps have been not infrequently brushed aside by a prosecutor armed with the necessary determination and resources. The whole question cannot, of course, be entered into here, but it may be stated briefly that, in the existing law, there are wide powers for the suppression of quacks and quackery. The obstacle to their application lies chiefly in the lack of a prosecuting body. The Royal Colleges have betrayed their trust: the comparatively modern General Medical Council is too wound up in its own narrow field to seek to extend its penal powers to the prosecution of unqualified practice—although, be it noted, such powers, even if they do not actually exist, could be readily obtained. A curious apathy, indeed, appears to ensnare the question which was handled so boldly by bluff King Hal some four hundred years ago. Even the Select Committee of inquiry into the proprietary medicines has strangely neglected the historical side of the problem, which is none the less vital to its proper understanding. Clearly, some drastic revision of the situation is needed in order to defend the health of the people from the snares of reckless and ignorant quackery.

CURRENT TOPICS.

The Prince of Physicians.

At a recent meeting of the Section of the History of Medicine of the Royal Society of Medicine, Sir William Osler put forward a plea for the restoration of the tomb of Avicenna at Hamadan, which is in ruins. He also broached the subject at a meeting of the Persia Society the other day, when
Professor Margoliouth delivered a striking address upon the celebrated tenth-century Arabian physician. Born near Bohkara in 980, it is said that at the age of eighteen he had learned all the science of a physician. It is not a little remarkable that the philosophy, metaphysics and science of this Persian "Prince of Physicians" should dominate the intellectual life of Islam for four hundred years as a consequence of the Aristotelian and Platonic systems. His principal work, the "Canon of Medicine," controlled for close on half a millennium the principal medical schools of Europe. It was written in Arabic and was early translated into Latin. In addition to this monumental work Alivccba also wrote a hundred large formulae dealing with various philosophical and scientific subjects. The proposal that the Persia Society should undertake the repair of his tomb seems to be a most fitting one, and it is not unlikely that the Section of the History of Medicine of the Royal Society of Medicine might be willing, together with the corresponding French Society, to contribute towards this worthy object. It is understood that the official permission of the Persian Government has been received and that a sum of £600 is needed towards the restoration and upkeep of the tomb of the "Prince of Physicians."

The Vice of Versatility.

The commonalty of mankind can grasp but one idea at a time, and it is duly suspicious of those who can do otherwise. It views any tendency to catholicity of temperament with undisguised misgiving, and loves the man with the label. This primitive and unfortunate fact especially affects the medical profession. A man is labelled "doctor," and there he ends. People know that he is a doctor and that he cannot be anything else. If he tries to be something in addition he cannot be a really good doctor. In the eighteenth century there were men who could fairly encompass the sum of human knowledge. Now we specialise. And just as we are beginning to see that undiluted specialization is not the ideal of human activity, confidence in its infallibility has permanently permeated the popular pericranium. Anyone who has escaped his label is distrusted. Weir Mitchell was branded as a neurologist and had to live down a subsequent reputation for literary efficiency. There are many medical men who would stray out of their grooves, and they dare, but they know the penalty. An observer's understanding is limited by his attainments, and so the man in the street misjudges. He thinks that the man of outside abilities cannot be much good at his profession and forgets that men may toil upward in the night while their companions sleep. The wings of genius, instead of bearing men aloft, often encumber them on the earth. Once, a man is classified and marked by the world he progresses at his peril. These people who will not stop growing are nuisances. They develop new characters and embarrass their fellow-men. The world in general does not think more than is absolutely necessary, and labels save thought. That is why they are so popular. Their influence is had all the same. A mind, blind, crammed, confused by other people's limitations is of less value even than one which negatives its efforts by the multiplicity of its exercises.

Workmen's Compensation and Medical Science.

The Workmen's Compensation Acts have presented many a knotty problem to the law courts. In that way they have achieved a good deal by way of educating the public and the legal profession, and of drawing the attention of medical men to various scientific points of more or less obscurity. Not long ago a case was reported in which a workman claimed permanent compensation on the ground that, while laid up as the result of an accident, he had grown so fat as to be unable to follow his occupation. His ingenious claim was unsuccessful in court. Last week a more plausible claim was tried by the Alfreton County Court Judge. A miner was certified in May, 1912, to be suffering from miner's nystagmus, and was awarded 148 per week compensation, payment of which was continued until January 28th, 1914. It appeared from the medical evidence that after a time the plaintiff's mental condition underwent serious changes—he became morose, and developed symptoms first of neurasthenia and later of melancholia. The question raised was whether the insanity arose out of the nystagmus. A good deal of evidence was forthcoming, but the judge eventually dismissed the application. Most medical men will agree with the view that there is no connection between nystagmus and insanity. From a scientific point of view a great deal of valuable material is wasted in the County Courts, where the conflict of medical testimony is the more or less necessary. All such evidence should be presented, in our opinion, as the report of an official body of investigation.

Dogs and Tramcars.

In the midst of a mass of padding in the daily papers about the Irish question and the cricket championship, and such like matters of high politics, there is still room for the things that move humanity, the straws that show which way the wind blows, the unsophisticated outpourings of the human heart, the letters to the Editor. And the subject is dogs. Should dogs ride in tramcars? If not, why not, and if so, why? Municipalities and powers differ. Some welcome our dumb companions as personal luggage, others charge him a penny—these latter mostly in Scotland, where they even refer the traveller to the book of Proverbs in the hope of encouraging him to proper tramcar behaviour. The money is not much, but it makes the dog go. Dogs, looked at in the light of tram travellers, have two points of view—scientific and sentimental. The standard is determined by the ownership or non-ownership of a canine companion. Sentiment begs his dog to be loved as himself, and to share the other collateral privileges of a freethorn Briton. Science points out a pullicose polyvarious pest, a purveyor of plagues and promiscuous propagator of pulking pups. And that is the view we should take up. We are under a canine tyranny of sentiment. Our own life is perfect, and to get other people to admit it we must grant the same to theirs. We are all slaves to a conspiracy of canine content. We know that the dogs in the street do not improve the edibles so recklessly displiced on the ground level. Yet we tolerate them. We know that dogs may carry disease—they are proverbially unclean—but because they are our personal parasites we suffer all manner of ills for their sake. All for sentiment—the great unreasoning power of reaction—the brake on the progressing world. We know it is unworthy of us, but we suffer it for the sake of flattery. The dog is the only animal that has found a god, and deity is not our everyday estate.

The Treatment of Early Mental Disease.

The change in our attitude with regard to the management of the insane, which is so striking a feature of modern medical opinion, reflects itself in
a noteworthy manner in the deputation which waited upon the President of the Local Government Board the other day. The object of the deputation was the presentation of a memorial, signed by many leading members of the medical profession and by numerous Members of Parliament, asking the Board to enable and encourage local authorities to supply and establish homes for the treatment of cases of temporary or incipient insanity. The need for such homes has long been felt for patients not demanding certificacy, for entrance into them would be purely voluntary and without compulsion. It was urged that these institutions should not be regarded as half-way houses to asylums, and that in order to encourage the public to come to them for early treatment, they should be kept outside the jurisdiction of the Board of Control under the Mental Deficiency Act. Emphasis was laid upon the alarming accumulation of the registered insane in the asylums, and it was stated that as insanity was not being checked by the present methods, it was necessary to attack the causes of early mental instability. The preventive measures proposed would not only be a great gain to the community, but would reduce the expenditure on costly asylum accommodation, which was such a heavy burden on the rates. As Dr. Chapple pointed out, the idea that insanity is a mental disease, and therefore to be treated in hospitals for the purpose, should be popularised. It is gratifying to note that Mr. Samuel, in replying to the deputation, proposed to ask the medical department of the Local Government Board to make a special study of this problem, to inquire into the experience of similar action which had been taken in Scotland, which appears to work so well, and to get into touch with the Board of Control with a view to his taking administrative action. If fresh legislation in the matter be not possible at the present juncture, the administrative machinery of the Board may be so altered, therefore, to be set in motion in the near future.

**Dublin Water Supply.**

Most of the world's distress is, in our opinion, due to lack of imagination, and the rest of it is due to a failure to realise in action those imaginings on which safety and progress depend. The case of the intelligent man does not get away from the idea that what is will continue, and that men picture themselves in other circumstances than those in which they are. Man is not a reasoning being; or, if he reasons, he gets no farther than the statement of premises—he shies like a nervous filly at the only logical conclusion. He does not believe in logic. He may even state his logical opinion in correct terms, but he does not believe what he is saying. People believe only what they do, there is no action divorced from belief. Belief is not an independent mental process, it is action. There is always a mental reservation in the mind of a man who says he believes this course would be the better but who takes the other course. He thinks in his heart that the other course is the better, perhaps because the stars in their courses will fight daily in the sky, because effect does not always follow cause in his experience. Any individual in Dublin will say that the water supply must be conserved, and that a daily consumption of 14,000,000 gallons at present will bring a drought, yet the collective mind does not see why any action should be taken, for 14,000,000 gallons are being consumed daily in spite of repeated warnings issued by the city engineer and by the engineer in charge of the water supply. The necessity for conserving the supply has never been greater since the drought of 1893; everybody talks, nobody does. There is more faith on earth than preachers dream of.

---

**PERSONAL.**

Dr. W. D. MURRAY has been elected President of the South-West London Medical Society for the ensuing year.

Dr. G. FLEMING, M.B., C.M., M.R.C.P. Edin., has been appointed Medical Superintendent to the Darum County Sanatorium.

Dr. F. W. CRAIG has been appointed Medical Superintendent Officer of Health, and also Tuberculosis Officer, for the city of Derry.

Dr. KNOWLES BONNEY, M.D., was presented with the Savill Memorial Medal last week at the West End Hospital for Diseases of the Nervous System.

Mr. M. W. B. OLIVER, M.A., M.B., B.C. Cantab., F.R.C.S. Eng., has been appointed Assistant Ophthalmic Surgeon to the Miller General Hospital.

The following medical practitioners in Hull have been placed upon the Commission of the Peace for the city—Dr.s. Frank Nicholson, George Gaultby, and Mr. C. H. Milburn.

Dr. ALEXANDER H. MACKLIN, Senior Surgeon to the Blackburn Infirmary, has been appointed as one of the surgeons in Sir Ernest Shackleton's forthcoming Polar Expedition.

Sir RONALD ROSS, K.C.V.O., F.R.S., will deliver the biennial Huxley Lecture at Charing Cross Hospital Medical School upon the occasion of the opening of the winter session thereon on October 1st.

A complimentary dinner was given the other day at Oxford to Mr. Horatio P. Symonds, Senior Surgeon to the Radcliffe Infirmary, upon the occasion of the presentation to that institution of a portrait sketch by Mr. J. S. Sargent, R.A.

Dr. AND MRS. SCELROCK, of Trededgar, were the recipients lately of a handsome presentation from their many friends and patients in the George-town district as a token of the respect and esteem in which they are held by all classes.

Dr. JOSEPH GESANI, of Cork, was presented the other day with a handsomely illuminated address and a silver tea set by the Grand Order of Israel (Sion Lodge) in token of his valuable services rendered to the society for a period of over 25 years.

A presentation of a Belize two-seater motor-car was made on the 14th inst. to Dr. Enyr P. Price, of bangor, in recognition of his services to the North Wales Branch of the British Medical Association, particularly in connection with the National Insurance Act.

Dr. J. MATHESON LAWRIE, the Medical Superintendent of the Princess Christian Hospital and Sanatorium at Weymouth, was presented last week with his portrait in appreciation of his services. Mrs. Lawrie was presented at the same time with a service of plate.

Dr. THOMAS CUNNINGHAM PENFOLD, M.B., Edin., D.P.H., Medical Officer of Health for the Hexham rural district and for the Prudhoe urban district, has been appointed to succeed Dr. J. Finlay Macdonald as Medical Officer of Health for the Auckland rural district.

Dr. JAMES NIVEN, LL.D., M.B., Medical Officer of Health for Manchester, was the recipient last week of the gold medal awarded annually by the Council of the Royal Institute of Public Health to a public health official "in recognition of conspicuous services rendered to the cause of preventive medicine within the British Empire," more especially in connection with his work in the direction of the prevention of tuberculosis.
MEDICAL practitioners are often consulted on the subject of corpulence, as the inconvenience is obvious, and the late K. A. Proctor, the well-known writer and lecturer on astronomy, graphically described his own condition as being like that of a man who was wearing three overcoats with the pockets loaded with stones. Yet in spite of their sufferings comparatively few are willing to persist in the regimen necessary not only to reduce their weight, but to maintain it at a proper level. They are content to follow a course of diet for a few weeks, and they get off a few pounds either by visiting a German watering place or by following the directions of a medical adviser at home, but after a longer or shorter time they fall back into their former habits and speedily regain the weight lost.

It is usual to divide these cases into two great classes, the plethoric and the anemic, and these correspond to clinical conditions that can be readily recognised.

The plethoric type consists usually of well-grown, well-developed persons who enjoy the best of health and are often active and vigorous, by no means disinclined to take exercise, and frequently decidedly athletic and good at games. The tendency to corpulence usually shows itself soon after thirty, or even before, and increases with age. They generally suffer from akoria—that is to say, the excessive appetite which results from absence of the feeling of satiety, so that without being especially hungry they eat an unnecessarily large amount of food. This condition is usually hereditary, a family history of obesity being discoverable in something like two-thirds of the cases; and it is often also associated with a family history of gout, renal colic or gall stones. They are decidedly eupetic individuals, who enjoy life, and at least up to middle age possess the best of health, but after passing forty they begin to manifest such disorders as acute gout in the great toe or in some other joint, or albuminuria or glycosuria. In the latter half of life they frequently develop Bright's disease or diabetes, and on the whole we may regard this form of obesity as a condition by no means favourable to longevity; they die at or soon after sixty as a rule. The type is fairly equally distributed between the sexes.

The anemic type of obesity is more common in women than in men. It may be induced by anything that causes ill-health, supervening not uncommonly after a serious illness, such as typhoid fever. The subjects of this form of obesity, unlike the former class, are not, and do not look, as if they were in good health. They are pale, flabby, and disinclined in their appetites, and they suffer from minor ailments, such as constipation, dyspepsia, headaches, menstrual irregularities, or catarrhs, but they are less prone to develop the graver constitutional forms of disease met with in the plethoric group.

The aetiology of the two groups is essentially different; in the former there is merely an exaggeration of normal metabolic processes, a sort of excess of what happens in all healthy persons. The formation of fat is a physiological process which is more marked under certain conditions. The young girl at puberty normally puts on a layer of fat which rounds her form and conduces to the beauty of her figure at that time of life, while boys at the same age are thin, and remain so for another ten years. Bouchard showed that at the age of seventeen the consumption of carbohydrate to the pound of body-weight is 54 grs.; while at the age of twenty-five it falls to 42, the balance of unconserved carbohydrate being usually stored up as fat. After this age there is a progressive failure in sugar consumption associated with a gradually increased weight, so that at the age of sixty the sugar consumption falls to 38 grs. per lb., and although these figures are of course subject to individual variations they illustrate the general rule that after thirty most people tend to accumulate fat. The extent to which they do this doubtless depends upon their habits, as to, on the one hand, the amount of exercise taken, and on the other the amount of food consumed. Rubner's scale is generally accepted as expressing the requirements of the normal body; a man doing a moderate amount of work requires 41 heat units for each kilogram. (2 lbs.) of bodyweight, so that a person weighing 70 kilorgms. (to st.) would require daily about 3,000 heat units; but this quantity is easily exceeded. For example, beer readily supplies a large amount of nutrition, in round figures about 400 heat units or great calories to the pint, so that it is not surprising that those who not only live well in the matter of food, but drink in addition two or three pints of beer daily, accumulate a large amount of fat. It is not only beer that is fattening from its combination of carbohydrate with alcohol, for even sugar whiskies give 155 heat units to the ounce. Obviously it is easier to take an additional 1,000 heat units in the shape of beer than in the form of whisky, for while two and a half pints of beer would be regarded by most persons as a strictly moderate allowance, a daily dose of half a pint of whisky would be generally considered to verge on intemperance. Although fat supplies by far the largest amount of heat units it is rarely to be blamed for producing corpulence amongst English people, as their taste for this article of food is limited. It is generally to over-indulgence in carbohydrates that corpulence must be attributed, and these are chiefly eaten as bread. Most stout people are great bread eaters, and if bread is eaten with butter its effect is the more likely to be pronounced. As already stated, these people live vigorously; if they are hearty eaters they, as a rule, lead by no means sedentary lives, but take a fair share of exercise; in fact, they sometimes complain that the more exercise they take the more they eat and the stouter they grow.

If this is a correct account of the causation of these cases the principles of treatment are simple. All we have to do is to reduce the number of heat units consumed daily. The diet must be restricted according to scale, allowing, for example, 50 heat units per kilogram of body-weight, but we must bear
in mind that in the case of an obese person we cannot allow them to reckon their actual weight, but the diet must be based upon what they ought to weigh. The French have a simple known as Quetelet’s, which allows for every cm. over 1 m. in height 1 kilogram of bodyweight, but as we do not use these convenient weights and measures we may prepare a scale for ourselves something like the following:—

</table>

Having measured the patient’s height and deduced his proper weight, we may allow a dietary giving 30 heat units per kilogram of bodyweight as the maximum, and this should be reduced month by month until the patient is getting instead of 1 meal that unit daily 1,500, or even less, but the effect of the diet must be watched, and something must depend upon the patient’s mode of life, for if compelled to be fairly active it is not possible to reduce the food in the same way as where he can be kept at rest. Thus in a case recorded by Delboeuf the patient, who weighed 234 lbs. (his height is not given), was kept on bread and his diet at first consisted of two quarts of milk daily, equal to 1,400 heat units; this was reduced to one and a half quarts, then to one quart, and finally to less than a quart daily, upon which diet at the end of seven months the patient had lost altogether 54 lbs., and was reported to be in perfect health. Such a regimen is obviously only possible under exceptional circumstances. The man had been unable to work, and was content to be admitted to a hospital where the treatment was carried out without any consideration for its duration, nor does there seem to have been any difficulty in persuading the patient to submit to a monotonous regimen which was almost equivalent to starvation. Most of our patients insist upon the use of food, and it is the duty of the physician to afford them this in any arrangements he may make for them. If we consult a diet table which should give the value of all ordinary articles of food in their contents of protein, fat and carbohydrates, and their calorific value, it will be found that it is easy to construct a diet which is made up of a variety of vegetables and fruit, cutting down the carbohydrates and fat, and allowing a reasonable quantity of animal food, so that without exceeding 2,000 heat units daily a sufficiently palatable dietary may be prepared. But it must be remembered that the ordinary British palate cares little for fruit and vegetables, and that the British housewife or plain cook possesses little skill in their preparation so that success depends in no small degree upon our ability to enlist the cooperation of not only the patient, but of his cook.

The following diet table is constructed to allow about 2,000 heat units, and will permit of being reduced 500 or so for the sickly and thin. Pre- tene biscuits for the brown bread at breakfast and tea:—

**Table I.**

This diet contains, roughly, about 2,000 heat units.

**Breakfast.**—Tea or coffee without milk, cream, or sugar; a slice of lemon or saccharine may be used if desired; half a Brusson Jeune roll or a piece of Hunter and Parkinson’s biscuit, or 1 oz. of toast, with butter; 1 or 2 eggs; any lean meat, game or fish; any salad or fruit in season.

**Luncheon.**—No soup; one dish of lean meat, poultry, game, or fish, with salad or green vegetable or 1 lb. of potato, artichokes, or peas; an omelette or stewed fruit of any kind sweetened with saccharine; a slice of bread and a piece of chocolate biscuit; no butter; water or mineral water but no alcoholic drink; black coffee sweetened with saccharine.

**Tea.**—One or two cups of tea with a slice of lemon, but no milk, sugar, or cream; half a Brusson Jeune roll or 1 oz. of toast with butter.

**Dinner.**—The same diet as at luncheon; any fruit at dessert; black coffee sweetened with saccharine.

**Table II.**

This dietary contains, roughly, about 1,500 heat units; without the whisky about 1,400; without potato, butter, or cheese about 1,100; without bread or toast 900.

**Breakfast.**—A breakfast dish of tea or coffee with 1 oz. milk, no sugar; 3 oz. brown bread, toasted, no butter; 3 oz. white fish—sole, haddock, cod; 1 egg; or alternatively 2 oz. lean ham; lettuce, watercress, or a tomato.

**Lunch.**—Six oz. lean beef or mutton; 3 oz. potato; 3 oz. cheese; Prolacto biscuits; 1 oz. whisky with water or mineral water.

**Tea.**—Tea with 1 oz. milk, no sugar; 2 oz. brown bread; 1 oz. fresh butter.

**Dinner.**—No soup; 3 oz. white fish with anchovy or Worcestersauce, but no butter; one small potato; 3 oz. mutton, veal, chicken, pigeon, turkey, pheasant, or partridge; cabbage, cauliflower, French beans; stewed fruit, sweetened with saccharine; savoury of fish or egg on a small piece of toast; 1 oz. whisky with water or mineral water; no other bread or toast, but one or two Prolacto or Proteine biscuits if desired.

It is probable that the anemic type of obesity depends largely upon the retention of chlorides and the consequent hydration of the tissues by Dr. H. Iscovestie on Hydration in Obesity. This is the property by which gelatine, membrane protoplasm, and similar tissues attract and retain water, and the amount of water so absorbed is very great, amounting to as much as five times the weight of the original sheet of gelatine used in the experiment. This process is affected by certain salts, being favoured by the chlorides of potassium, sodium, and ammonium, as well as by nitrate and sulphate of soda, while it is hindered by acetates and tartrates. In this connection it is interesting to remember that vinegar, citric acid, and citrates are popularly supposed to be remedies for obesity. Some of the advertised cures contain a certain proportion of bicarbonate and chloride of sodium, which would not favour the reducing process, as in fact Marcel Labbé has recorded a case of diabetes that became cedematous when taking 40 gms. (600 grs.) of bicarbonate of soda daily for a week. This form of obesity should be regarded therefore as a sort of cædoma and calls for treatment based upon the avoidance of liquids and of those articles of diet, especially those that result, which favour the retention of water. For such cases the Schroth diet as followed at Lindewiese might be tried in properly selected cases. This cure is not popular, as it calls
for a good deal of self-restraint. Each night the patient should sleep in a partial or complete cold wet pack, but where he objects strongly to the direct contact of the cold, the body may be wrapped in a thin dry sheet and then in the wet sheet, which is covered by a blanket and one or two eiderdowns.

The chief feature of the diet is the strict and absolute abstinence from all alcohol for a number of days. The amount which should extend from half a day to five or six days according to the case. A beginning may be made by abstinence from any liquid at the mid-day meal. The second point is the periodic use of wine as a drink, and upon this considerable stress is laid; it is believed that both the soups and the dinners should be sweetened as well as by its alcohol. No water may be drunk during the cure, indeed its use is said to be attended with danger, but in the early stages of treatment barley water or thin gruel or a cup of cocoa is allowed. The wine generally prescribed is a thin, light, rather acid country wine, either red or white; probably a low-priced still Moselle answers the purpose as well as it can be realised, if an attempt is made to carry out the cure in this country. The third point is the reduction of the amount of food, especially of the fats and proteins, while fruits, vegetables, and cereals may be eaten at discretion. Schroth is of the greatest stress upon the necessity of a thick diet of grains, especially in the patients living and sleeping as far as possible in the open air. At the commencement of the treatment breakfast should consist of two or three dry rolls or a cup of cocoa; at midday one or two tablespoonfuls of oatmeal porridge, rice or sog pudding, or under certain circumstances a small meal of bread or potatoes, and fruit compote, but nothing is allowed to drink; at night two or three rolls or bread and milk. During the first few days the patient may take a few mouthfuls of drink made with barley or oatmeal, lemon juice, and sugar, but later on this must be replaced by wine, which may be at first diluted with water and sweetened, but afterwards should be drunk absolutely pure. The quantity of wine may vary from 7 to 15 oz. daily. Liquids should be taken about four hours after food, but never at meals; with the liquid the patient may, if he desire, take a few mouthfuls of bread or biscuit. This stage of the treatment lasts from three to five days. In the stage of the second week, which should now be complete, is continued, while the food is restricted to five or six rolls daily, weighing altogether less than 3 oz., and being therefore equivalent to no more than 200 or 300 heat units, but under certain conditions the patient is allowed to take some boiled oatmeal or rice in the middle of the day, and after a course of dry days, which varies from one to four or five the patient is allowed to have one drinking day, and it is usual to begin by taking the wine warm. This stage lasts from three to five weeks, and it is then followed by a pause lasting five or ten days. Finally, the patient enters upon the third stage, which consists in a gradual return to normal conditions of life. Every case requires to be treated according to its special condition, and the method in line which could hardly be carried out satisfactorily away from Lindewiese, or in one or two special establishments in Germany, where the same principles are followed. It is not called a fasting cure, but it is an exceedingly low diet, comparable to the fasting methods that are popular in the British States, but differs chiefly in the restriction of liquids.

The advocates of the Schroth cure maintain that it not only differs in this respect from the simple fasting cure, but that it is much less dangerous, as the tissues are not completely starved, and the temporary restriction of liquids stimulates the vitality of the cells. It is said to be easy to carry out, calling for no apparatus which is not available in any ordinary household, as it is easier to give a wet pack than a bath, and this is especially the case with corpulent persons who are not easily moved. It is further said to increase the number of red blood corpuscles and to presage a permanent cure of anemia.

Myxedema is a form of obesity which has been definitely shown to be due to the deficient action of the thyroid gland. Although the patients take only a small amount of food they nevertheless gain weight, and there is a great analogy between such cases and many of the examples of anemic obesity in which the symptoms are commonly met with. In myxedema atrophy of the thyroid gland is a distinct feature, and in the absence of this symptom such a diagnosis would be doubtful, but it is quite probable that in many of these cases, though there may be no reduction in size, the function of the gland is depressed. This view is supported by the fact that the administration of thyroid gland has been found useful in many cases of obesity; this treatment, which was introduced more than twenty years ago, has been discredited by the abuse of the remedy by the over-large doses which patients took in their anxiety to produce a rapid effect; but there has been no failure on the part of experienced practitioners to introduce the treatment—a dose of 0.25 to 0.5 grains being used. The cure, which is doubtful, is the cure, is attended by a loss of weight.

Myxcedema is a form of obesity which has been definitely shown to be due to the deficient action of the thyroid gland. Although the patients take only a small amount of food they nevertheless gain weight, and there is a great analogy between such cases and many of the examples of anemic obesity in which the symptoms are commonly met with. The cure, which is doubtful, is the cure, is attended by a loss of weight.

This diet contains about 1,500 heat units; it may be reduced by gradually omitting the roll or breakfast biscuits, which may be replaced by Protene biscuits.

**Breakfast.**—Fresh fish or fresh meat with any green vegetable; 2 Huntley and Palmer's breakfast biscuits, or half a Brusson Jeune roll; nothing to drink; no salt; 2 hours later half a pint of hot water with a slice of lemon in it.

**Dinner.**—Lean beef or mutton, chicken or white fish; any green vegetable or salad; any stewed fruit; 2 breakfast biscuits, or half a Brusson Jeune roll; no butter; nothing to drink; no salt; 2 hours later half a pint of hot water with a slice of lemon in it.

**No tea.**

**Dinner.**—No soup; any white fish; any meat, poultry, game, any green vegetables; any stewed fruit; savoury; 1 breakfast biscuit; no salt; nothing to drink.

If more bread substitutes are required a few Protene, Protaco, or Karali biscuits may be taken. Before going to bed half a pint of hot water with a teaspoonful of sodium phosphate should be sipped slowly.

**Karell's milk cure may be employed for the treatment of obesity, but as originally prescribed it is not very appetising. During the first week the patient gets every four hours a glass of skimmed milk from 2 to 7 oz. in amount, which in winter may be warm, and water or mineral water is allowed in addition. In the second and third weeks a little toasted white bread and a small portion of salt herring is added, and after one or two weeks of this regimen the milk at one meal during the day is omitted and soup is substituted. This treatment should be continued for five or six weeks, and the use of stewed prunes and baked
apples is allowed in order to overcome constipation. As this diet consists at most of a quart of milk a day the calorific value is very low, and the patient must be nearly starved. In Jacob's modification for the first week the patient is allowed 14 pints of milk daily, given in divided doses, and for the next few days is given an egg in the morning and a biscuit at night; then gradually two eggs, a little minced meat, vegetables and rice pudding are added. At the end of twelve days the patient returns to his ordinary diet, but the amount of liquid should not exceed 12 pints daily for the next few weeks.

Dr. Gulisch is to give very little food after the midday meal. Thus, for example, at breakfast the patient takes a cup of tea with bread and butter, and if he is so hungry that he cannot wait for lunch he may have an egg with a small slice of bread and butter at ten o'clock; at one o'clock the meal is composed of meat, vegetables, salad, and stewed fruit; tea time, coffee with a biscuit, or bread and butter; in the evening nothing but a small piece of bread and butter. It is important that the quantity of food at breakfast and luncheon should be sufficient to satisfy the patient. Under this regimen he claims that his patients lose regularly 1 or 2 lbs. a week.

The cases falling in the second class are undoubtedly more difficult to treat than those in the former group. They require much more supervision, and there is greater risk of doing harm instead of good by altering their mode of life. Changes in the diet should be made gradually; remedies should be prescribed with care, and their effects carefully watched; any complications should be sought out, and if possible removed, and the assistance of fresh air, especially of mountain or sea air, should be secured. As many of these patients are unable or disinclined to take active exercise, massage and passive exercises are extremely useful. In the present day in all large centres there is no difficulty in obtaining the services of well-trained operators who can carry out Swedish exercises, and at most watering places both at home and abroad there are institutions at which these can be obtained. An ingenious adaptation of faradism to produce the effect of general muscular exercise is the "Biocathode," which is in fact a large electrode, the patient being fastened by means of sandbags, and the current when turned on stimulating the contraction of all the muscles. From what I have seen of it its application does not appear to be unpleasant, and it is claimed to effect a rapid reduction in body weight, but it has been in use too short a time for a final opinion as to its value to be expressed.

Note.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Edmund Castley, M.D., Cantab., F.R.C.P., Lond., Senior Physician to the Metropolitan Hospital, and to the Belgrave Hospital for Children. Subject: "Abdominal Tuberculosis."

ORIGINAL PAPERS.

A CASE OF TUBERCULAR IODISM SIMULATING GUMMA OF THE EYELID.

By SYDNEY STEPHENSON, M.B., C.M.,
Edin R.C.S.,
Ophthalmic Surgeon to the Queen's Hospital for Children, King Edward's Memorial Hospital, etc.

GEORGE W., aged 30, attended my out-patients at the Kensington General Hospital for the first time on December 4th, 1907.

The following history was given by the patient—gonorrhea in November, 1906, lasting until March, 1907, that is to say, longer than any other gonorrhoea from which the patient has suffered. Towards the middle of March, 1907, a spot came out on the right knee, and was followed by others on the forehead, right forearm, left upper arm, and towards the end of that month, by "sores" upon the legs. In June or July last the patient's throat became ulcerated.

On August 14th the patient consulted Dr. David Walsh at the Kensington General Hospital. A diagnosis was made of tertiary syphilis. The notes which follow were transcribed from the patient's case-sheet:—"No sore throat or headaches. Primary sore last Easter. Treated with mercury since. Large crusty serpiginous syphilide on left thigh. Others have left pigmented superficial scars."

When I saw the patient on December 4th, 1907, his condition was as under:

The outer half of the left lower eyelid is red and swollen but not tender. At first sight, the appearances reminded one of an abscess in the substance of the eyelid. On palpation, however, it was obvious that the tissues of the lid were infiltrated, and the condition recalled a gummatous process. Another infiltrated area was present in the substance of the left cheek, one inch or so above the upper lip. Below the left jaw was a carnivorous look and a discharging pap by several fistulae. The right ear showed a scaly eruption, not unlike eczema. On the back of the scalp, situated over the occipital bone, was a crusted sore. A number of pigmented, supple, superficial cicatrizes, possibly the remains of cutaneous gummata, present over right knee, both legs, left thigh, left buttock, and right forearm.

The infiltrated lesions of the lower lid, cheek, etc., closely resembled gummata, but on reading Dr. Walsh's notes, it became quite clear that they represented that rare form of iodism known as "tubercular iodism."

Dr. Walsh's notes ran as follows.—The patient was treated locally with ammoniated mercury ointment and internally with potassium iodide (grs. 10) and citrate of iron and ammonia (grs. 10) thrice a day. His attendances at the Hospital were somewhat irregular, having been registered upon the following dates: August 28th, September 25th, October 19th, and November 16th. On the last-named date the potassium iodide was discontinued owing to the existence of "well-marked iodide papules face, etc."

The patient stated that a small swelling, an "iodic papule," had existed towards the centre of the left lower eyelid for about a fortnight, and that the swelling had become greater during the three days before he consulted me.

PROGRESS AND TREATMENT.

Boric lotion and oleate of mercury (10 per cent.) were prescribed to be applied to the affected lid.

December 11th, 1907.—The left lower eyelid is now tender, and the disease process has extended to the whole of that structure. There is definite ulceration of the upper aspect of the outer end of the swollen lid.

December 14th, 1907.—The outer half of the left lower lid is now ulcerated, and the rest of the lid is infiltrated. The parts are tender. The
likeness to a gumma becomes more and more pronounced. Sajodin, one gramme twice a day, administered internally, and the ulcerated surface to be treated with iodiform.

December 18th, 1907.—Condition, as shown in the coloured sketch, has improved. The left lower lid is occupied by a reddish swelling, more marked in the outer half than elsewhere, and the parts are slightly tender. A shallow ulcer, with clean-cut non-indurated edges and nodular floor, occupies the upper part of the outer half of the affected eyelid. It measures 3 cm. by 1 cm. The other sores, one on the left cheek and the other below the left side of the chin, are also in process of healing.

December 28th, 1907.—The ulceration of the left lower lid has now almost healed, and the infiltration of the parts is much less marked. The other lesions are also doing well.

**Remarks by Dr. David Walsh.**

There is a good deal yet to learn about the iodide-eruptions. In the foregoing case the original papule so exactly simulated a gumma that on clinical appearances alone anyone would naturally have diagnosed that condition. A similar neoplastic growth, however, is seen in the bromide papules met with sometimes in epileptic patients in whom there is no suspicion of syphilis. There is much similarity between the bromide and the iodide lesions—they are of rapid growth, are practically confined to the face and tend to early ulceration, while they are both serious conditions and sometimes end fatally. Another interesting fact is that both are caused not infrequently by the use of patent medicines: the one containing iodide and sold in the guise of "blood purifiers," and the other, bromide, entering into the composition of many nostrums sold for the "cure" of fits.

It is an old observation that both iodine and bromine are found actually present in the lesions. Many years ago it was suggested that their presence was due to the excretion or attempted excretion of the irritant metal concerned. In any case it may be reasonably assumed that the irritation forms the starting point of the nodule. How it comes to be deposited in one particular spot is an interesting speculation. Where the lesion originates in an excreting gland it seems likely that there may be a direct excretory irritation of the gland with secondary periglandular inflammation and invasion by pyogenic organisms. In one case of iodism under my notice there was cardiac trouble and feeble circulation, conditions that seemed to me likely to favour local deposition of the irritant.

So far as I remember a weak pulse is invariably associated with iodism, a fact that is compatible with the depressant action of the iodides on the heart.

The recurrence of iodism and bromism is an interesting point. During a continuous administration of either drug it is not unusual to meet with recurrent attacks of dermatitis. The mere fact of accumulation in the body is thereby practically excluded—as a matter of fact, some persons give larger doses of the iodide in order to cure the associated drug dermatitis. The likely explanation seems to me that the iodism is usually a phenomenon of weakened circulation and its first effects are seen in or near cutaneous glands, where the local circulation is likely to feel the first effects of a less forcible bloodstream. At any rate the relation of bromism and iodism to circulatory conditions would form an interesting and possibly fruitful subject of investigation.

At a recent meeting of the New London Dermatological Society a case of mixed bromide and arsenic eruptions was shown by Dr. Samuels. The patient was an epileptic who had taken bro-

**Fig. 1.—Case of Tubercular Iodism Simulating Gumma of Eyelid.**

January 15th, 1908.—The ulceration of the lower lid has healed. But there still remains some reddening and thickening of the outer half or two-thirds, with a few scales of desquamating skin at the lower part of the thickened area.

**Remarks.**

Of the various skin lesions that may on occasion follow the internal administration of potassium iodide, that described in the present communication is probably the rarest. At one stage the resemblance to gumma was most misleading. I was not surprised accordingly to find the following remarks made upon the subject in the fourth edition of Dr. Norman Walker’s "Introduction to Dermatology" (p. 60).

"In rare cases the lesions produced are at first solid, and later break down in a manner so similar to the gumma, that one or two patients have been dosed into their graves by the pushing of the very drug which was the original cause of their trouble. In others, large solid tumours have developed, leading to the mistaken diagnosis of malignant disease or even leprosy."

In reference to the present case a couple of points appear to be worthy of notice.—First, that the potassium iodide had been discontinued eighteen days before the patient was first seen by me; and, secondly, that the several lesions healed under the administration of another iodine compound, namely sajodin.
mide of potassium for years. There was a bromide papule on the cheek and smaller lesions on the eyelids which reminded one both in site and general appearance of Mr. Sidney Stephenson's case.

My own view is that neither the bromides nor the iodides should be given continuously in any case. Both are potent drugs, and there is abundant experimental evidence on record of their effect on the kidneys and other organs of the lower animals. In spite of obvious warnings of the kind we most of us continue to introduce for indefinite periods into the bodies of our patients drugs which exert a powerful irritating effect upon vital internal organs. It has always seemed to me that some part, at any rate, of organic disease of obscure origin may be due to our well-mean, but ill-regulated, therapeutic efforts.

So far as the ill effects of the iodide papules are concerned they are probably almost entirely toxic, due to the development of secondary pyogenic organisms in the lesions. These organisms are probably in many cases staphylococcic in their nature. The indications for treatment are simple. First, to cut off the drug absolutely; secondly, to give the patient rest, cardiac tonics, and to flush the kidneys with water or demulcent drinks; thirdly, to treat the iodide papules as specific pathogenic infections rather than as a mere drug eruption, by local antiseptic measures and by attempting to immunise the blood with vaccines, preferably autogenous.

CO-ORDINATION IN ADMINISTRATIVE METHODS IN DEALING WITH INFECTION AND INFANTILE MORBIDITY. (a)

By G. CLARK TROTTER, M.D., C.B., D.P.H., Medical Officer of Health and Tuberculosis Officer, Paisley.

In bringing before you for discussion the question of how far our administrative methods in the several and still increasing ramifications of the public health service can be co-ordinated so as to secure concentration of effort and efficiency, I was prompted by the fact that to some extent at least our office is modelled upon any part of other towns. This being so, the subject thus lends itself to comparative criticism; it must be remembered, however, that the area and population of Paisley are such that supervision is possible by one officer, and that if the town were larger further division of labour might be necessary as regards some of the work which is now combined.

It must long have been the opinion of Medical Officers of Health—In connection with infectious cases dealt with, both as regards results and the amount of expenditure involved—that, judged by a commercial standard of value in return for the amount spent, inequalities predominated. To a considerable extent hospital treatment has come to be looked upon as the case of the compulsorily notifiable infections, as an arrangement to suit the convenience of the citizens. This has come about by the well-meaned pressure which was brought to bear upon the householder—at the time the Infectious Diseases (Notification) Act became law—with the object of having cases removed to hospital. Now, undoubtedly this procedure was wise, as the diseases small-pox, enteric, and 1 believe also diphtheria from the nature of the infection are best dealt with in hospitals, but along with these others as scarlet fever were placed in the same category. The result has been that practically all these compulsorily notifiable diseases are treated in hospital. The cost of scarlet fever cases is the cause of a large annual expenditure, for which little can be shown from the point of view of prevention, and the disease is less fatal than measles or whooping-cough, which do not get anything like the same attention.

Now by better co-ordination of our administrative methods much might be accomplished. In the past there has been too little differentiation in the methods of dealing with infections, they have been grouped broadly as communicable or non- communicable; looked upon, might I say, somewhat as compulsorily to receive attention involving expense in the first class, and but little in the second. The way has been opened as it were, within the last few years, for an alteration in our administrative methods, instead of a universal label "infectious" to all notifiable diseases, much more attention is being directed to considering each disease strictly according to the precautions that can be taken. The Public Health (Scotland) Act of 1867 was amended in 1907, instead of the words "free from disease and infection" the words "proper precautions against spreading disease and to prevent its being communicated" were substituted; the definitions sections 57, 58 and 59 dealing with prevention of infection. While the idea was to obviate harshness in cases of phthisis, adoption of notification of which was then being urged, the change effected is not limited in its application, inasmuch as the "proper precautions" to be taken vary according to the disease, and with the advance of our knowledge of particular infections.

With the object of gaining information as to the working of several units of the public health service in connection with infection and infantile mortality—in ways different from the usual routine—I made inquiries of the Medical Officers of several boroughs. I find that the changes effected have been mainly with the view of dealing with scarlet fever cases, and although the object of this paper is not to discuss the merits or otherwise of any particular treatment, the fact of such radical change being brought about and sanction being granted by the Local Government Board, who permit dispensary or hospital treatment, while not insisting on a particular treatment, the fact that the Officers have to be insisted on, makes it necessary for me to review briefly the information gleaned, as it has a bearing both on the question of co-ordination between home visitation and hospital treatment, and in a general way on the whole administration, as it shows how advantage can be taken of the modification of the Act.

The burghs of Forfar, Clydebank, and Barrhead have for some time been treating cases of scarlet fever at home. In 1913 in Forfar 91 cases were treated in hospital, and 270 at home; in Clydebank 76 cases were treated in hospital, and 52 at home; while in Barrhead 3 cases in hospital, and 21 at home. The treatment is carried on as follows:

1. The burghs of Forfar and Clydebank have two special staffs of hospital, and Barrhead the medical practitioner in attendance is paid £1 per case, and the mother of the child is provided with a thorough basket and cloth to rub the child, and eucalyptus oil for rubbing. In the last-mentioned burghs scarlet fever is treated by Dr. Miller, in the first two burhgs a special nurse is employed to carry it out, but in Barrhead the medical practitioner in attendance is paid £1 per case, and the mother of the child is provided with a thorough basket and cloth to rub the child, and eucalyptus oil for rubbing. In the last-mentioned burghs scarlet fever is treated by Dr. Miller, in the first two burhgs a special nurse is employed to carry it out, but in Barrhead the medical practitioner in attendance is paid £1 per case, and the mother of the child is provided with a thorough basket and cloth to rub the child, and eucalyptus oil for rubbing. In the last-mentioned burghs scarlet fever is treated by Dr. Miller, in the first two burhgs a special nurse is employed to carry it out, but in Barrhead the medical practitioner in attendance is paid £1 per case, and the mother of the child is provided with a thorough basket and cloth to rub the child, and eucalyptus oil for rubbing.

(a) Paper read at the Royal Institute of Public Health, Edinburgh, Congress, July 20th, 1914.
overlooked, and is bound to be commented on when neighbour towns are adhering to hospital treat-ment. The appeal to the Local Government Board under Section 56, Sub-section (1) (d) of the Public Health (Scotland) Act, 1897, in the case of Barrhead, was given on condition that the medical practitioners were left free to prescribe and administer whatever treatment they consider most appropriate to the case, and it was distinctly stated that approval could not be given to " Milbe, or any other particular form of treatment. In Paisley practically all the cases of scarlet fever are treated in hospital. There were only three cases at home last year, so as regards home treatment of this disease, I have no comparisons to offer. The information I have given has, therefore, been got from towns where hospital treatment is in vogue. I have sometimes thought it is frequently a blessing in disguise for some children to have a mild attack of scarlet fever; after five or six weeks in our Borough Hospital the change in their general health and condition is so very marked, they are, as it were, physically recuperated and set up for some time at least. Measles, whooping-cough, chicken-pox, and mumps cases are visited, a special nurse being requisitioned from our hospital for this purpose, the cases mostly being notified through the schools. The Local Authority does not, as in the case of certain other infectious diseases, generally (that is, in the course of the year) provide for hospital treatment of measles and whooping-cough, but when it is obvious from the home conditions that the child has not a reasonable chance of being properly treated, it is left to the discretion of the Medical Officer of Health to admit the case to hospital. In 1913 the measles cases recorded were 1,497, whooping-cough 454, chicken-pox 525, and mumps 827. Sixty-five cases of measles were treated in hospital.

But with regard to methods of dealing with infantile mortality, as the result of the inquiries I have mentioned, I have not found that any town is working on exactly similar lines, for we have in connection with our Municipal Dispensary, which is specially for tuberculosis, observation beds, and on the principle that "diarrhoea" and "wasting" might in infants and children be possibly due to tuberculosis, these cases are admitted for observation, and, with but few exceptions, are found to be the result of improper feeding. I believe that in medical treatment was tried, and that such cases discovered on visitation into various institutions for treatment, but this was not continued, the results not justifying the expenditure, but then the conditions are different there, and the experience not comparable, as all are not under one control. Last year in Paisley we admitted twenty-seven such children suffering from diarrhoea, malnutrition, etc., nineteen were dismissed well, six considerably improved, while there were two deaths. This year the experiment has been continued, and a larger number, for the time dealt with, about twenty having been treated. My opinion is that in a proportion of the cases which come under the observation of the health visitor, this is the only feasible method that has any chance of success. It is quite useless, as is done at some dispensary consultations, to give, say, a powder, with directions regarding diet, to the mother; the child is by the time advice is sought in such condition that nothing short of removal for a time from its environment, together with adequate treatment, is, I think, necessary, and this, if not, will be of no avail. After dismissed the visits of the health visitor to the home will in many cases require to be continued to ensure proper attention being paid by the mother.

Now to summarise the co-ordination which might be recommended. The Medical Officer of Health must necessarily be in close touch through the visiting inspector, nurse, or nurses, with all the cases—infected, tuberculous, or infantile (visited under the Notification of Births Act); in a country district probably notification deaths can be performed by one person. Where domiciliary treatment has not received approval of the Local Government Board, this might be obtained on board lines, as in the case of the Burgh of Barrhead, for even if not used as a routine, it in times of epidemics may prove a useful asset.

The dispensary, and these now are largely in use for treatment of tuberculosis, could freely be used as advice centres, not for that disease alone, but for such cases as fail to get medical attention. There is no definition to limit the term "infectious disease" of the Public Health Act to compulsorily notifiable cases—the term may embrace pneumonia, syphilis, diarrhoea, etc.—in fact, to a very large extent the recommendations of the Minority Report on the Poor Law could practically be acted upon and treatment provided with the object of lessening mortality, which next to prevention of disease is the aim of our public health administration.

THE STATE IN RELATION TO THE PROMOTION OF MEDICAL RESEARCH. (a)

By SHERIDAN DELEPINE, M.B., C.M., M.Sc.,
Professor of Public Health and Bacteriology, and Director of
Public Health Laboratories, University of Manchester.

Up to quite recently most of the benefits which the State has derived from the scientific work done in this kingdom have been conferred upon it by means of private means or receiving grants from private persons, associations, or societies, etc. Most of these grants were intended to meet experimental expenses, and their recipients, except those with private resources, had to earn their livelihood by the exercise of a profession which very rapidly claimed the best part of their energies.

The successful cultivation of pathology and preventive medicine—that is, of the study of the causes, effects, and prevention of disease, generally demands a considerable expenditure of time and of money, and the co-operation of many trained observers is often essential to success. Up to about thirty years ago no special provision had been made for this kind of study. What had been accomplished before then was the outcome of the efforts of enthusiastic clinicians and young morbid anatomists awaiting promotion to some clinical post in various hospitals. There existed a few chairs of pathology, but these were associated with heavy clinical duties. There was no endowment applicable to pathological research. The first chair of pure pathology was that created in Aberdeen in 1882; the Cambridge chair dates from 1884. The State has, therefore, been far behind other educational institutions, and since then that science has been recognised as a subject deserving a full chair by all modern British universities.

During the same period the public health service, as we understand it at present, became organised for the first time. It may therefore be said without exaggeration that the arrangements made for the systematic study of the causes and prevention of disease are still in their infancy. The new universities, which owe their existence to the liberality and foresight of enlightened citizens of some of the great provincial towns, have of late

(a) Presidential Address before Section of Sanitary Science and Preventive Medicine, Congress of Royal Sanitary Institute, Blackpool, July, 1914.
received Government grants, which have gradually become more and more substantial, but these grants have been chiefly for teaching purposes.

Some important research institutes, such as the Lister Institute, the Usher Institute, and the Thompson Yates Laboratories, have been endowed by private benefactors since 1891. The College of Physicians in London and Edinburgh had not long before created research laboratories. A partly self-supporting public health laboratory was established in 1892 in Manchester. More recently, funds, such as the Cancer Research Fund, have been raised for special purposes. These are indications of the efforts which have been made during the past twenty-five years towards the improvement of higher education and of research facilities, but with all that, the number of desirable posts open to those who wish to devote themselves to a career of scientific research are still very few, and also prospects offered to those who would spend a few years in research are not encouraging.

The creation of chairs of pathology and allied subjects might have given greater opportunities for research had not the teaching and other duties connected with many of these posts been so heavy, and the funds available for research so small.

There has, however, been a gradual improvement during the past fifteen years in these respects, and hospitals are now in the United Kingdom between fifteen and twenty centres where the amount and importance of research work could be considerably increased if funds were available for meeting the cost of experimental work, and for giving to research workers adequate compensation for the time spent in investigations, from which they can expect no other material reward. Even then further improvements would still be needed to place the relation of scientific laboratories with certain Departments of State, local authorities, and hospitals, on a footing more favourable to efficient co-operation than it is at present. It would also be necessary that research laboratories should not be under the control of governing bodies, can often be influenced by the clamours of popular craze-mongers meddling with things which are beyond their understanding or asking for the abolition of imaginary abuses.

Much of what I have said about the position which the State has taken with regard to medical research in the past is true today. In the following quotation from the Final Report of the Departmental Committee on Tuberculosis, Vol. I., 1913, p. 13, which at the same time gives hope for better things in the future:

"It is, however, generally known that two widely different policies are possible—viz., one of complete centralisation, and one of devolution combined with limited centralisation. As the scheme finally adopted may prove to be of considerable importance in the future development of preventive medicine and public health, it appears to me desirable that the matter should receive the careful consideration of all who are interested in the public health service. The advisory council and the executive committee consist of persons belonging to State departments, institutions, and associations interested in the prophylaxis of disease, and some of the members have been actually engaged in research. These members cannot be said to represent the bodies to which they belong, because they have not been elected by them. It is, therefore, most desirable that those who are interested in the matter and in a position to form an opinion should now be known the views which they hold, as this may prove of assistance to the advisory council when the time arrives for them to come to a decision.

With the object of stimulating criticism I propose now to show how, in my opinion, a policy of complete centralisation would affect medical research. In the first instance I wish it to be clearly understood that whatever combined centralisation and devolution applies only to the actual work of research, and that, whatever method was adopted to carry out that work, some general guidance would be needed to indicate the nature of the investigations, to co-ordinate the work done by various investigators, and to utilise its results so as to meet the requirements of the State. This being understood, I will now consider a scheme for complete centralisation.

The Government would, in all probability, appoint a committee consisting of a director of research and several officers closely connected with those departments of State, such as the Local Government Board, the Home Office, etc., which must consider whether the local authorities and the new research laboratories would be erected, or some existing ones taken over. There would be in this central laboratory several sections, each of which would be under the special direction of a man able to take charge of some special branch of science, and to direct younger investigators. This man would be connected with an existing hospital, or some new special hospital might be associated with it. past, and their opinion that research under the National Insurance Act should be organised in such a way as not to discourage either voluntary contributions or voluntary research towards the same ends. The aim should rather be to stimulate and co-operate with voluntary agencies."
phalanx of young workers in a new laboratory. These young adults would not be respected by time any more than their senior colleagues have been, and in order to obviate the age difficulty it would be necessary to provide for frequent changes in the staff of the central laboratory. The central laboratory must be so arranged that it is capable of conducting a large number of experiments under the supervision of the superintendent, and for covering experimental and other current expenses. The stipends offered to the directors and other research workers would probably be sufficient to induce some of the best investigators to come to this central institution.

Valuable experimental work could be done under these conditions; but as the problems with which public health is concerned are in many cases greatly influenced by local, social and other conditions which vary considerably in various parts of the kingdom, certain investigations would necessitate the appointment of persons whose duties it would be to conduct researches in suitable localities. Certain researches, however, occupy many years and sometimes a lifetime. This is particularly true of statistical and of certain clinical and aetiological investigations. Some of the data necessary for such investigations have been in the past collected with great care and accuracy in some centres, at health offices, hospitals and other institutions, while the information available is less complete and reliable.

The investigators sent by the central committee would, therefore, require to have access to the books and other documents kept at various hospitals, health offices, etc., in order to be able to carry out their researches. In this way the central laboratory could control provincial work through a new agency, and its dependence on existing local agencies, though in many cases dependent on local institutions and men for most important data.

I hardly need to enter into more details in order to make clear some of the objections which can be offered to complete centralisation of medical research. The most important laboratories or the adaptation of old buildings would mean a material expenditure on buildings at a time when, both in London and all through the country, too much expenditure has already been incurred for the same purpose, and when money is wanted chiefly for workers and working expenses. If the provision of central laboratories for research and the offer of emoluments better than those obtainable in existing laboratories caused a migration of the best workers to some central institution, this would deprive existing institutions of the stimulating influence of these men.

It is doubtful whether this bringing of research workers together to one centre would result in greater efficiency than could be secured by supplying the same workers with the necessary assistance and subsisities without displacing them.

If, on the other hand, the policy adopted was to select research workers from among the ranks of the untired younger generations, the difficulties which impair the efficiency of existing centres would not be remedied and the action of the Government would be conversion of a speculative venture. It is difficult to believe that a small Government committee would, even if composed of men of exceptional foresight, be more successful in discovering budding geniuses than the senators and councils of all the universities of the kingdom put together have been in the past. It is true that at any time a certain proportion of the professorships, lectureships, and other posts giving opportunities for research are occupied by men no longer young and whose productive activities are possibly inferior to those of younger men, but this fault would not be remedied by the creation of a State department, laboratories and other institutions, which have up to the present been chiefly concerned with the study and control of disease and social conditions, might be followed by some immediate benefits; but much greater and more permanent good would be secured by helping, strengthening and co-ordinating the existing institutions, most of which are in great need of such help.

JUDGE SMYLY asked a doctor who was suing for his fees in the Shoreditch County Court what the patient had suffered from. The plaintiff claimed the medical privilege of not disclosing his patients' ailments, which the judge agreed with.
CLINICAL RECORDS.

AN INTERESTING CASE.
By HENRY CARSON SMYTH, L.R.C.P. and S.I.,
Resident Surgeon, Dr. Steevens' Hospital, Dublin.

WILLIAM D. was brought by the City ambulance to Dr. Steevens' Hospital, Dublin, on the afternoon of Sunday, June 5th, 1914, at five o'clock. He stated that he had been taken ill suddenly in the street with severe pain in the back, and vomiting.

The patient, a well-built man, aged 32, and unmarried, stated that he had always enjoyed excellent health, with the exception of some slight pain in his arms and hands about three months ago, for which he had to remain away from work for two or three days.

On the day of his admission to hospital, feeling quite well after eating his dinner, he had gone for a walk, and it was during the walk that he was seized with the pain and sickness.

He described the pain as starting in his back on the right side near the lower margin of the liver, and shooting towards the opposite side, and up to the right shoulder.

On admission the patient was evidently in severe pain, his face was flushed, and the right side of his neck was oedematous, his temperature was 106.4 F., pulse 88, and respirations 24 to the minute.

On examination no abnormality was discovered in the heart, lungs, or abdomen, and the urine did not contain either sugar or albumin.

Shortly after admission the oedema extended to the right side of the face, and an hour later to the left side of face and neck, closing both eyes. The pain was still severe, and had become constant, but of no relation to respiration movements. The pulse rate increased to 100, but the frequency of respiration was the same as before.

At eight o'clock p.m. the patient was restless, had some dyspnoea, but was able to lie down on his left side. The pulse rate had increased to 110 and respirations to 28 per minute. By midnight the pulse had further increased to 130 and the respirations to 40 per minute. The patient was suffering from marked dyspnoea, and he stated that the pain was rather worse than it had been before.

On examination of the chest at this time distinct surgical emphysema was found over the right side, and there was marked loss of resonant sound over the border of the left side of the wind-breath sounds. The oedema of the face had diminished, and patient was able to open both eyes. At 4 a.m. the pulse rate had fallen to 128, but the respirations remained at 40, and the dyspnoea had increased. Patient otherwise seemed easier, and stated that the pain was better. At 7.30 a.m. the patient had a violent attack ofretching, and brought up a small quantity of blood-stained fluid. He then became deeply cyanosed and died almost immediately.

Post-mortem examination twelve hours after death:

There was slight oedema of the neck and face, and the abdomen was distended. On opening the chest both pleural cavities were found to contain fluid under considerable pressure. This fluid was dark and blood-stained, and resembled that which the patient had vomited immediately before his death. Both lungs were collapsed, but did not appear to be diseased. The pleura itself and the pericardium were not inflamed, and the heart was normal. The mediastinum was occupied by what appeared to be a large cyst, the walls of which were adherent to the oesophagus behind and to the posterior surfaces of the pericardium and lungs in the front. The cavity of the cyst contained fluid similar to that in the pleural cavities, and the walls were necrotic. There was a small opening about half an inch in length from the cyst into the oesophagus, just above the diaphragm, and there was also a communication with both pleural cavities. The stomach was distended and contained fluid similar to that found in the chest. The other organs appeared healthy. Careful investigation failed to reveal the origin of the cyst, and no sign of an abscess or of pus was found.

OPERATING THEATRES.

THE CHILDREN'S HOSPITAL, GREAT ORMOND STREET.

A CASE OF ECTOPIA VESICE.—Mr. ERED M. CORNER operated upon a girl of about 5 years of age, the subject of ectopia vesice. Both the urethra and the bladder were completely everted, exposing the ureters and the trigone. The urine was led away from the bladder by means of two catheters, and that of the ureters was carried in four inches apart. The openings of the ureters were demonstrated by means of passing a catheter up each of them, and allowing the urine to flow through the catheter. Each catheter was then fastened in by silk and passed through the mucous membrane of the bladder. Mr. Corner referred at some length to the very unsatisfactory results which were obtained by means of covering in the exposed bladder by flaps. He preferred to take the greater risk and to make that flap wide and straight into the sigmoid flexure. It was objected to this method that the kidneys were infected from the bowel, and the patient died of uremia. But it could be replied that such persons on whom the transplantation had been successfully made led much more useful and enjoyable lives; some did not die young of uremia, and it had been asserted that ureteral transplantation with the trigone prevented, or tended to prevent, the passage of organisms from the bowel to the kidneys. The operation was proceeded with. All mucous membrane round the trigone was cut away and the abdomen opened. An assistant inserted a gloved finger into the rectum and made the sigmoid present at the wound. Having freed this part of the operation, it became apparent that the better and more useful and enjoyable lives; some did not die young of uremia, and it had been asserted that ureteral transplantation with the trigone prevented, or tended to prevent, the passage of organisms from the bowel to the kidneys. The operation was proceeded with. All mucous membrane round the trigone was cut away and the abdomen opened. An assistant inserted a gloved finger into the rectum and made the sigmoid present at the wound. Having freed this part of the operation, it became apparent that the bladder could be turned round easily, the sigmoid was opened, and an anastomosis made between the inverted trigone and the sigmoid. Mr. Corner here stated that he had split the trigone and made a small incision in the bladder. It was the difficulty of inverting the whole trigone, but was not so satisfactory. The inverted trigone tended to evert, and it was desirable to put an extra row of stitches at the upper part of the anastomosis to prevent this. When the anastomosis was completed a large hole remained in the abdominal wall. This had to be closed, and it required some ingenuity to accomplish it. In more than one case the hollow vaginal wall had been used to help fill up the gap. The difficulty was due to the cleft pubis. The operation had already been long enough, and to close the pelvis meant opening up each sacro-iliac joint as a preliminary, an operation involving much shock and quite out of the question. Mr. Corner stated that after operation these children's bowels were opened four or six times a day. They were a kind of autopenia. He intended closing the cleft pelvis by another operation a little later on. He should make no recommendation without due consideration. It was quite usual for a little leakage of urine to take place at the end of a week, making a daily dressing advisable. The critical time as to the success of the operation was during the period of the haemorrhage. It was then that the anastomosis stitches might loosen and the trigone begin to evert. If this happened the amount of urine escaping increased, and finally a ureretic opening could be seen. Operations seldom failed so badly as to deserve two.
panned by acute pain. The history given was that eighteen months previously she had been operated upon in another hospital for what was thought to be an appendix abscess. To was evacuated, but later on urine escaped from the wound. After a time, however, the wound healed. She remained fairly well until two months ago, when she got sharp pains across her back, and these gradually got worse until eight days ago, when they became located in the right lumbar region, shooting down into the groin. On examination, a tender swelling was found in the right iliac-lumbar region. The healed scar of the child incision, situated two inches above and to the inner side of the anterior superior spine of the ilium. An X-ray photograph showed no stone. The patient suffered from chronic constipation. A small incision was made in the right loin and a trochar and cannula inserted, a large amount of pus and urine escaped, and the opening was enlarged, the finger entering a large pyonephrotic cavity. After a careful search a small stone was found and removed from the lower portion of the pelvis of the kidney. A drainage tube was inserted. Next day the tumour had disappeared, there was an increase in the amount of urine passed, and it contained blood. The wound gradually closed and the patient made an excellent recovery.

Nephrectomy for an Old-Standing Sinus of the Right Kidney.—Sarah B., aged 14, was admitted suffering from a sinus which had been discharging from the right lumbar region for a long time. The history given was that the child was healthy until four years previously, when she began to have attacks of pain in the right side. These were often of a severe nature, but in the intervals the child seemed quite well. A year later a lump was noticed in the right side and the pain became constant and severe. An operation was performed in one of the Liverpool hospitals, and this was followed by a second and then by a third. At the last operation a stone was said to have been removed; the wound never closed. On examination there was a sinus discharging pus and urine in the right loin with some tendingness on pressure. An X-ray examination showed no stone. Under ether Mr. Newbottle passed a probe down the sinus; it entered a large cavity, so the sinus was laid freely open. The walls of the cavity were formed of a thin layer of kidney substance, and after a tedious dissection the whole of the sac was dissected out, the renal vessels were tied, and a small portion of tissue lying on the vena cava scraped. No stone was discovered. A large drainage tube was placed in the cavity, and thus wound healed firmly, the child making a good recovery.

Mr. Newbottle said these were two cases of interest. The first was a case of calculus pyonephrosis, and was rather unusual as that recovery had ensued when apparently the kidney had become disorganised. Again the X-ray examination had failed to show the stone, probably because the swelling was very large and it was difficult to exert any pressure when taking the picture. In the second case the child had been an invalid for four years, and the kidney was almost totally destroyed. The cause of the condition was probably the same as in the first instance, but even though there had been removed the kidney did not recover as might have been expected in a child. The operation was extremely difficult, as the parts were adherent to important structures.

TRANSACTIONS OF SOCIETIES.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

Meeting held Thursday, July 6th, 1914.

The President, Dr. David Walsh, in the Chair.

The President showed a case clinically resembling tertiary syphilis, but in which the Wassermann reaction was negative. The patient was a woman, aged 50, who had been under treatment on and off for the last nine years for an eruption on the leg. She had had eight children, of whom seven are living, and has had no miscarriages. The general health is good, but she has rheumatic pains at times and suffers from diffuse headache. About the legs there is a ringed eruption of somewhat peculiar appearance; there is an oval raised verrucose area, surrounded with a whitish cicatrical area, and that again by a red margin. The verrucose is on the right leg, but lately the eruption is generally distributed, and several patches are on the left leg and ankle. Clinically the case suggests a tertiary syphilis, but a Wassermann test proved negative. The patient had not taken any mercury for some weeks before the blood was tested. Dr. Walsh said he had seen verrucose plaques showing these, and the case was probably of that nature.

Dr. D. Vinnace said that if this had been lichen hypertrophicus, he believed there would have been a lichen planus and probably would have been lichen plants elsewhere on the body.

The President exhibited a photograph of a patient with multiple hard changes. The patient had some desultory treatment, but was of careless habits, and he had no less than seven hard changes. He had not previously seen, nor found mentioned in literature, a case with so many hard sores. Six were on the penis, and one was among the pubic hair. Probably the sore on the woman was on the upper part of the penis. At the first operation Dr. Walsh took off one of the lesions with a little cotton wool, and in the scar which afterward exuded spirochete could be seen. They healed up marvellously under neo- varsyn, and the patient appeared to have had no fresh cutaneous lesions.

Dr. Vinnace said he assumed that most members had seen cases with two changes at the same time. He had one case now under treatment by "606"; one case of tertiary syphilis and lichen. The other was the patient. He had a patient with three changes concurrently.

Dr. II. C. Samuel showed (1) a case of drug eruption. The patient, a youth, had an extensive eruption. The patient was given arsenical hyperkeratosis and some lesions on the conjunctiva. This was the second time he had had a drug eruption. The previous attack was an ordinary bromide arm.

Dr. J. Midleton asked whether Dr. Samuel was prepared with any explanation of why these rashes formed at all. They were largely pustular, and one wondered how the peculiar organisms gained entrance to the lesions. He had heard that by giving one of the inorganic salt solutions and the diapedesis of leucocytes, and so there was activity around the area spot, for instance. One writer had spoken of the intensive administration of iodide of potassium followed by chloride water; and another spoke of powerful irritation of iodine, four times as strong as the usual. He would like to know whether this patient had had less eruption since the eruption occurred. He regarded epilepsy as a toxic ailment, and in this patient an outstanding factor was tooth sepsis. He objected to giving bromide of potassium as a remedy for epilepsy. In all cases bad teeth should be extracted; it had known cases get well simply after that had been done.

Dr. G. Trivick said that general practitioners looked upon bromide as the sheet-anchor in cases of epilepsy; and he had had cases in which the fits were kept in abeyance and the patient was more comfortable taking bromide. But he agreed with Dr. Midleton that cases should be observed with the view of detecting any source of irritation, such as errors of refraction or, conditions of the nose or throat. But even then there was a residue of cases in which nothing could be done. He always remembered the case of a medical man who, under the impression he had rheumatism, took iodide continuously. Finally, he called in a consultant, who found him to be suffering from acute nephritis, from which he had never recovered.
Dr. VINRACE said he understood that this bromide rash had only existed for days; and he would like to know the date when the signs of arsenic poisoning occurred, also what were the manifestations in this case. Had the exhibitor any explanation of the multiple scars and pustules which appeared on epileptics treated with bromide. In the present case the Ophthalmoscope appeared a beautiful coloured plate of a case of his own, which, because of the eye condition, came under Dr. Sydney Stephen's care. In the case of iodide papule the patient had an ulcerating tumid lesion on the cheek, one on the eyelid, much resembling that in Dr. Samuel's case, except that one was due to bromide and the other to iodide. Clinically, it would be difficult to distinguish the lesions due to the two drugs. Iodide papules were very rare; and where they appeared the patient probably had some idiosyncrasy. Sometimes the iodide was increased in dose with the idea of getting rid of the papule. He had seen many patients who had responded in that way. His own case was syphilitic, and the iodide papule followed traumatism in the eye. It was well known that gumma did follow injuries. He asked what Dr. Samuel possessed as a cure for his present patient seemed to be in a serious condition. It seemed to be a case of having to choose between bromide and epilepsy. This patient had been taking bromide for a long period; why should the drug at one particular period do so much damage to the kidneys at such times rebel and refuse to excrete the drug, so that it was driven to choose another means of exit? The danger from giving bromide consisted in its continuous administration. The same was true of syphilis; patients were given the drugs in hospital for six, nine, and twelve months without interruption. He contended that the administration should always be interrupted.

Dr. SAMUEL replied that in making statements one was often guided by instinct. When the patient first came, there was what appeared like a streptococcic condition; there were some attacks, where one would have expected the streptococcus to grow; and there were outlying inflamed hair follicles, such as were found in intertriginous conditions. Moreover, the swelling and the recurrent feature favoured the streptococcic view. He admitted that in many of these cases went on to erythematous eczema, not erysipelas; they had no constitutional symptoms.

**SPECIAL REPORTS.**

**THE EIGHTY SECOND ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION HELD AT ABERDEEN, 1914.**

[By Our Special Representative.]

Sixteen years have elapsed since the British Medical Association met for its annual meeting in a centre north of the Tweed. It was in 1898 that the city of Edinburgh played the part of host, and now for the first time in the career of the Association the "Silver City by the Sea," as Aberdeen has been styled, is acting this week as host to many hundreds of members and their wives. The historical associations of Aberdeen are great and interesting in the extreme, and the Association is fortunate indeed in being able to house the whole of the Sections, as well as the Exhibition, in the spacious and magnificent Marischal College. A splendid welcome has been extended by the citizens and medical fraternity of this "grey, wintry-featured, sea-tempered" city of the North to all the visitors by whom she is at present thronged.

Sir Alexander Ogston, K.C.V.O., L.L.D., M.D., the newly-elected President of the Association, is well known to the members of the Association, and has the good wishes of H.M. the King in Scotland, and Emeritus Regius Professor of Surgery in the University of Aberdeen. Born in 1844, he was educated at Aberdeen University.
qualifying as M.B., C.M. in 1865, becoming M.D. in the following year. His valuable services connected with the Royal Infirmary are remembered with lasting gratitude, and he is now Consulting Surgeon thereto. In 1885 Sir Alexander (then Professor Ogston) served in the Soudan, and in 1896, 1900 in the South African Campaign. His Address on Surgery, delivered at the Portsmouth meeting of the Association in 1896, on "The Medical Services of the Army and Navy"

SIR ALEXANDER OGSTON, K.C.V.O.

created a great impression at the time, calling attention, as it did, to various shortcomings that then marred the medical efficiency of the two great Services. Such fearless criticism, an ardent desire to seek the truth, and an undaunted courage in the face of obstacles are among the characteristics of Sir Alexander Ogston, who is held in the highest possible esteem by the citizens of Aberdeen. He was appointed Surgeon-in-Ordinary by the late Queen Victoria and also by King Edward VII. In 1912 he was created K.C.V.O. The University of Glasgow bestowed upon him the Hon. L.L.D. in 1907, and the University of Aberdeen followed suit in 1910. Sir Alexander is a Deputy Lieutenant for the County of Aberdeen, and also Hon. Colonel (R.A.M.C.) Highland Territorial Division.

Such is the record of a distinguished surgeon who now presides over the fortunes and future of the British Medical Association for the ensuing year, and the Association may indeed be congratulated upon its choice.

GENERAL ARRANGEMENTS.

It is fitting that the Association should meet in Scotland this year now that it has been decided to establish a permanent Scottish office with a whole time Scottish Medical Secretary.

The momentous decision has been arrived at, after the liveliest discussion and the expression of many divergent opinions, that the special fund for the defence of professional interests should be in the hands of a Trust Association, or other organisation, not a Trade Union.

Before the President's Address was delivered, Sir Clifford Allbutt, K.C.B., the President Elect for the Cambridge Meeting, 1915, was introduced.

The President delivered his address last night before a crowded and distinguished audience.

At 11.30 p.m. on Monday the Address on Medicine will be delivered by Dr. Archibald Edward Garrod, M.D., F.R.C.P., F.R.S., Physician to St. Bartholomew's Hospital, while, at the same hour to-morrow, Sir John Bland Sutton, Surgeon to the Middlesex Hospital, will deliver the Address in Surgery.

RELIGIOUS SERVICES.

At 9 a.m. this morning the annual service for the Association will be held in the West Parish Church of St. Nicholas (Church of Scotland). A service for Catholic members will be held simultaneously in St. Mary's Cathedral, Huntly Street, when it is hoped that the Celebrant will be the venerable and revered Dr. Chisholm, the Bishop of Aberdeen, the sermon being preached by the Rt. Rev. Mgr. Meany, the Administrator of the Cathedral. At both services coin will be made for the Royal Medical Benevolent Fund.

THE WORK OF THE SECTIONS.

As in the previous year, the scientific work of the Association will be conducted in sixteen sections, all of which are comfortably accommodated in the buildings of Marischal College. Among the interesting discussions that are to take place are those on: "Headache" (Section of Medicine), to be opened by Dr. Harry Campbell; on "Death Certification" (Section of State Medicine), to be opened by Sir Victor Horsley; on "The Etiology and Treatment of Carcinoma of the Tongue" (Section of Surgery), to be introduced by Mr. W. G. Spencer. In the section of Electro-therapeutics an electro-cinematographic demonstration is to be given by Professor Bergonie. Certain combined discussions are sure to attract large audiences, such as that on "The Pharmacology and Therapeutics of the Animal Extracts exclusive of Thyroid Extract," to be opened by Professor Noel Paton (Physiologist) and Dr. O. F. F. Grunbaum (Therapeutics); and on "The Diagnosis of Chronic Pulmonary Tuberculosis in Infancy and Childhood," in which Dr. D. B. Lees, Dr. Clive Riviere (Section of Diseases of Children), and Dr. Ironside Bruce (Section of Radiology) will take part.

THE SOCIAL FUNCTIONS.

The annual dinner of the Association takes place to-morrow night, when a large gathering is expected. This afternoon the town Provost and Town Council of Aberdeen are giving a garden party in Duthie Park. Other garden parties are arranged for at the Deeside Hydro-pathic, which has a 9-hole approaching and putting course; at Parkhill House, near Don, at Inchmarnock, on the north bank of the Dee, and at other centres noted for their beautiful scenery. A number of long and short excursions to places of interest in the neighbourhood have been arranged for.

The Ulster Cup will be competed for at the Royal Aberdeen Golf Links, Balgownie, Bridge of Don, on Thursday, at 9 a.m. Intending competitors are requested to send in their names and addresses, along with their club handicap, to Dr. H. de M. Alexander, 29, King Street, Aberdeen. The comfort and convenience of lady visitors has been especially looked after, and altogether members and their ladies may be assured of a most pleasant and profitable visit.

THE ANNUAL EXHIBITION.

There is no excuse for members not visiting the annual exhibition this year, for this unique display of instruments, books, drugs, appliances and foods is housed under the same roof as the Sections. Being so conveniently situated, therefore, members will have an unrivalled opportunity of inspecting the various exhibits at their leisure. A few minutes spent in making a tour of the stands is time well spent.

ROYAL COMMISSION ON VENEREAL DISEASES.

SIR JOHN COLLIE, at the 48th meeting of the Commission gave the results of some observations he had
recently made in connection with 2,176 men referred to him for medical report. These were divided into three classes—(1) 1,119 whom accident or illness had overtaken, (2) 557 apparently healthy, but required to pass medical examination before entering employment, (3) 500 of the same class as the second division, but who also submitted themselves to the Wassermann test. Of all three division 196 were found to be suffering from venereal disease. In the first two divisions, in connection with which clinical evidence was relied upon, 60, or 6.2 per cent., were found to be affected, in the third class, where the Wassermann test was applied, 46, or 9.2 per cent., were shown to have had syphilis. The 500 cases of those apparently in perfect health (as evidenced by a thorough physical examination), which were taken as they presented themselves for examination, and no selection was made except that working-class people over 21 years of age only were chosen. 103 of the 500 had served in the Army or Navy, and of these 24, or 18.9 per cent., gave a positive Wassermann reaction. The percentage of positive reactions in the remainder of the 500 was only 6.

Sir John stated that the figures probably did not represent the full extent of the existence of the disease, for the men examined were of a somewhat superior artisan class. An interesting feature of the investigation was the fact that the Wassermann test showed a positive reaction in as many as 12, 16 and 19 years, and in one case as to 29 years after intimation, and in several after all recollection of the infection had disappeared.

Mr. Frederick J. McCann, F.R.C.S., Surgeon to the Samaritan Free Hospital for Women, said that it was of the utmost importance that syphilis and gonorrhoea should be regarded as common female ailments, for which no satisfactory treatment should be available as for other female ailments without any special stigma being attached to them. If proper facilities for in-patient and out-patient treatment were provided the special aspects of these diseases would to a large extent be obviated. He based his statement on the early local signs of syphilis and the signs and symptoms of gonorrhoea which were much required. This instruction should be given at the special hospitals for women and in the gynaecological departments of the general hospitals. He contended that it was essential that gonorrhoea should be regarded as a serious disease in both sexes, especially in women, and that prompt and effectual treatment was required. The medical profession would show its sense of the present aspect by impressing upon patients the gravity of the disease and the necessity for early curative treatment.

Dr. Chalmers, Medical Officer of Health for Glasgow, gave supplementary evidence at the 49th meeting of the Commission with reference to the experience of the Glasgow Corporation. He stated that ophthalmia neonatorum was made compulsorily notifible in Glasgow in 1911, and that in the beginning an attempt was made to supervise the cases at the homes. It was, however, soon apparent that this was far from being so effective for hospital treatment. Arrangements had accordingly been made for this treatment, and it had been necessary in some cases to provide also for the reception into hospital of the mother. Their experience had shown that a proportion of children suffering with ophthalmia neonatorum also suffered from congenital syphilis, and that the resultant defects in vision were greatest when the diseases were concurrent. In the period from 1911 to 1913, of 461 children suffering from ophthalmia neonatorum 13.6 per cent. were found also to be syphilitic.

Dr. Chalmers was of opinion that no form of compulsory notification of venereal disease, whether for any class of persons, or of cases, would effect its object. His view was that the trouble required not compulsion but education, and he presented to the issue of an authoritative statement showing the danger to life in after years of syphilis contracted at an earlier period, and of the disastrous effect on children would to a considerable extent effect this.
Painless Delivery.

The last meeting of the Académie de Médecine was particularly interesting by the communication of Prof. Ribemont-Dessaigne on painless confinement by the injection of a nerve sedative closely allied to mesothorium. A large number of women were thus treated in the maternal ward of the hospital, and each one seemed distinctly indifferent to the usual throes of delivery, absolute silence replacing crying. The uterus contracted on no way modified by the anaesthetic, nor was delivery retarded. As regards the child, it presented at first a kind of somnolence, but from which it was quickly aroused by holding it up by the feet and blowing into its little face. This treatment was ever observed in the mother or the child.

GERMANY.

Berlin, July 25th, 1914.

At the Medizinische Gesellschaft in Berlin, K. Klock discussed the Treatment of Malignant Tumours of the Eye by Mesothorium and Radium.

He said that very little had been recorded respecting such treatment. The reason for that was that metastases were feared and it had been considered safer generally to enucleate. The malignant tumours of the eye often presented a tendency to spread, which was accompanied by a special tendency to metastatic spread. The disease had been found in the liver as much as from 10 to 15 years after enucleation of the eye. He first showed two cases that had not been under treatment by radiation, one a large malignant tumour on the mesothorium, the other a sarcoma of the choroid. He would afterwards show them a series of cases that had undergone treatment by radium and mesothorium emanations. The first case was one of epibulbar melanoma of the right eye. The whole outer wall of the cornea was covered by a thick hardened skin that reached almost to the middle of the sclerotic. When the patient first came under treatment the disease had been in existence a year, and had been treated for that period by an ophthalmologist, chiefly by cauterisation. The vision in that eye was 5/10. The following was the course under irradiation: during the first months the sitting was for 30 minutes with 12 mg of mesothorium. There was diminution in the photophobia but not in the size of the growth. A total of irradiation was one hour and 35 minutes with radium, and 7 hours and 35 minutes with mesothorium. The papillary region was now quite clear and the thickened skin covering had disappeared. The pigment had partly gone and the conjunctival injection was much less. Almost the initial case of the growth had disappeared and a half hour later the tumour had receded still further. Clearing up was quite plain, the pigment in the upper part was quite gone, whilst that in the lower part was reduced to some slight patches. The tumour had now disappeared with the exception of a couple of small oval pigment spots the size of limpets.

The second case was one of melanoma of the right ciliary body. The patient, a woman aged 57, came to the clinic on account of loss of sight which she had been conscious of for six months. The iris was pushed forward and between it and the cornea was a brownish tumour. The result of irradiation by mesothorium for a total of 10 hours and 20 minutes was a diminution in the size of the tumour, and a considerable diminution of the internal pressure which had previously been high. The mesothorium was applied weekly for 30 minutes. At present the whole of the papillary region was quite free and the tumour was reduced to the size of half a pea.

The third case was one of epibulbar spindle-celled sarcoma in a woman of 39. The question was from an exploratory excision. For a month 10 mg of radium were applied every third day for 5 minutes. The growth the size of a bean was seated at the left external angle of the sclerotic and reached into the region of the pupil. The tumour, notwithstanding the treatment did not diminish in size, so that enucleation had to be performed. Within a month, however, there was recurrence which in spite of intensive radium treatment still persisted. It was then subjected to treatment by mesothorium for 50 minutes together; this gradually reduced the size of the growth so that the present height of the growth was a radially streaked cicatrix left. A very fine nevus data on the cornea showed the former site of the tumour.

Considering the effect of radium on eye diseases generally we had to come to the conclusion that the cases that had been raised had to suffer disappointment. In conjunctival affections (trachoma) its effects, as regards recurrences, had been doubtful. The great field for radium treatment in diseases of the eye lay in the treatment of tumours. Great caution has to be exercised in the treatment of deep lying tumours, but the irradiation of growths in the anterior chamber led to favourable expectations as to results.

Hr. Paul Lazarus had had a case of rapid recurrence after enucleation of a spongy mass below the eye. In that case he had introduced below the bulb and into the orbital fissure 250 mg of mesothorium radium bromide (200 of a 1 per cent, mesothorium solution and 50 mg, of 100 per cent, radium bromide), in small tubes and allowed them to remain for 30 hours. There was no reaction. In that 30 hours the tumour necrosed and melted away. The eye itself now showed no trace of burning neither internally nor on the cornea. Unfortunately the case was then lost sight of.

He could show resistance to the rays on the part of the nerve substance and brain in another series of cases. There was, in opposition to the notion that the action of the rays was limited to the lecithin content of the organ, that it depended on the splitting up of lecithin into cholin and that the action of the rays was to a certain extent identical with that of cholin. But the tissues rich in lecithin seemed to be the most resistant. The arrangement of the spermazoon was the most sensitive part of the tissue.

One of the dangers of radiation of the eye was the sensitiveness of the conjunctiva, that could be got rid of however by proper covering up. A second danger lay in the resorption of the tumour mass into the surrounding parts and in the hurling of any metastases that might be present into other tissues. It had been seen that when a tumour disappeared a fresh growth came in the buccal mucous membrane, or on the gums, or the lower jaw and grew rapidly. From the first it was not the tumour alone that was to be treated, but the whole of the neighbouring parts.

AUSTRIA.

Vienna, July 25th, 1914.

TENTH CONGRESS OF THE DEUTSCHER RÖNTGEN-GESELLSCHAFT.—(Concluded.)

IV.—PHYSICO-TECHNICAL ADAPTATIONS.

Dr. F. M. Fraedel (Frankfort a. M.) made a communication on "The Improvement of the Armamentarium and Auxiliary Apparatus for Röntgenography." He pointed out the following desiderata: (1) A new apparatus with a gasous apparatus; (2) A new apparatus; (3) The kino film has been improved, so that 15 pictures per second can now be taken. He believes, however, that the apparatus will never be such as to allow of experimental form of static with special provision for perfect focusing; the interpolation of a Nürnberg apparatus for tele-röntgenography, and a special apparatus for orientation of the camera in taking stereoscopic pictures, (5) The exposure to the exposure of the skin and for the display of the curve of the motions of the heart.

Dr. Holzknecht (Vienna) showed new models of Röntgen-ray apparatus (cameras, distinctor, radiometers, etc.). One was an exposure key, by which the periods of exposure were exactly tabulated.
shutter furnished a combination of distinctor and Bucky effect.

Dr. J. Rosenthal (Munich) discussed some of the questions of Röntgen-ray therapy of deep-seated organs, and pointed out the imperfection of present methods of measurements.

Dr. Eckert (Berlin) also discussed the therapy of deeply-placed organs, and demonstrated the use of suspended tubes with the help of an apparatus enabling the operator to move the tubes slowly over the patient's body. This arrangement gave specially favourable conditions for deep-seated therapy.

Dr. Braun (Solingen) discussed "Experiments with a Shutter for the Röntgen-ray illumination and photographing (Bucky effect)." He had used the Bucky filter in taking photographs and in illumination with the Röntgen-rays, and estimated its value highly. He found that the thicker the object the better it worked; it was then itself less prominently conspicuous.

Dr. Frick (Berlin) praised the Bucky filter, but pointed out that we must take account of the luminous quadrangles which are often found in a shadow-like shadow; also that distinctors are sometimes met with.

Dr. Bucky (Berlin) explained those phenomena. The bright spaces owe their origin to the metallic radiation, but can be minimised by using a screen of lead overlaid with copper.

Dr. Braun (Solingen) pointed out that the luminous areas were injurious only in taking photographs, not in the transmission of luminosity.

Dr. B. Walter (Hamburg) discussed the graduated values of gun materials for screens. He exhibited a combination of use in furnishing specific luminosities. The most valuable material in this connection is tin, so that a coat of tin of this metal may come into use. He also discussed the relative values of radium and mesothorium, and demonstrated with the help of a film in a mesothorium preparation represented two-thirds the cost of a radium one of the same strength.

Dr. Bucky (Berlin) then demonstrated the use of his "adaptateur," an instrument for measuring the progress of adaptation of the human eye to darkness. This consists of a lamp of which the intensity of light can be graduated, placed behind a green shade.

Dr. Grossmann (Charlottenburg) discussed critical data on the method of fields and the}

Dr. Tammelmann and Schütte (Berlin) discussed "Practical Experiments with the Fürsteneckschichtenmeter." This instrument has been constructed by utilising the action of the Röntgen-rays on selenium, and is an instrument of dosage—both for radium and for diagnosis. The instrument works satisfactorily, and can be rapidly adjusted.

Other dosimeters were exhibited by Dr. Levy-Dorn (Berlin) and by Dr. Hammer (Freiburg-Breisgau).

V.—Diagnosis in Affliction: (Sect. V. Various Regions and Growths.)

Dr. Franz Wohlauser (Charlottenburg) exhibited a large number of diapositives showing the changes demonstrable in tabetic ostepathy and the help of the Röntgen-rays. It was repeatedly happened in his personal experience that he was able to make a diagnosis of tubercles in its initial stages from the revelations made by the action of the rays. In one case he enabled the alveolar condition of combined tubercles and tubules; insomuch as a patient displayed a tabetic arthropathy of the knee-join, while the tibia displayed the typical picture of syphilitic bone disease.

Dr. Grashev exhibited radiograms in which failure of diagnosis had taken place, in which it might have been comparatively easily avoided. In a case of sarcoma of the neck of the femur, and in another of sarcoma of the vertebral column, a diagnosis of chronic inflammatory processes had been made. In another case, a diagnosis of sarcoma of the femur had been made, which on operation appeared to the naked eye to be a sarcoma; through it was diagnosed chondromata by the microscopic diagnosis. For the first time, after operation on a recurrent growth, the pathologist formulated the diagnosis of chondroplastic sarcoma. A specimen which displayed a portion of the epithysaroma of the odonoton has been pronounced to be one of fracture.

Dr. Graessner demonstrated a number of varieties of spina bifida occulta of the lumbar region in the living subject. The condition is one of frequent occurrence, and attains a practical interest in the second year of life, when lesions of sensation, deformities of the feet, and ulcers of the skin of the latter come to develop. In most of those cases the true diagnosis can be made only with the help of the Röntgen-rays. Early recognition is of the greatest importance, as improvement can be hoped for only after section of the cisternal bands and detachment of the adhesions within the spinal canal which have been pressing on nerve trunks. Spina bifida occulta could be found in 70 per cent. of cases of emressis in children, and of vaginal and uterine prolapse in women.

Dr. Nemenow (St. Petersburg) demonstrated a series of diapositives. Amongst them were cases of needles in the abdominal cavity—in a case in which 131 needles were removed from the stomach by operation, knitting needles in the bladder, pellets of kidney with double ureter, various abnormalities of gallbladder, and malformations in position of the chondrophy of elbow-joint, ulos ventriculi et dutoni, pneumoniae craniae.

Dr. Rosenblatt (Odessa) demonstrated a series of rare Röntgen-ray pictures. (1) A sarcoma of the ulna, in which the associated bone was resected and replaced by a piece of sibula. After eight months a recurrent sarcoma appeared in the transplanted head of sibula. The question arose of local extension of the traces left in the seat of the original disease or of metastatic adhesion of the sarcoma to the sibula before transplantation. (2) Congenital diverticulum of oesophagus. (3) Acquired oesophageal diverticula. (4) Blind ending of descending colon and canicular junction of flexura coli sinistra with abscess. (5) Carcinoma of duodenum.

Dr. Sabat (Lemberg) also showed rare specimens of Röntgen-ray pictures: craniosenosis, chondrostoma, hydro-pyopneumo-pericardium, arterio-sclerosis of aortic arch, hemiomenia of thorax, colitis ulcerosa tuberculosa, colitis tuberculous lesions, subphrenic abscess with formation of gas, large abdominal vesse.r which appeared like enormously dilated gall-binders.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Public Health Congress.

The concluding meeting of this Congress in Edinburgh was held on Monday, the 20th. The joint session of the State Medicine and Industrial Hygiene Sections was presided over by Dr. Leslie Mackenzie, chairman of the Edinburgh Medical School. The subject affecting the welfare of children. Dr. Brown, Medical Officer to the Govan School Board, discussing the nutrition of the school child, emphasised the importance of ante-natal conditions in relation to the health of the mother as influencing the nutrition of the offspring. He also showed that when a family income fell below 20s. per week, a sufficient diet could not be obtained. Dr. Trotter, M.O.H., for Paisley, read a paper on "Gripping in Action, Methods of Dealing with Infection and Infantile Mortality." His argument was that more discriminating treatment was required in connection with infectious diseases, and that it was not enough to introduce them into the more easily notifiable and the non-notifiable. The control of tuberculosis in Lanarkshire was discussed by Dr. Wilson, M.O.H. for the county. The Insurance Act had enabled the authorities to tackle the problem in a way undreamt of three years ago, and now they
had sanatoria and work colonies, hospitals, dispensaries, and special provision for the treatment of surgical tuberculosis, including an X-ray equipment. Many cases of the disease referred, up to the present about 90 per cent of the phthisis cases notified were beyond hope of permanent improvement.

After a paper by Dr. Margregor, Glasgow, on the cicatricial and ulcerous forms of tuberculosis in nature, Dr. Nathan Raw, of Liverpool, discussed the infection of children by tuberculosis, in which he reiterated the view that he has already expressed elsewhere as to the relation between human and bovine sources. He urged the sanitary aspect of the question, and the importance of preventing the infection of children by a tuberculous mother, which was most likely to arise in poor-class homes. A tribute was paid to the isolation of families of cases of tuberculosis with whom the writer worked in infection; he was convinced that the removal of older tuberculosis from homes was simply a question of time.

Dr. McWalter, Dublin, questioned the efficacy of notification, on the ground that it was a fallacy to look upon the tubercle bacillus as the efficient cause of tuberculosis. He regarded it mainly as a question of housing. After the discussion on the papers on tuberculosis a number of interesting communications were read, among them being Dr. Love's paper on "The Vaccine Treatment of the Complications of Scarlet Fever," Dr. Dittmar's on "Communal Cleanliness," and Dr. Paul Ritchie's on "Arthritis, Deformations and Industries to Industrial Conditions," which would seem that coal miners are more affected by the disease than any other class.

The Sections of Epidemiology and Child Welfare met together under the chairmanship of Professor Hunter Stewart. The principal discussion centred round Dr. Ker's paper on Isolation and Quarantine Periods for Infectious Diseases. The substance of the paper was read at a medical meeting some time since, and had already appeared in The Medical Press and Circular. On one of the chief questions—the infectivity of desquamation in scarlet fever—Dr. Ker was somewhat sceptical, and favoured a shortening of the period. Drs. Mead and Ethel Mead read a paper on infections as soon as the rash had faded, and quite possibly even when the catarrhal stage is over. For the sake of the patients themselves prolonged stay in hospital in cases of whooping cough was very beneficial; but it was very doubtful whether the actual infection lasted after the development of the whoop. In the subsequent discussion there was general agreement. The paper was read and discussed by Dr. Ker. Owing to the small attendance at the meeting of the Pathological Section the papers were not taken as read.

The Congress was formally closed by a meeting in the Asher Hall in the evening, when Dr. Otto Nachod delivered his address on "History of Public Hygiene." It was announced that next year the Congress of the Royal Institute of Public Health would be held in Brussels.

Insurance Act in Scotland.

The further points of interest in the annual report by the Scottish Commissioners, additional to those referred to a fortnight ago, concern, among other matters, the drug fund. The chemists thought that on the tariff of charges upon which they were allowed to base their accounts there would be some of the drug fund per person left over in every area. The Commissioners did not agree with this, and suggested that any proposal for increasing the tariff rates should be postponed until actual experience had been obtained. It has been found that the average cost for daily attendance in each case of adult and child in Stirlingshire, Argyll and Kilmarnock, to is. 10d. in Zetland and 2s. 11d. in Aberdeen. The floating fund has therefore had to be drawn upon in many areas. As regards sanatoria benefit this has been partly taken up by Insurance Committees, with the co-operation of Medical Officers of Health and the Local Government Board. Authorities have been able to co-operate with one another in providing sanatoria, etc., as was necessary in the interest of the patients. The paper of the Proprietary Sanatoria Committee is not to provide institutions, but to utilise institutions provided by other authorities. Scotland's share of the amount available for sanatoria under the Finance Act of 1911 amounted to nearly £60,000 which has been distributed equally among the 44 L.G.B.s approved comprehensive schemes by 5½ counties and twelve burghs, and the proposals of twelve counties and six burghs are still under consideration. The seventeen approved schemes cover 15½ million people, and of the eighteen proposals that have been made for 12½ million and a half millions, so that the total schemes under the notice of the L.G.B. represent over 50 per cent. of the population. The number of available beds has increased from 853 in July, 1912, to 1.290. For the eighteenth half-years 4,682 applications for sanatorium benefit were received, and 3,800 persons got sanatorium benefit. The total cost was nearly £140,000. The Commissioners lay stress on the field open to committees in the way of providing health lectures.

Proposal to Erect a Chair of Tuberculosis in Edinburgh.

At the last meeting of the University Court, Edinburgh, a letter was read from Sir Robert Chrishiston, Chairman of the Victoria Hospital and Dispensary, in reference to the endowment of a Chair of Tuberculosis in Edinburgh. The proposal was favourably received by the Court.

Alleged Cancer Street in Ayr.

The annual report of the Imperial Cancer Research Fund refers to an address which Sir Thomas Oliver delivered this year. He said that his attention had been directed to the report strewn with suspicion as to the existence between the years 1893 and 1908 nineteen persons and one dog had died of cancer. In some of the houses two or three cases had occurred. Since in nearly all these cases there was no hereditary history of the disease, the large number of deaths among successive occupants suggested, he said, that the matter was more than a co-incidence. Commenting on "cancer houses," Sir Thomas Oliver wrote:—It is not an agreeable subject for any medical man to see cancer germs lurk in houses." The street above alluded to is in the town of Ayr. Sir Thomas's native place. In consequence of his statements, an investigation was made on the spot under the auspices of the Imperial Cancer Research Fund, every facility being given by the local public health authorities. The street referred to is broad and contains the best type of residential detached and semi-detached villas, with gardens front and back. The householders, the reply states, being mostly retired business men or belonging to one of the professions, the average age is, therefore, higher than in other parts of the town. The age of the cases of cancer was in all the cases was below the age of 50, or 60, although only one could be verified. There was no positive evidence of infection of any kind whatever. So far as the investigations into the "cancer houses" and the "cancer areas already proceeded," concludes the report, "they accord with what has already been established by experiments on animals. 'Cancer houses' are as much a myth as are 'cancer cages.'

Medical Conditions in Mull.

The Highland and Islands Medical Service Board has been visiting Tobermory. The Board was represented by Dr. Norman Walker, Dr. J. L. Robertson, Senior Inspector of schools, and Mr. L. McQuibben, Secretary. Among other present was Dr. MacDonald from Iona. The chairman, Dr. Brown, said: "The object is to insist upon annihilating the difficulties of distance as regarded the out-of-the-way districts. During a discussion on the parish of Torosay, it was mentioned that the arrangements have been made as a result of the visit of a doctor in Salen. In reference to Dervaig, in Kilminnach parish, the United Free Church minister asked if any provision was to be made, now that Dr. MacLean had retired. Should the doctor happen to be at Lochaline, a good boat would have to travel between So and 90 miles to bring the doctor to that island. The general consensus of opinion at the Conference was that one large hospital should be arranged for at Tobermory to serve for Mull, Ardnamurchan, Coll, and Tiree.
LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

FORCIBLE FEEDING.

To the Editor of The Medical Press and Circular.

Sir,—I am afraid that Mr. McKenna's fear of the truth being made public has somewhat misled you on the subject of the medical deputation to that Ministry. His excuse for not receiving us immediately, as we immediately showed to be groundless, was the persistence of the case, and I think that your remarks might have accorded to the deputation a little more just appreciation than that "the matter fell through." To my mind it was improper on the part of Mr. McKenna to draw a line of demarcation between medical practice and the public, and thereby shirk a responsibility which he might have discharged. But in the majority of cases yield to the "stress" they are subjected to. If you consult Hansard you will recognise that these words signify nothing less than that the prisoners are tortured. It is true that the medical officers in the prisons are usually medical men, and therefore legally can be employed as torturers or executioners; but in our opinion the imposition of these reprehensible instructions and their obedience to them is contrary to all the ethical principles of the medical profession. All the points I wish to subordinate say—namely, and, as I have said before, it is quite obvious why Mr. McKenna declined to defend his administration in public. As regards the ridiculous question that he put in a letter to us,—namely, What is the alternative? there is only one possible method, as you say,—namely, full female enfranchisement. The existence of militancy has nothing whatever to do with the granting of such enfranchisement.

I am, Sir, yours truly,

Victor Horsley.

July 22nd, 1914.

To the Editor of The Medical Press and Circular.

Sir,—There can be no doubt, I think, that the ideas of a handful of medical men who are opposed to so-called "forcible feeding" are altogether untenable and ultra vires. What is called militant suffragism is nothing more nor less than another name for sex warfare, and the aim of these militant women is obviously to inflict the maximum amount of public injury with the minimum amount of inconvenience to themselves, and the latter is admirably achieved so long as they are allowed to commit crime ad libitum and escape prison through "an attempt to commit suicide" by starvation (a crime for so), in many cases repeating the same or other crimes whilst on licence. It is certainly unwarrentable that the lives and property of millions should be at the mercy of a few desperadoes, some of whom are demented, and whose ranks can be readily repleted as they fall out one by one under the present easy-going conditions, and who hope by a system analogous to guerilla warfare to exhaust public patience and ultimately achieve their end through violence and public abuse.

It is the duty, therefore, of the Government, so far from discontinuing forcible feeding, to resort to it as a preliminary in every case of "attempted suicide" or hunger strike, otherwise they manifestly admit to prison for one offence and release them under "temporary discharge" for another.

I am, Sir, yours truly,

Clement H. Siers, M.R.C.S.

5, Chantreyton Head, Hove.

July 23rd, 1914.

THE DECAY OF FRANCE.

To the Editor of The Medical Press and Circular.

Sir,—The letters on the decay of France which have appeared in recent issues of your publication have been full of interest to every thoughtful individual. As the writer of them remarks, "the population question is the fundamental question of the day. You cannot, however, take a limited view of the matter; as I read him, he is imbued with the idea of imperial domain both for France and England. He considers it necessary to make the mother country the nursery for prospective enfringants of whom will carry with him the flag of his country to maintain its supremacy. Is the imperial idea a correct one? More important than the welfare of France or of England is the well-being of the world as a whole. Now, the population of the world is a more or less constant ratio to the amount of available food in the world. It is not a question of money; it is the fundamental question of meat and drink. There would be no surplus population if there were enough food for everyone. How far this is due to economic short-sightedness and imperial wastefulsness is a question still to be discussed, but the chief factor at present in its causation is the over-population of the world. The available amount of food in the world is sufficient for a number of people. Express this number as x. The total population is then expressed as x plus the surplus for whom there is not a sufficiency. When millions in India were starving to death there was more food than could be cultivated, but there was not enough food to be bought. It might be argued that our surplus population could be employed to make the desert arable and the jungles fruitful, but that would mean a total abandonment of the war-staten. It is in the interest of the world to act as drags on the wagons of the pioneer and rob him of his just reward. Besides, as your correspondent points out, the surplus population is not fit for such work, it has to be culled in workhouses, gaols and asylums. To the universal it matters not whether France decay or England wither. Patriotism is un-Christian, for it implies the waxing of one power at the expense of another's waning. As long as there is not enough land under cultivation to supply the needs of men, every nation and nations to decrease the population is expedient and excusable. Better, however, than this would be the acquisition of sense by the collective intelligence in order that money should be spent on what will provide potential bread, and not on that which profligates it.

I am, Sir, yours truly,

Neo-Malthusian.

REVIEWS OF BOOKS.

PRACTICAL HORMONE THERAPY. (a)

There can be no question that the therapeutic use of organic extracts and internal secretions is a very fascinating subject, and the brilliant results achieved with one or two substances are such as to justify the author insisting on the "positively enormous" prospects held out by this line of research. Still, we must not blink the fact that at present our knowledge of the subject does not go very far, and that further progress is conditional on difficult, painstaking observation. Writers on the subject will therefore do well to take the diplomatic maxim to heart, "Surtout point de zèle." We shall not advance our knowledge by arguments based on statements that this or that organ "controls possibly in some way another organ." We should be safer and sounder if such has been shown to be the case. Nor can we set much store on results of organotherapy in such vague disorders as ovarian dysmenorrhoea, neurasthenia, or hyperæmia.

It is readily conceded that the author has given us an exhaustive and voluminous treatise on organotherapy: he tells us all that is known—and a good deal that cannot by any stretch of imagination be said to be known. His work will certainly stimulate inquiry and

(a) "Practical Hormone Therapy." By Henry E. ATVATER, M.D., late Professor of Clinical Diagnosis, Loyola University, Chicago. London: Balliere, Tindall, and Cox. 1914. Price £4 net.
will prompt many a reader to ascertain for himself what measure of usefulness attends the employment of the less well known of these organic extracts. We cordially agree with the author's remark that "some of the statements regarding the therapeutic applications of endocrinian preparations are strange, to say the least," for whoever would imagine the use of placental extract as a remedy for alopecia or of adrenal extract as a cure for sea-sickness.

The principle of the use of these therapeutics — viz., to supply to the body a particular hormone or combination of hormones which, through disease, has been diminished or lost, is certainly a most reasonable one, but unfortunately these hormones are, for the most part, difficult to obtain, the evidence whereof is inferred rather than demonstrated. In any case, it is to be hoped that preparations of these hypothetical substances will not be named according to their fancied action. We already have "leukodrines," "vasoconstrictors," and a few others which must horrify both the physiologist and the philologist.

What, then, are the substances the use of which in therapeutics may be said to have a scientific basis? Well, of course, first and foremost comes thyroid extract, then adrenalin following by pituitrin, possibly thymin, ovarian extract, luteal extract or lutein, and—well, this is about all, because the action of the last three is by no means established, that last would seem to be a medicinal effect. Take the placental hormone, for instance; one man says it increases the flow of milk, the next man contradicts this, but finds that it causes uterine contraction, while a third brings it forward as a remedy for apoplexy.

The task of assigning a particular therapeutic function to the individual gland is often so great that organo-therapeutics fall back on pluriglandular extracts, a sort of polyvalent stew, eye of newt and toad of frog," the use of which, observes the author, "is by no means as unscientific as some might think . . . since some of the failures following the use of a single animal extract may be obviated by combining it with one or more synergistic extracts."

The reason for this phenomenon is to be found in a brilliant future for organotherapy, and works like this one which synoptise the results obtained by countless scientific labourers are of immense service. But do not let us get into a state of hysterical excitement over mere possibilities, let us abstain from such language as that in which a distinguished English physician recently referred to the subject. "The internal secretory glands already unfold before the astonished view of the seeing eye a land of promise beside which the vast area of the brain, covered by Lister and Pasteur, is destined to pale into honorable insignificance. The ductless glands and their hormones come to us as peaceful conquerors who brook no denial. They lighten our darkness and show us miracles. In studying them and endeavoring to unravel their intricate and esoteric mysteries one sees ever and anon to be on the trail of the Great Secret and in danger of losing one's mental perspective."

LITERARY NOTES.

Those of our readers who were fortunate enough to secure a set of Mr. Hanslin Fletcher's realistic sketches of Guy's Hospital, published a short while ago, will be glad to learn that the same talented artist has just executed a fine series of eight drawings of St. Bartholomew's Hospital. The plates, which measure 17 in. by 11 in., including margin, are replicas of the beautiful wash drawings made by Mr. Fletcher only a spring ago. The view of the Priory Church interior is a noble study in colour, the others are in monochrome. The subscription price for artist's signed proofs, printed on Japanese paper, with plate paper mounts, is two guineas the set. Bart.'s men in all parts of the world will welcome this opportunity of possessing these delicately finished and wholly representative drawings of their alma mater.

The plates are issued by Messrs. W. H. Beynon and Co., Fine Art Publishers, St. Alban's Lodge, Chelsea.

MEDICAL NEWS & PASS LISTS.

Medical Sickness and Accident Accident.

At the usual monthly meeting of the Executive Committee of the above Society, the half-yearly balance-sheets were submitted and it was stated that the Society's funds amounted to £26,000, and the income of the Society is well over £15,000 per annum, and shows a steady rise every year. The grateful letters from members who attain the age of 65 and over, and from the families of those who have reached an age satisfactory to those under whose careful management the Society has prospered sufficiently to enable this bonus to be paid, and the amount actually paid increases every year, and touched £3,500 in 1891. This fact proved that many attain 65 years, and that insured medical men are, taken as a whole, good lives.

The claim account presented was slightly lower than that of last year, and was under the expectation provided for by the tables.

Death under Ether.

Mr. W. Schiödner held an inquest on the 17th inst. at St. Pancras concerning the death of Anna Grabot, aged 43 years, who died at the New Hospital for Women and Children, 59, Euston Road, under an operation.

The evidence showed that the deceased, the wife of a cabinet maker, had been ailing for the last few years with pains in the back and internally. The previous day she went to the New Hospital, 59, Euston Road, as an out-patient, and there, after examination, was told that she was suffering from an internal growth, and that it was advisable she should become an in-patient and undergo an operation for the removal of the growth, to which she consented. On Tuesday afternoon she was prepared for the operation, which was for the removal of anæmia. The operation was completed it was noticed that a sudden change came over her. Restoratives were used, and the operation quickly completed. Deceased had a second relapse, and died a few minutes later. On a post-mortem examination being made by Miss Goldby, one of the House surgeons, it was found that there was a cancer of the heart and liver. It was found that the cancer was of old standing. Death was due to syncope owing to latty degeneration of the heart whilst under the influence of the anaesthetic.

Dr. Miss Nora Payne observed that the deceased was an administered ether, which she had taken very well indeed. The operation was a long one, occupying over two hours. Suddenly she noticed there was a change in her condition, on which every endeavour was made to restore her, but she never regained consciousness, death being due to fatty degeneration of the heart, accelerated by the anaesthetic. Witness had given anaesthetics in over 3,000 cases successfully.

The jury returned a verdict of "Death by misadventure."

Landlord's Responsibility for a Defective Drain.

At the West London County Court, on the 21st inst., Judge Selle delivered a considered judgment in a case in which a landlord was sued on the ground of an illness said to have been caused by a defective drain.

In December last Mr. Matthews, of Hurlingham, let on lease to a Mr. Worthy the house at 15 Comber Road, Parson's Green, at £36 per annum. Shortly after entering into occupation Miss Worthy complained of the water in the cellar being too strong to be entered into. An examination of the house drains disclosed a crack in the main sewer, from which sewage had saturated the surrounding soil, while gas was also given off. The plaintiff claimed £100 damages.

His Honour found on the evidence that defendant had let the house without having the sanitary arrangements examined. Since the medical evidence agreed
that enteric fever is caused by a bacillus entering the system, and that he was caused by merely inhaling sewage gas, his Honour did not feel justified in finding that the enteric fever was directly caused by the defects in the sewage arrangements. His Honour found, however, that a person whose general health was affected by these minor insanitary conditions, as Mrs. Worley's was in this case, was more liable to enteric fever than a person in normal health. If the enteric fever had not supervened Mrs. Worley would have required some medical treatment, and he did not think the defects should be considered breach of the Houses and Town Planning Act. He assessed the damages at £15 with costs. If, however, it was decided on appeal that the fever was the direct result of insanitary conditions, he assessed the damages at £95, with costs on the highest scale.

The Unallocated Funds.

A MEETING of the Insurance Committee for the County of London was held last week at Spring Gardens. Mr. Fred Cusby was elected Chairman of the Committee for the ensuing year, and Mr. J. Howarth was elected Vice-Chairman.

Replying to a question, Mr. Frank Briant, London County Council said that he had been received from a solicitor stating that he had been instructed by Dr. H. Basset to bring an action against the Committee to make it disgorge monies that had accumulated during the last year, through insured persons not selecting a doctor.

Mr. C. C. Greenwood stated that since May the number of deposit contributors in the county area had decreased by 4,449. If that rate continued, the committee would not be able to repay the moneys contributed within a short time. In regard to the distribution of monies in the panel fund for last year, the Medical Benefit Sub-Committee recommended that as the Insurance Committee was unable to agree as to the method of distribution, the Insurance Commissioners be requested to distribute such monies among the practitioners on the panel.

Mr. C. C. Greenwood thought the proposal was an easy and simple way of ending the controversy. He made an appeal to members to dispose of it, in order that they might all "pull together" for the benefit of the insured persons.

The sub-committee's recommendation was carried by 36 votes to 10.

Unstamped Medical Preparations.

At Marylebone last week, Mr. Biron heard a summons at the instance of the Customs and Excise against Samuel Simpson, of Brondesbury, trading as James Alfred Simms, at Paddington, for exposing for sale or selling as medicine, remedies, without Revenue stamps attached and without having a licence.

The defence was that the question was whether the defendant or someone else was liable for the duty. The prosecution must show that the defendant was the proprietor, or original vendor of the articles before they could make him liable for the duty. The defendant bought wholesale and had no prescriptive right in the medicines at all.

Mr. Biron ordered the defendant to pay fines amounting to £21 1s. 6d., with costs.

Mr. Paul Taylor heard a similar case in which Isaac Rowe, trading as I. Reid and Co., of Edgware Road, was summoned. The defence was the same as in the previous case. There were six summonses, and Mr. Paul Taylor fined the defendant £1 on each summons, £6 in all, with £2 2s. costs.

University of London.

The following have passed the M.D. examination for internal and external students:

Branch II: Mental Diseases and Psychology.—C. S. Ricklund, B.S. Coll. Gen.

Branch V: State Medicine.—H. L. Hopkins, Guy's Hosp.

Branch VI: Tropical Medicine.—M. F. Reaney, London Hosp. and London School of Tropical Medicine.

The following have passed the M.S. examination for internal and external students:

London School of Tropical Medicine.

The following candidates have passed the examinations during the session May—July, 1914:

The following passed with distinction.—A. C. Munro (Capt. I.M.S.), M.B.Glasg. (awarded the Duncan and Lallaca medals); C. Bonne, M.B.Amsterdam; J. M. Stenhouse, M.B., B.C.Cantab., J. S. Webster, M.B.; Ch.B.Victoria.

Royal College of Surgeons of Edinburgh—Fellowships.

Royal College of Surgeons in Ireland.

The following candidates have passed the mentioned examinations, July, 1914:

Primary Fellowship Examination.—Moses Briscoe, Robert A. Keane, John A. C. Kidd, Robert C. B. Ramsay.

Final Fellowship Examination.—Andrew R. D. Carbery, Frank M. Fonsceca, Lady A. Menezes, John O'Leary, Balwant Rai, Jerome Suareas, Hassan Suvarhataya.

Final Dental Examination.—Walter G. Keys, Arthur C. Wiley.
Abdominal Cesarean Section in Eclampsia.—Peterson (Amer. Jl. Obst., lxix., 4), from facts gathered during the past three years, comes to the conclusions that the operative results during the five years from 1918 to 1923 have so improved as to make operation in cases of Cesarean section amongst other obstetric operations in the treatment of antepartum eclampsia. The statistics show that the earlier the operation is done after onset of convulsion, the better the result. The mortality, maternal and fetal, is not so high as to the right of Cesarean section amongst other obstetric operations in the treatment of antepartum eclampsia. The statistics show that the earlier the operation is done after onset of convulsion, the better the result. The mortality, maternal and fetal, is not claimed that every woman developing eclampsia should be operated upon, but that the operation should not be condemned without a hearing, because the results obtained are improving rapidly; it must be considered seriously, although other methods from a statistical standpoint are superior. The operation is contra-indicated when attempts at delivery have been made from below or many vaginal examinations made. The operation will very rarely be indicated before the eighth month and is not advised for the unskilled practitioner. When the operation is decided upon, it should be done as early as possible.

The Serum Diagnosis of Pregnancy.—Jellingshaus (Amer. Jl. Obst., lxix., 4), in a long paper concluding with a detailed account of the technique of the test, concludes that Abderhalden’s defensive ferment theory is correct, but that the dialysation method has not always been correct in the pregnant cases, but so in the non-pregnant ones. Since uniform results have not been obtained the test cannot be recommended as diagnostic purposes. Many of the writers who have used the test for this purpose, when they obtain a positive result in a case which proves to be not pregnant, blame it upon some error in technique or impure placental albumen. Since the error is not detected until the case is made evident, the method must be looked upon as useless until the technique is improved so that errors can be positively avoided. Much of the literature condemning the dialysation method is due to the fact that the writers have not reported a few non-pregnant cases. The claim that eclamptic serum contains less ferment than normal pregnant serum is not substantiated, and was not found by the author. The method is entirely a laboratory procedure and absolutely unsuitable as an office test.

Influence of Ectopic Pregnancy on the Uterus.—Sampson (Amer. Gyn. and Obst., xviii., 5). In twenty-five cases the uterus was removed on account of ectopic pregnancy, or because of the tendency to recurrence of the condition in the other tube or because the other tube required to be removed. The specimens were immediately injected and examined by X-rays and microscopic section, and it was found that under the influence of early ectopic pregnancy the uterus thickened more than normal, due to hyperemia and increased size of muscle fibres is not certain. The changes in the endometrium are quite similar to those found in early pregnancy. The entire lining of the uterus takes part in this change. The trabeculae and the compact layer of the endometrium are more evident than in the non-pregnant uterus, but not so evidently in early uterine pregnancies. There is often a decidual reaction around the blood-vessels in these trabeculae, and the development of the compact layer and also the decidual cells seems to be intimately associated with the arterial invasion of the endometrium, which takes place throughout the trabeculae. Venous spaces are also very evident. It is difficult to detect any change in the uterine wall other than arterial and venous hyperemia.

the complete termination of the tubal pregnancy uterine involution takes place. The uterus becomes smaller, due to decrease of arterial and venous hyperemia and increase of the endometrium. There is possibly a certain amount of sclerosis of the radial arteries and their branches. The earliest regressions changes detected were dilatation of the veins spaces and escape of blood into the tissues of the endometrium. The regressive changes are apparently due to uterine contractions injuring the structures of the endometrium, interference with the arterial circulation, a condition of venous congestion. Rupture of the superficial venous spaces would give rise to uterine bleeding and involution of the endometrium, while rupture of the venous spaces at the junction of the compact and spongy layers separates the two layers and may give rise to a decidal cast. In the majority of cases the termination of the pregnancy is a gradual process associated with repeated attacks of pain, and some of the products of conception may remain active in the tube for some days or weeks after the commencement of the termination, and therefore the process of involution is delayed in the uterus.

Spinal Anesthesia in Pelvic Surgery.—Ansprech (Amer. Jl. Obst., lxix., 4) reports thirty-six cases treated, and draws the following conclusions, that even in skilled hands there will be a higher immediate mortality as a routine anesthetic than either ether, chloroform, or nitrous oxide. It has no post-operative mortality of morbidity, and in this respect it is superior to the other general anesthetics and nitrous oxide and oxygen. It is more troublesome to the surgeon, and should not be used unless the surgeon has familiarised himself with all the details of the technique; he should also be fully aware of the complications likely to arise. Spinal anesthesia is the best form of anesthetic in selected cases, but should be reserved for those operations in which the dangers of general anesthesia are increased.

Predetermination of Sex.—Brum (New York Med. Jl., June 6th, 1914) records the result of his efforts towards the predetermination of the sex of the infant in the case of thirty women who were under his care. He based his procedure on his observations that excess of nourishment of the mother predisposes to the birth of a female child, while deficiency in nourishment predisposes towards the birth of a male. Further, that the sex of the infant is largely determined by the activity of the adrenal glands of the mother, and where deficiency in this activity exists a female child is likely to be formed. Of the thirty patients twenty came under treatment during the first two months of pregnancy, and ten after the second month. These mothers all desired to have male children. These patients were all put on a strict diet till after the fourth or fifth month of pregnancy. Rich albuminous food, such as eggs, meat, fish and cheese, were strictly forbidden, and the diet largely consisted of such substances as cereals, fruits, potatoes, milk, buttermilk, and butter. Each patient was given after each meal a capsule containing two grains of the extract of suprarenal gland combined with four grains of lecithin. Of the twelve patients who came under treatment before the end of the second month of pregnancy all gave birth to male children, and of the remaining ten six gave birth to male children. Brum concludes that it is safe to say that we probably have definite means for the predetermination of the male sex if the following essentials of treatment are carried out. Treatment should be instituted immediately after the woman has missed her period. Foods rich in albuminous nitrogenous materials should be inter-
dicted. Extract of supra-renal gland combined with lecithin should be administered regularly and the treatment continued during the first five months of pregnancy.

K.

Emetine in Dysentery.—Friedenwald and Rosenthal (New York Med. Jl, July 4th, 1914) describe the result of the treatment of nine patients dysentery by means of emetine. The patients, seven males and two females, ranged in age from 10 to 42 years. The anaebas were demonstrated in all cases except one. The treatment was begun, but could not be observed after the first day of treatment. The patient in whom they were not found had been having frequent injections of argyrol. The result of treatment, however, was so marked that the treatment was repeated in the second attack diagnosis. The protocose was used in all instances and the ulcers observed, scrapings being taken for the demonstration of the organisms. Examination of the blood showed a high leucocyte count, which diminished as the disease abated. The drug was employed hypodermically in the form of the hydrochloride in doses of from one-third to one-half a grain three or four times daily for about a week. In all instances the drug was well borne. In a few instances purging occurred to the point of the whole body, but this symptom always disappeared within a week or two. Usually after the third or fourth injection the stools began to lessen in number, from eight to ten a day to one or two; the bowel movements disappeared entirely and the bowel could no longer be felt. In all instances the patients improved rapidly in general health, and the rectal ulcers disappeared after a week or ten days. As a result of their experience, the writers came to the following conclusions:—Emetine is a specific in the treatment of amoebic dysentery. It is quickly absorbed, and its effect is rapid and striking. It produces no unfavourable symptoms, such as nausea, vomiting and depression. The drug is not altered in the intestines, and is absorbed with but little modification. It is not influenced by this remedy, so that its employment as a diagnostic measure is of the greatest value. Recurrences after apparent cure are not infrequent, and therefore it is best to treat all cases showing a tendency to relapse intermittenly with emetine.

Appendicular Grafting.—Braham (Brit. Med. Jl, July 11th, 1914) reports that a boy, aged 11, fell when walking on a railing and bruised his perineum, causing extravasation of urine. The tissues in the groin were incised and a catheter passed through a supra-pubic cystotomy. Excessive straining ensued and loss of the distal portion of the urethra. Two months later (November 1913), an unsuccessful attempt was made to reconstruct the urethra. Another attempt in March failed. At the end of May, 1914, the writer dissected out of the proximal and distal portion of the urethra in the perineum, and removed as much scar tissue as possible. At a resected portion of the spheno-sonas vein was found to have too small a calibre, the patient's appendix was removed and used as a graft. The serous coat of the appendix was scarified and half an inch of its distal end removed, the whole graft being over an inch in length. A rubber catheter was passed through the penile portion of the urethra and the appendix then threaded on it. The point of the catheter was then passed into the bladder. It was then quite easy to unite the mucous membrane of the urethra and the appendix at either end, and that being accomplished, the wound was supported. The catheter came out in four days, but was replaced under an anaesthetic of it's distal end removed. Nine days after the operation the catheter was left out, the perineal wound was healed, and the urine has ever since passed naturally. The boy is about, and mitractates freely and normally without discomfort.

NEW PREPARATIONS.

BURROUGHS WELLCOME'S TABLOID "XAXA" COMPOUND.

Under the formula—

Rx.

"Xaxa" 34 gr.

Propylenin 2 gr.

Caffeine 4 gr.

is presented a convenient means of administering pure acetyl-salicylic acid combined with phenacetin and caffeine. In this product Burroughs Wellcome and Co. have introduced a combination of anti-atheritic, antipyretic and analgesic agents, which may be employed to advantage without any risk of producing gastric disturbance. The tabloid disintegrates easily and is rapidly absorbed. The analgesic and anti-pyretic properties of the contained phenacetin should assist in relieving pain, reducing temperature and combating pyrexial conditions generally, while the addition of caffeine tends to obviate the depression which occasionally follows the use of phenacetin.

"TABLOID" TRIANGULAR BANDAGE.

The use of the triangular bandage in first-aid work is well recognised, and it has been customary to print upon the bandage the directions for the method of application. An advance in the quality and clearness of the pictorial representations has recently been effected in connection with the "Tabloid" triangular bandage. The designs are plain, precise, complete, and in accordance with the latest practice. Another point of importance is that these particular bandages are compressed into a small space, one bandage occupying no more room than a match-box, and they can, therefore, be carried without inconvenience in the pocket of the first-aid man. Each packet is provided with a stout covering which will resist wear and tear.

The ideal bandage, of course, one that is free from all septic matter, and in order to provide such a dressing, Messrs. Burroughs Wellcome and Co. issue a bandage compressed and sterilised, in germ-proof envelopes, which are readily removed and yet not hot. The retail price is 6d. per packet of two, the sterilised variety one penny extra.

Clinical Congress of Surgeons.

We are asked to announce that the medical staff of the Central London Throat and Ear Hospital, Gray's Inn Road, invited their American correspondents to breakfast at the Great Northern Railway Hotel, at 9 a.m. on Thursday, July 30th, and at 10 a.m. to visit the hospital.

Cards of invitation on application to the Dean.

NOTICES TO CORRESPONDENTS.

Correspondents requiring a reply in this column are particularly requested to make use of a Distinguished Signature and Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by the attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad.

ADVERTISEMENTS.

For advertisement:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 6s.; One-eighth, 12s. 6d.

The following reductions are made for a series—Whole Page, rapidly inserted £3 10s.; 3½ ins. at £3 3½; 3 ins. at £3; and pro rates for smaller spaces.

Small announcements of Practices, Assistants, Vacancies, Books, etc., 10 words (70 words), 4s. 6d. per insertion: 6d. per line beyond.

Dr. William Bruce, M.D., of 34, Greenhill Gardens, Edinburgh, late surgeon to the Duke of Buccleuch's Militia at Dalkeith, left estate of the gross value of £16,263.
MEDICAL PRACTICE IN THE FEDERAL DISTRICT OF RIO DE JANEIRO.

To the Editor of The Medical Press and Circular,

Sir,—By the courtesy of the Privy Council I have received a copy of a despatch from His Majesty's Consul-General at Rio de Janeiro stating the conditions under which persons holding foreign diplomas are permitted to practice medicine, surgery, and dentistry within the federal district. I send a copy in order to show to those who care to call at this office; it will be incorporated in the next edition of the pamphlet, published by the Council, giving the conditions under which憋 persons qualified in their own country may practice abroad.

Yours faithfully,

NORMAN C. KING,
General Council of Medical Education and Registration,
299 Oxford Street, London, W.

STAFFORD (Edinburgh).—In reply to your enquiries (a) we have it on the authority of the Register-General that no fatal case of small-pox occurred last week throughout the United Kingdom; (b) the publication of Abrupt is not officially given in the returns of Great Cities and Towns, but is, we understand, about 60,000. That of Edinburgh, according to the latest census returns, is given as 320,000, and that of Glasgow 1,467,000.

PRIZER.—The matter is one requiring consideration, and, after due inquiry, we will communicate with our correspondent privately.

Yours,—We shall be glad to consider the proposed article.

THE MEDICAL DIRECTORY.

To the Editor of The Medical Press and Circular.

Sir,—The annual circular of The Medical Directory has been posted to every member of the medical profession. Another copy will be forwarded on request, should the first notice have inadvertently gone astray.

It should be the practice of practitioners will kindly co-operate in returning forms to us promptly, so that the entries may be as accurate as possible.

To meet the convenience of purchasers, the Directory will be on sale this year EARLY in the month of December.

We are, your obedient servants,
J. H. and A. CHURCHILL.
7 Great Marlborough Street, W., July 25th.

T. D. (London, W.)—We regret that through the negligence of clerks in the Low of London we are unable to publish your letter.

Vacancies.

Certificate Factories Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Ashton-under-Lyne (Lancashire) (Ralph Beswick), Hulme Dispensary, Dale Street, Stretford Road, Manchester.—House Surgeon. Salary £100 per annum, with apartments, and 15 per cent. on all amounts. Application to Mr. W. G. H. Bennett, Secretary. (See Adv.)

Bolton Infirmary,—Sanitary Dispensary.—Senior House Surgeon. Salary £120 per annum, with board, residence, and laundry. Applications to T. Elwyn Kershaw, Secretary.

Bootle Borough Dispensary.—House Surgeon required. Salary £120 per annum, with residence, board, and laundry. Applications to the Secretary, 71 Oriel Road, Bootle, Lancs.

Bristol City Hospital.—Assistant Medical Officer. Salary £200 per annum, with furnished apartments, board, washing, and lodging. Application to the Medical Superintendent, Maidstone. (See Adv.)

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, board, attendance, coal, gas, garden produce, milk, and washing. Applications to Medical Superintendent, Maidstone, Maidstone.

Hull Royal Infirmary.—Senior House Surgeon. Salary £150 per annum, with board and furnished apartments. Applications to Chairman of Committee.

North Lansdowne Hospital, Barns-in-Furness.—House Surgeon. Salary £100 per annum, with residence, board, and laundry. Applications to the Secretary.

Northampton General Hospital.—House Surgeon. Salary £220 per annum, with apartments, board, washing, and attendance.

Appointments.

DEILD, GERALD C., M.B., Ch.B., Manchester, Second House Surgeon to the Manchester Royal Eye Hospital.

FLEMING, G., M.D., C.M., North Bristol Bootle.

HULME.—Senior Medical Superintendent to the Durham County Sanatorium.

KOOGAN, CHARLES L., M.R.C.S., L.R.C.P., Honorary Assistant Physician to the Municipal Hospital, London.

MILLER, S., M.B., B.Ch., House Surgeon at the Royal Victoria Hospital, Manchester.

MURPHY, W. MAXWELL, M.B., Ch.R.Edin., F.R.C.S., Surgeon to the Ear, Nose, and Throat Department at the Dewsbury General Hospital.

SUTHERLAND, GEORGE W., Ch.B., Ch. Surgeon, Resident Surgical Officer to the Manchester Royal Eye Hospital.

Births.

HOLLAND.—On July 22nd, at 35 Essex Anne Street, the wife of Earle Holland, M.D., of a daughter.

PASMORE.—On July 21st, at Chesham House, Warrington, the wife of Dr. E. S. Pasmore, M.R.C.P., of a daughter.

REWS.—On July 19th, at Watton Grange, Bedfont, Middlesex, to Dr. and Mrs. Rev. daughter.

Marriages.

BAROES-ABEL SMITH.—On July 25th, at Southwark Cathedral, Barley Barou, son of Dr. and Mrs. Barley Barou, of Clifton, Bristol, to Rachel, daughter of the late Abel Smith, M.P., and of Mrs. Abel Smith of Crowbury, Hertford.

D'OLIVARIAN—HUMPHREYS.—On July 21st, at St. George's Cathedral, Southwark, Thaddeus Turner O'Callaghan, Surgeon, elder son of P. T. O'Callaghan, of West Norwood, to Adelaide Humphrey's, youngest daughter of the late Thomas Humphreys, of Ennute House, Chester.

TOOMEY-ABBOTT.—On July 22nd, at Holywood Church, Somerset, Dr. Frederick Tooth, of the Old House, Nethew, Stowey, Bridgewater, to Kathleen, daughter of Mrs. Archer, of Aller Park.

Deaths.

BARTON.—On July 29th, at Cheetham, Edwin William Barton, M.D., of Swallow, Lodge, Markham Bury.

BERRY.—On July 21st, at Romiley, Amelia Elizabeth, second daughter of the late John Betty, M.D., on July 21st, at Swinton, under 12 year's, 179 Jerningham Road, New Cross, London, James Montague Brand, surgeon, late of Stratton, N. Cornwall, in his 84th year.

KILGOUR.—On July 21st, at Chelsea, Frances, daughter of the late John Stewart Kilgour, M.D., of 2 Keynsham Bank, Chlesea.

RIVER,JONES.—On July 25th, at 4 Chesham Place, Gwендolyn, the eldest daughter of Dr. and Mrs. Ridg-Jones.

HULME DISPENSARY.

DALE STREET, STRETFO RD ROAD, MANCHESTER.

WANTED 3 HOUSE SURGEON duly registered and fully entitled to practice. Salary £300 to £420 per annum, with apartments, coal, and gas. Applications, with testimonials, at once, to Honorary Medical Secretary.
NOTES AND COMMENTS.

The verdict of those members of the Aberdeen British Medical Association who attended the annual meeting in the B.M.A. was that it was a most successful gathering. The native attractions of the "Silver City" are sufficient in themselves to ensure the pleasure of visitors at any time, but last week these wereenhanced by fine weather and the splendid welcome extended to the Association by the local medical men and the citizens who did all in their power to entertain the members. One feature of the scientific proceedings will be connected with the Aberdeen meeting, and that is the prominence given in the three great addresses to medical history. Perhaps something in the atmosphere of the place itself, with its ancient and historic university and other associations, may have been responsible for this retro- spective vein of thought. It must not be supposed, however, that these discourses were for this reason inferior, from a scientific standpoint, to those of previous years. On the contrary, all three were of a high order and full of suggestiveness.

In view of the increased interest now shown in medical history it might almost be as well to add a new section or a sub-section specially to consider matters within its province at future annual meetings of the Association. Next year, at Cambridge, the propriety of so doing seems to suggest itself, and we beg to submit the proposition for the consideration of the Council of the Association.

The place of the Queen Alexandra Day Fund in the heart of the nation stands unaltered by the success of the Queen Alexandra Rose Day collection in aid of the London hospitals. After all expenses have been paid, the secretary, Miss C. May Boonan, has had some £20,000 to distribute, or about £6,000 more than the amount available last year. It is gratifying to note that the chief item of expenditure was that incurred in the purchase of the roses sold by the ladies who kindly acted as volunteer street collectors. This year the distributing committee under the Lord Mayor have made their grants upon a new and far more equitable system than that adopted in former years. It is understood that Queen Alexandra indicated, at the desire of the committee, certain hospitals to be benefited to the extent of £6,645. The result is that many small hospitals have for the first time participated in the grants of this most popular Fund, a fact that will do not a little to advance its prospects in the future. Some large grants have been made this year to some of the great and wealthy hospitals. It is not altogether easy to understand why citizens should be asked to contribute in the streets to a charity which literally draws in funds by special appeal in hundreds of thousands of pounds. On the other hand, there is every reason why the man in the street should contribute to the support of the small and special hospitals which minister to his needs and have done so for many a year, and some of the best and oldest of which are ignored by the King Edward Fund, which is gradually crowding out of existence the Hospital Sunday Fund.

The recognition of the small and special hospitals by the Alexandra Fund Precedent marks a change of policy that is consonant with the universal kindness and tact which has always characterised our Royal Family in these matters. The small hospitals, in spite of their many years of usefulness and their great share in the advance of medical science, are ignored, except in a few special instances, by the King Edward Fund, whose awards are made by a small committee, which includes no representatives of the small and special medical charities, but is composed of medical men and philanthropists, who, however amiable and beyond reproach individually, have nevertheless been always identified with a policy of absolute non-recognition of the smaller medical charities. The Medical Press and Circular has consistently raised its voice against this defect in the administration of the Hospital Sunday and the King Edward Funds. It has again and again contended that the fundamental error is to be found in the non-representative nature of the two Funds in question. The Hospital Saturday Fund, in which the small institutions are adequately represented, bestows its grants upon great and small alike. A system that collects huge sums of money from all classes of society and then entrusts its distribution to a small board of persons who rigidly exclude the smaller institutions must always remain open to the more or less grave suspicion that public interests are subordinate, in some instances at least, to private prejudices. Hence the supreme importance of the wider and more liberal extension of grants to all sorts and conditions of hospitals inaugurated by Queen Alexandra.

At an inquest held last month at Myrtle Hill, Lichfield, upon the body of a groomsmen who died from the effects of a horse-kick in the abode, the medical man who gave evidence took the opportunity of calling attention to the pressing need for the establishment of cottage hospitals in rural districts. The exact nature of the injuries sustained by this unfortunate man was not stated, but it is within the bounds of possibility.
LEADING ARTICLES.

THE ADDRESS IN MEDICINE AT THE ABERDEEN MEETING OF THE B.M.A.

In the annual Address in Medicine delivered before the British Medical Association at its summer meeting, we have come to expect an oration that will provide food for reflection, and which, at the same time, will enable us succinctly to review the various stages by which our present knowledge has been gained. The learned address delivered by Dr. Archibald Garrod last week at Aberdeen is, in these respects, a model which future lecturers might do well to copy. In dealing with medicine from the chemical standpoint he has aptly unfolded to our gaze the wonderful possibilities that underlie the influence of chemical science, and especially of that branch known as bio-chemistry, in modifying not only our conception but also the treatment of disease. Since the early investigations of Wöhler and Liebig the progress of chemical research in its intimate relations to practical medicine has grown steadily year by year.

Starting from the first synthesis of urea, the investigations of workers in the domain of the carbon compounds has proceeded apace until the molecular structure even of the proteins themselves is no longer hidden from the analyst's ken. Fresh conquests are still being made in our knowledge of those mysterious and complex organic bodies known as enzymes, and the researches of Aberydell have opened up a new field of investigation into certain specific chemical reactions. Some of these cannot but be far-reaching in their effect upon practical therapeutics, and in one direction, at least, the use of hormones promises to be of real service in conditions where the various internal secretions are judged to be at fault. How profound may be the bio-chemical changes involved in the diverse group of affections usually comprehended under the term "disorders of metabolism" we can, in the present state of our knowledge, hardly estimate. There is one point in Dr. Garrod's address to which we would specially draw attention, and that is that, most if not all, of our therapeutic efforts are inefficient as compared with the natural powers of protection with which the body itself is endowed. Many of these mechanisms are resident in the blood, while others appear to be associated with, or dependent upon, the glandular secretions. If through a greater understanding of the relationships between the chemical composition of the foodstuffs and that of the bodily

that if an exploratory abdominal operation had been performed within a few hours of the accident the man would have been saved. It is sad to think of the number of lives lost annually from want of that skilled surgical attention such as can only be provided in a cottage hospital. There is a far greater need for these institutions in small towns and villages than for reading-rooms and libraries. It is desirable thought these may be. Where human life is at stake no effort should be spared to provide means for its preservation. Surely no more fitting monument to anybody whose name it is desired to honour could be found than a cottage hospital established in some country district where its beneficent work would continue to be done as a memorial to the name of its founder. The erection of clock-towers and statues, however beautiful, and even useful, cannot compare in practical utility with one small cottage hospital. We commend this need to all pious philanthropists and especially to those who desire to erect some memorial and who are yet undecided as to the exact form it should take.

The gradual disappearance of Shellfish and enteric fever from our midst has Enteric Fever proved one of the outstanding triumphs of modern sanitation. Indeed, in the British Medical Journal it was pointed out that there was in the past a mistaken idea that typhoid fever is primarily an enteric disease which occurs in this country. The disease was regarded as an importation from abroad. It is now known, of course, that the disease is indigenous to this country.

We are not aware that any serious accusation has been advanced against the mussel in this particular connection. Indeed, having regard to the fact that the mussel is boiled before consumption, it is presented to mankind in a condition which not only preserves the food from the consumer of living pathogenic bacilli. The mussel is invariably cooked for eating purposes, so that it is completely sterilised, and the only living microbes conveyed by it would be those acquired by contamination after cooking. The attempt to exculpate all shellfish because of the rumour that they are infected is futile and misleading. The first great distinction, so far as the spread of disease is concerned, depends on the primary fact as to whether the shellfish is cooked or uncooked. It is a matter of established scientific observation that enteric fever may be, and is, conveyed by solutions of contaminated oysters. That fact cannot be gainsaid, and a similar statement applies to other kinds of shellfish that are eaten raw. The saving grace of the kitchen saucepan converts the mussel from an active danger to an innocuous foodstuff. It can render a similar service to the oyster; but mankind has a fixed and lasting preference for the flavour of the living oyster. It is interesting to note, by the way, how the humanitarians connive at the barbarous way in which the oyster is swallowed alive. Nowadays it is the fashion of these tender-hearted emotionalists to protest against the cruelty of exterminating flies by "sticky" fly-papers. Why strain at a gnat to swallow an oyster?
secrections we shall be able the better to influence the complex processes of metabolism, we shall have gained much as practitioners. In the case of diabetes we do possess the knowledge whereby the output of sugar is largely in the hands of the medical man. With regard to the restriction or prohibition of certain articles of diet in other diseases, much responsibility rests upon the medical profession. In the twentieth century, however, we are in possession of greatly increased knowledge both from the physiological and also from the chemical side, and the help thus derived from the pathological and clinical laboratory should never be minimised nor refused by the practitioner who is anxious to do the best for his patients. Increased powers of diagnosis, as afforded by modern scientific tests, the basis of which consists of the application of some profound chemical reaction, must lead to correspondingly improved methods of treatment. By calling the attention of the medical profession, as it does, to one aspect, and that of great importance, of the science of medicine, the Address in Medicine of 1914 will be remembered as a most thoughtful and earnest discourse.

THE ADDRESS IN SURGERY AT THE ABERDEEN MEETING OF THE B.M.A. An account of the evolution of the practice of surgery since the introduction of anaesthetics and asepsis, with a vivid description of all the horrors attendant upon operations before the days of Morton, Simpson and Lister, would, we venture to think, provide the average reader with quite as much excitement as may be found within the pages of most novels or works of adventure. To say that the modern surgical operation is absolutely without risk would, perhaps, be asserting that which is not true, but that it is practically so in favourable circumstances and when undertaken by skilled hands few will be found to deny. The attainment of the highest success in surgery, however, does not lie in operative manipulations alone. As Sir John Bland-Sutton, F.R.C.S., Surgeon to the Middlesex Hospital, remarked in his stirring Address in Surgery delivered in Aberdeen last week, the surgeon is dependent upon many things—naturally upon histology; and he, like the physician, has also to acknowledge the aid given him by the findings of the clinical laboratory. The examination of the blood, for instance, is of supreme importance in determining the advisability of an operation for the removal of the spleen. Recent research in connection with the choroid plexuses must cause us to modify greatly our conceptions with regard to the function of the cerebral spinal fluid, which, according to Sir John Bland-Sutton, has been thereby transformed from that of a water-bed for the central nervous system to an actual "pool of Bethesda." Exactly upon what lines the "surgeon of the future" will work remains to be seen. To some extent he may even become an immunist, like his brother physician, but it is not unlikely that chemo-therapeutic means will influence his treatment, particularly in disorders of the nervous system. Dealing with the influence of sepsis upon malignant disease, especially of the large intestine, Sir John Bland-Sutton pointed out that the surgery of cancerous growths was greatly hindered by septic organisms. The comparison of an army of operators, dressers and nurses, all in a perfectly sterilised rig-out, to engage in the resection of a malignant growth of the colon, itself swarming with pyogenic organisms, to "killing fleas with bludgeons" may raise a smile, but nevertheless the incongruity of the situation must have often struck a critical onlooker. If some chemio-therapeutic agent, analogous to salvarsan, should ever be discovered which would be a specific for all pyogenic cocci, much of the surgeon's work would be simplified. One timely word of caution contained in the Address may be referred to—namely, the necessity for estimating all laboratory reports in the light of clinical experience. To pin one's faith to one without the other is only to court failure.

CURRENT TOPICS.

The Clinical Congress of North American Surgeons. The North American surgeons last week held their fifth Annual Clinical Congress in London. Their programme, needless to say, was full and varied from the social as well as the scientific point of view. One interesting experience was that of witnessing the skill of London surgeons in a variety of operations. Cancer cases were the chief object of study yesterday, and many skilful and instructive operations and demonstrations were seen. The visitors were extremely interested in Mr. S. G. Shattock's lecture at the Royal College of Surgeons on the origin and growth of tumours, in the course of which he propounded the theory that cancer is neither hereditary nor transmissible from one person to another, but may be transferred from one portion of the body to another. Mr. Sherren's operations for cancer at the London Hospital were spoken of in terms of high praise. In one case he removed practically the whole stomach and substituted for it the upper part of the intestine. A long series of operations performed by Mr. Spencer at Westminster Hospital, including operations for abdominal tumour, excision of cancer of the breast, jejunostomy for inoperable cancer of the cardiac half of the stomach and excision of cancer ring from bilocular stomach, were spoken of as really wonderful. It is not possible to review even briefly the field of work covered by the Congress, which will be closely followed by surgeons all over the world. To some extent the Congress has been overshadowed by the British Medical Association meeting going on in Aberdeen at the same time. In early issues our readers will have an opportunity of perusing some of the most prominent papers read at this notable gathering.

Cleverness. If a medical man is doing well we are sure to hear it said that he is clever. The users of the term are quite vague as to its significance, but they mean it as a compliment. Really it is far from that. Disease is not combated by a sophisticated cunning, nor has an assumption of breezy astuteness any
terrors for the weakest micro-organism. Our real weapon is knowledge; knowledge, and not cleverness, is the interest we receive from our toilsome grey-batter inventories. To the real man, red or white, no insult. It suggests a scariness, a puckish perversity, and a meritless excellence in mental window-dressing that we should not hanker after. We can say with equal dignity and truth that Wright knows something about vaccines, but to remark that Metchnikoff is clever at color-s is highly remiss of the word. Cleverness and application of efficiency tinged with a certain contempt. There are some people who are essentially clever—and no more. They are ingenious, quick and many-sided; but no one could call them geniuses or great. Just as almost any girl deserves the epithet pretty, while her worst enemy could not call her beautiful. The typical worker-doctor is rather a dreadful person. He knows his work, and has all the qualities of an expert salesman. His therapeuticities are down to the minute, and he is always in a hurry to use the latest cure while it is still efficacious. He usually has an eye to what people call "the main chance," and does a lot of good work of no lasting value. On the whole cleverness is a tinkling cymbal. It is nothing worth. It combines a shallow, hand-to-mouth, mentality, with three lines of Du Bartas, but it will never even change the pebbles of our puddly thought to anything at all resembling oriental pearls.

Oral Sepsis as a Cause of Death.

A distinct advance in the practical importance of oral sepsis as an established malady was last week registered by its appearance as a cause of death in the Southwark Coroner's Court. The septic condition of the teeth and sockets was the cause ascribed by Dr. Larkin for the death of Rosina Snelgrove, aged eight years. He said that she had lost permanent teeth, the sockets from which teeth had been extracted, and the gums were in a bad condition. The gums had entered the blood stream, and set up general blood-poisoning throughout the body. Dr. Larkin added that one of the most distinguished members of the medical profession died recently of precisely similar disease. In this instance the patient was a busy man, and had no time to attend to his teeth, and his illness was, like that of the deceased child, of short duration. The jury returned a verdict in accordance with the medical evidence.

Debt Certification.

We all of us have to sign debt certificates on occasion. Some of us take them calmly as of no more significance than the eternal "not fit to follow his employment" scripts that we endlessly issue. Others have, or make, time to think about them. They are occasionally depressing. The few ill-chosen words are all that is left of a good friend or a valuable chronic. They are the outward and visible sign of every little bit of hypocrisy and impurity which is within our mortal. At the annual meeting of the British Medical Association at Aberdeen, Sir Victor Horsley and others have been urging a reform in the matter of these and other certificates. We all know that at present they are almost valueless from a statistical standpoint. It may happen that debt certification is to some extent misleading, but have to be definite after death however we wavered while our patient was alive. There are many cases where we do not even fill up the certificates as we know we should. We do not wish to hurt the living so we magnify the dead. Of course, we do not put false certificates—such a thing is unthinkable—but, whilst avoiding saying that which is not, we omit to mention that which obviously is. We are encouraged to do so by the hopeless terminology to which we are confined. Sir Victor mentions that the Registrar-General's list of death include "hysteria," "neurasthenia," and "neuritis," and that in 1014 out of 500 deaths were attributed to neuritis. For "neuritis" cognoscenti read "alcohol." Venerable diseases, too, are almost always dodged. On the whole the statistics obtained from death certificates are nothing like as good as they might be, and under the present system it is too much to ask the average man to offend his patient where he need not. The solution of the difficulty is very clear. So clear that we are surprised at its suggestion. Sir Victor proposed the immediate institution of a confidential system of death certification. There is no reason against it. When one of the public is dead it is no concern of the others what terminological inexactitudes are applied to the manner of his exit.

Payment for Medical Certificates.

As inquest held last week at Sheffield throws a lurid light on the popular estimate of medical service. The friends of a deceased panel patient complained bitterly at an inquest of the conduct of a medical man in compelling payment for a death certificate. The jury returned a verdict of death from a "medical accident," i.e., disapproving of the doctor's action in charging a shilling for death certificates to such poor people simply on the ground of being private patients. This extraordinary comment illustrates somewhat vividly the attitude of the man in the street with regard to medical certification. So used is he to gratuitous service that he has come to regard this special form of assistance as a right as regards medical certificates of all kinds. It has often been pointed out in these columns that the State has exploited medical men for gratuitous service in a way that would not be tolerated in any other profession. What would the legal profession, with its multitudinous fees, say were a variety of responsibility signified documents of an absolutely indispensable legal nature to be demanded of them compulsorily without fee or reward? One of the ever-present annoyances of the honorary hospital physician or surgeon is the request for certificates by patients, who often draw sums of money on the strength of documents. Large sums do not go the lawyer without asserting that under no circumstance should any medical certificate be granted without a corresponding fee, and if the person to whom it is granted be unable to find the necessary amount, it should be paid by the body by whom the certificate is demanded, whether that be a private or a public organisation.

S.P.C.P.

The paternalism of the German Government is a thing of joy to many of us. It amuses us to think of the host of things we do that are "verbotten" to others. The idea of being fined for riding a bicycle without holding the handles gives us over to laughter which becomes Olympian when we remember that rescuers of drowning people have been indicted for bathing in forbidden waters. We feel so superior. We think that we are not as other men are, but free citizens of a free country. And we keep a look-out for instances of grandmitherly legislation on the Continent. According to the Chemist and Druggist, the Bavarian Government is keeping up the Empire's reputation. It has passed a law for the protection of plants. It forbids the pulling up of certain protected plants except by teachers and students of natural history and members of societies devoted
to the study of natural science, who may, through the instrumentality of a police permit, approach the authorised sacrifice. Of course, the definition of a student of natural history is rather difficult. So far it has been decided that chemists' apprentices are students, but the fully-qualified pharmacist is presumed to know all that there is to know, and is by no means to pluck the amaranthine flower. We wonder how the Government proposes to compete with the Boriforous infant. Is he to be made a "student of natural history," or is he merely protected by his tender years? We fear that a dare-devil race of daisy pickers will descend on Bavaria, and, with little children as accessories, will "run" protected herbage with the ease and frequency with which Irishmen import rifles. There will be trouble. Flower-pickers will have to seek a refuge before they pluck, and a course of botany and a dictionary of flowers will be adjuncts to every country ramble. Flowers will become unpopular. They will blush unseen and unsought. The seeking will be too risky. We can apostrophise with Milton: "O, fairest flower! No sooner blown but blasted."

The Sixth International Dental Congress.

This week the sixth International Dental Congress—the first ever held in this country—is being held in London under the presidency of Mr. J. Howard Mummery. About 2,000 dentists of all nationalities will attend the meetings. There will be ten sections, and among the papers read are those of Sir J. R. Godlee, upon "The General Effects upon the System which may be attributed to Toxemia of Oral Origin." Mr. Norman G. Bennett, president of the section of oral hygiene, will report on "The Effects of Dental Treatment on National Health and Physiology." Dr. J. F. Dowsley, of Boston, will describe the Forsyth Dental Infirmary for Children—an institution which has cost one million dollars, and will be opened in the autumn. An informal social meeting of the Congress took place at the Hotel Cecil on Monday evening and the Congress was formally opened by Mr. Herbert Samuel at the Central Hall, Westminster, on Tuesday, at 10 a.m. The social engagements included a reception by the Lord Mayor and Corporation at the Guildhall on Tuesday, at 8.30, an invitation banquet given by the Government on Wednesday, and a Congress banquet at the Anglo-American Exhibition on Thursday. The British Dental Association will give a reception at the Natural History Museum, South Kensington, on Thursday.

PERSONAL.

Dr. Kate Anne Platt has been appointed Principal of the new Queen Mary Medical College at Delhi.

Mr. G. Viner, M.D.Lond., F.R.C.S.Eng., has been appointed Assistant Surgeon to the Royal Westminster Ophthalmic Hospital.

Mr. A. W. Bonne, M.B., B.C.Cantab., F.R.C.S. Eng., has been appointed Obstetric Surgeon to Out-patients at St. Mary's Hospital.

Professor Paul Reclus, the eminent surgeon, who was largely instrumental in making general the use of cocaine as an anaesthetic in surgery, died in Paris on Wednesday last at the age of 67.

Professor J. C. Bose, of Calcutta, will deliver a lecture at the Royal Society of Medicine on October 30th, on "The Modification of Response in Plants under Action of Drugs," illustrated by experiments.

Dr. Fielden Briggs will preside at the annual meeting of the British Medical Graduates' Association to be held at the Earl's Court Hotel, Totham Wells, on Saturday next, August 5th, at 1.30.

The Duncan and Lalaee medals of the London School of Tropical Medicine have been won by Captain J. C. Munro, M.D. (Glasgow) of the Indian Medical Service, who passed the recent qualifying examination with distinction.

Dr. A. W. Neill, senior assistant at the Royal Edinburgh Asylum for the Insane, Edinburgh, has been appointed physician-superintendent of Warrndale Asylum, Oxford. Dr. Neill has been six and a half years on the staff of the Edinburgh Asylum.

A LARGE number of the members of the Committee of the Sunderland Royal Infirmary and friends recently gathered at the Infirmary Chapel to make a presentation to Dr. A. Bruce Low, one of the Honorary Physicians, who is leaving Sunderland for the South.

Among the distinguished foreign Surgeons present at the Congress of Clinical Surgery last week were Dr. John B. Murphy, of Chicago, Dr. Charles H. Mayo, of Rochester, Professor Schmiegelow, of Copenhagen, Professor König, of Freiburg, and many others of world-wide fame.

Prof. William Stephenson, Emeritus Professor of Midwifery in the University of Aberdeen, was presented last week with a handsome portrait of himself by Mr. C. Lindsay Smith, while another portrait by the same artist was handed over to the University to be hung in the portrait gallery.

The Madras Government has decided upon a close scientific investigation into the causation and prevention of the course of diabetes, and has appointed Dr. S. W. F. Power, a Melbourne doctor, who holds a Beit Fellowship, which carries with it £500 per annum, which will be increased by the Beit trustees to £400 per annum, while an anonymous native donor in Madras will supplement this with a similar payment, and will also pay for all the necessary equipment.

Athurst Hill, in the presence of a huge crowd, a memorial was last week unveiled as a spontaneous tribute of those among whom he did his life's work to the late Dr. I. J. Baker. The memorial bore the following inscription:—"He endeared himself to all who knew him by the uprightness of his character, his sympathy with the suffering, and especially by his kindness to the poor man. In affliction he was a spiritual adviser, he cheered the dying with his prayer and words of comfort. By his good deeds, he being dead, yet speaketh."

Of those who served in the Anglo-American Ambulance 40 years ago during those terrible days at Sedan, Paris, and Orleans, Dr. Charles F. Ryan, Glenlara, Tipperary, is one of the few survivors. He has only now received the Brevet and Decoration from the French Minister of War, bearing the seal of the Chancery of the Legion of Honour, May 7th, 1914. For his services to the wounded in the same campaign Dr. Ryan had conferred on him at the close of the war the German Military Cross of Louis H. of Bavaria, and also the Bronze Cross of the French Ambulance Society.
CLINICAL LECTURE
ON
ABDOMINAL TUBERCULOSIS. (a)

By EDMUND CAUTLEY, M.D.Cantab., F.R.C.P.Lond.,
Senior Physician in the Metropolitan Hospital and to the Belgrave Hospital for Children.

ABDOMINAL tuberculosis occurs at all ages, and is most common in children and young adults. About half the cases under the age of 15 years are from three to six years old. It may occur in the first year of life, but is comparatively rare before the third year, and very rarely as part of an acute military tuberculosis. Boys and girls are equally susceptible. The glands, intestines, or peritoneum may be affected, alone or in varying combinations.

Ulcration of the intestines is the least common type. It usually begins near the ileo-caecal valve, and occasionally is very extensive and distributed through both the small and large intestine. Anorexia and wasting are the earliest symptoms. Diarrhoea depends on the extent of the ulceration and on secondary ileo-colitis, the stools becoming offensive and containing mucus, pus, and sometimes blood. In a girl, aged 4 years, who had been ill for eleven months, the above symptoms were present, together with colicky abdominal pain, and enlargement of the liver. Nothing abnormal could be felt in the abdomen. After death numerous ulcers, many completely encircling the gut, were found in the small intestine; extensive ulceration of the caecum; and two large ulcers in the colon, which had given rise to considerable stricture. At the bases of the ulcers there was a little adherent peritonitis, matting together adjacent coils of gut. No caseous mesenteric or mediastinal glands were found, a notable point in view of the opinions held on the introduction of the bacillus via the alimentary tract. The primary focus was a caseous nodule in the upper lobe of the left lung. Constipation is not infrequent in these cases, although there may be extensive ulceration, and reflex vomiting is not uncommon.

Tuberculosis of the mesenteric glands is a much more frequent condition, often present without giving rise to symptoms and only recognised after death from some other disease. The name "tubes mesenterici" ought to be reserved for cases of limited type. And yet it is difficult to say whether a gland exists without obvious pathological change or ill-health, not being suspected until the peritonitis is involved. Sometimes enlarged glands are discovered during routine examination of the abdomen. The common situations are to the right of the umbilicus, above and below its horizontal level, and to the left of and below the umbilicus. As a rule the glands are hard, localised and movable. They must be distinguished from faeces, caseous masses, tumours, chronic appendicitis and subacute intussusception. In a very healthy girl of 15 years, who had lived on the East Coast all her life, there was found a definite lump in the right iliac region a little above the usual level of an appendix abscess. She had had a history of two or three attacks of "appendicitis," the last one about a fortnight previously. At the operation this lump was found to be due to tuberculous glands in such an advanced stage of degeneration that one broke down during handling. Both the glands and the appendix were removed, the latter showing marked evidence of old and recent inflammation, and recovery was uneventful. Had no operation been done it is practically certain that the softened gland would have required and caused caseous peritonitis. This is one of the sequelae of caseous mesenteric glands. More commonly they cause, dry up and calcify, giving rise to no further trouble. Sometimes they set up adhesive peritonitis. Many years ago I saw a man, who had previously been in hospital for ascites from which he had made a good recovery. He was feverish and had general bronchitis. I regarded the case as one of general tuberculosis in spite of the history of ascites and of heavy drinking. This was verified after death. In the abdomen were found two cheesy tuberculous masses and generalised adhesions. The liver gave no indication of alcoholic habits, and I had no doubt that the previous ascites was the result of tuberculous peritonitis.

In the diagnosis of tuberculous mesenteric glands importance may be attached to such signs as general ill-health, slight fever, anorexia, constipation, colicky pains and hepatic enlargement. Many of these symptoms are also present in intestinal dyspepsia, to which I shall refer later.

Acute military tuberculous of the peritonum may be a part of a general infection and give rise to no special localising signs. Sometimes acute peritonitis is due to acute tuberculosis of the peritonum alone and is indistinguishable from other types of infection. Thus a boy, aged 12 years old, was seized with vomiting and abdominal pain. On the third day he was almost moribund from toxemia and collapse, with a distended and tender belly. I regarded the case as one of acute pneumococcal peritonitis but, when the abdomen was opened, the peritonum was found studded with grey and yellow miliary tubercles. He made an uneventful recovery. Sometimes the acute outbreak occurs round the caecum and simulates appendicitis.

In distinguishing acute tuberculous peritonitis from other types we have certain facts of some assistance. Thus, pneumococcal peritonitis is more common in girls than boys and in half the cases is secondary. The onset is generally sudden, the temperature high, diarrhoea often present, perhaps hemoptysis, and leucocytosis is considerable. Sometimes the peritonitis is diffuse, severe, persistent and rapidly fatal. More often it quietens down in a few days, but diarrhoea persists, meteorism develops and an abscess forms. It used to be thought that an abdominal abscess discharging at the navel was almost invariably tuberculous. I believe such an abscess is often pneumococcal, and in one case I found it due to diverticulitis, resulting in fecal fistula. A pneumococcal abscess may be encysted, forming an abdominal empyema, in any part of the abdomen, usually below the level of the navel and generally discharging through the navel in 4-6 weeks. It may perforate the stomach, vagina or bladder.

Pneumococcal peritonitis is practically limited to the female sex, being due to an ascending infection.
via the Fallopian tubes. It is rare before four years of age, and vulvo-vaginitis is almost invariably present. In a localised form it causes salpingitis, which can be recognised on rectal examination. Fever, frequent micturition, alternating constipation and diarrhoea, and the usual signs of peritonitis, perhaps most marked in the lower segment of the abdomen, are present. Acute symptoms subside rapidly, for the vitality of the organism in the cellular tissues is small.

In new-born babies acute peritonitis is generally streptococcical in origin. At all ages appendicitis and perforative lesions must be carefully excluded. And the illness must be differentiated from typhoid fever, scarlet fever, and peritonitis secondary to tuberculosis, appendicitis, subacute peritonitis, suppurative peritonitis, external peritonitis, and abscesses are rather sequels of other types of peritonitis of the abdomen than primary conditions. They must be diagnosed from other cysts and tumours. In women the truth may be only arrived at by exploratory laparotomy.

**Prognosis.**—The outlook in tuberculosis of the abdomen depends on social position, age, sex, the type of the disease and partly on the extent. As long as it is limited to the abdomen the prognosis is fairly good, even in the caseous type and still more so in the adhesive and ascitic forms. The acute stage of the ascitic type lasts 4-8 weeks or more, and it then becomes adhesive. The adhesive variety is rarely fatal though it may last for a year or more. Sometimes in cases of intestinal obstruction, and general dissemination may occur. In one such case peritonitis and abdominal distension were severe. On opening the abdomen constricting bands were found and divided, but a few days later death ensued from tuberculous meningitis; and I think the vomiting and constipation were really due to this and not to obstruction. In a few cases of caseous peritonitis, in which all the intestines are matted together, it is quite common for the bowels to act normally. The chief bad signs are dissemination, intestinal ulceration, lung infection, pleurisy, obstruction, caseous masses, localised suppuration, and cutaneous haemorrhages; exacerbations with fever, vomiting, diarrhoea and rapid wasting. Relapses are not infrequent.

**In treatment,** primary attention must be paid to hygiene, nursing and diet. Bed is essential during acute stages and for a fortnight at least after fever has subsided. It is better to keep these patients under your own charge, if a decent home and nursing are available, rather than dismiss them to the country or seaside. Parents and relatives are quite to think fresh air is the all important element in treatment, whereas much more depends on careful feeding, nursing and medical treatment.

**Feed the patient on milk, peptonised if necessary, Benger's Food, for in its preparation partial digestion takes place, meat jellies, beef tea, beaten-up eggs, vegetable soups or fruit juices, raw bread, and milk. Avoid boiling, and first give bread or rusk and milk, during the acute stages, and for some time longer unless the stools are normal in character. Then add to the diet chicken or veal cream; pounded-up undercooked meat and mashed potato; fish and minced meat. Avoid all fermentative foods. Malted foods, malt sugar, and all other foods generally perishable. The diet must be highly nutritious and easily digestible, containing little waste matter. Milk must be given in moderation and is often unsuitable, forming large indigestible curds. If so, it must be diluted or partially predigested. Or some of the malted milks and dried milk foods can be given.**

Local and general measures for acute tuberculous peritonitis are those suitable for peritonitis from any cause—e.g., bandaging the abdomen for with absolute certainty that there is no tuberculous, for both conditions may be present in the same child, and the intestinal dyspepsia may be secondary to the tuberculosis. A negative von Pirquet reaction may be of some assistance. Yet the differential diagnosis is of grave importance, seeing that the treatment suitable for tuberculous disease often exaggerates the signs of intestinal dyspepsia, codliver oil and seaside air rarely being suitable. The "Coeliac Disease, or Belly Affection," occurs in infants under 2 years and is rare after 4 years of age, and is characterised by abdominal distension and white stools. It is also often mistaken for abdominal tuberculosis.
support, keeping pressure off, and applying bran poultices or ice-bags if they can be borne. Incision and drainage is necessary in a few cases. In the chronic ascitic type, and especially if there is any suspicion of purulent effusion, it is advisable to open the abdomen. Paracentesis is dangerous, for the gut may be adherent to the abdominal wall. Surgical measures are not as warmly advocated now as they were few years ago. Formerly the prognosis of this disease was regarded as very grave. Then it was found that in cases in which the abdomen was opened through a mistaken diagnosis of the condition as one of renal sarcoma, pyosalpinx, ovarian cyst, etc., recovery took place. It was consequently argued that the beneficial result was due to the operation, by letting in air or oxygen, by evacuating toxic fluids, or by altering the tension in the abdomen. Now it is realised that the prognosis is fairly good and that, apart from surgical intervention, patients make excellent recoveries.

The only sure operation for the removal of large ascitic effusions, which do not clear up under ordinary treatment, and for the evacuation of pus. If toxic ascitic fluid is let out it is rapidly replaced by a non-toxic fresh effusion, with considerable benefit. The removal of caseous masses is too speculative a procedure to recommend. If, on opening the abdomen for any other cause, breaking down tuberculous glands are discovered, I think they should be removed, although there is a little risk of setting up dissemination.

For the treatment of ordinary chronic cases I rely on inunction of the abdomen with a mixture of equal parts of belladonna and blue ointments and olive oil, spread on lint and bandaged on. Recently I have used iodex, an ointment containing 5 per cent. of iodine, with good effect. X-rays are injurious as they induce leucopenia. Internally I give iodide of potash, gr. 1/24, t.d.s., or tannin, or with codliver oil and malt. Cresoate, guaiacol and styracol are all useful for diarrhoea and tympanites. Bismuth and opium may be given for diarrhoea if there is little or no meteorism. It is usually due to erroneous diet or to ulceration. For constipation rely on codliver oil and malt, and careful feeding. If drugs are needed give calomel, sulphate of soda, or magnesium, or emetate, oil or glycerine. During convalescence, Nourry's wine containing iodine, gr. 1-5, and tannin, gr. 3, per oz., in doses of dr. i-v, with meals twice a day may be given.

Tuberculin has not proved in my hands of any certain value, and in some cases it has appeared distinctly injurious. I am convinced that, under careful treatment, the outlook is distinctly good, but that treatment must be persisted in steadily for a long time, and much attention given to minutiae, and especially to the digestibility and suitable character of diet.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Prof. Ed. Lalvel, M.D., of the Faculty of Medicine of Paris Subject: "Grave Surgical Decisions in Daily Practice."

ORIGINAL PAPERS.

RESULTS OF OPERATION (LARYNGO-FISSURE) FOR INTRINSIC CANCER OF THE LARYNX.

By PROFESSOR E. SCHMIEGEL, Copenhält.

LADIES AND GENTLEMEN.—Surgical treatment of intralaryngeal cancer gives exceedingly good results, especially when compared with those obtainable by surgical treatment of cancer in other internal organs.

On examining this fact we find it to be due to the peculiar manner in which intrinsic cancer of the larynx originates and spreads, as was originally pointed out by my friend Sir Felix Semon. It would be interesting historically to consider the development of the pathology, diagnosis and treatment of intrinsic cancer of the larynx, but lack of time forbids me doing so. You, no doubt, will permit me to state here in London, speaking to an assembly of prominent American and English surgeons, that, in my opinion, the whole of our present knowledge of the diagnosis and treatment of this disease is founded on the works of Semon and Batlin, who, towards the end of last century, entirely revolutionised our views with regard to the malignancy of intralaryngeal cancer. Before their day the surgical treatment of this disease had always been regarded as almost hopeless, but Semon showed us that the chief reason of this was, that the disease was always diagnosed too late, so that it was too far advanced to give any good operative result.

Having further learnt that intralaryngeal cancer in the great majority of cases appears as a primary cancer of the vocal cord, and therefore soon causes hoarseness, we have means of recognising the disease at an early stage of its development, while still limited to the vocal cord, and so of probable radical cure by removing the diseased vocal cord through a laryngoscope.

To illustrate the frequency of primary cancer of the vocal cord I wish to draw your attention to this table of 66 cases of intralaryngeal cancer which have come under my observation:—

<table>
<thead>
<tr>
<th>Table A.—Primary Seat of Intralaryngeal Cancer</th>

</tr>
</tbody>
</table>

In the first 18 cases the primary site of the disease could not be localised as the tumour had extended too far into the larynx when first observed.

The table clearly shows that cancer of the interior of the larynx in by far the majority of cases originates as a growth of one vocal cord, generally in the central part of it, and that it can therefore be radically removed. If the disease, however, has extended to the anterior commissure the prognosis becomes more serious, as under these circumstances the thyrotomy cuts through the growth and may possibly be followed by a recurrence.

Those cancers of the larynx which do not paralyse the vocal cords have, on the contrary, a bad prognosis; firstly, because they very often are not discovered and taken in hand until they have spread so far that there is no possibility of a radical cure by means of a laryngoscope; secondly, because the extra-cordal-cancers are generally of a more soft medullary character, growing quickly and with greater tendency to involvement of the neighbouring lymphatic glands.
The only exceptions to this are the pedunculated adeno-carci-nomas which spring from the aryteno-epiglottic folds. Of these I have seen three cases which had a relatively good prognosis and could be treated endolaryngeally with favourable results.

Having made the diagnosis by means of laryngoscopic inspection, supported by microscopic examination of a portion removed through the mouth, one has to remove the growth as soon as possible by means of a laryngotomy.

This operation should be performed as indicated by Butlin and Semon who about 1890 inaugurated this treatment and proved that this comparatively safe operation was sufficient, if only performed soon enough.

I myself, chiefly following their instructions, have operated in the following manner:

The operation is always performed under general anesthesia. I begin with morphinum ether and make a low tracheotomy. Hann's Tampon-cannula is introduced and the narcosis is continued with chloroform. The thyroid cartilage having been divided and the interior of the larynx opened, I fill the pharynx with sterilised gauze introduced from below through the split larynx in order to prevent the saliva from descending and interfering with the scene of action. According to Semon the larynx is packed with gauze soaked in a 10 per cent. solution of cocaine, to which I add a few drops of a 1 per mille solution of adrenalin in order to make the mucous membrane of the larynx anaesthetic and bloodless. Then the neoplasia, together with the whole diseased vocal cord, is removed by means of knife and scissors.

All the diseased area having been removed and the bleeding stopped, we formerly filled the larynx with a tampon of Iodoform gauze, but after Butlin taught us to give up tamponading and to close the thyrotomy wound at once, the results of operation have been much better.

The patients are now able to swallow on the day of operation and can leave their bed a few days later. This, of course, is of the greatest importance in preventing complications in the lungs, specially in elderly people. My two eldest patients, respectively 71 and 74 years old, were able to leave their bed on the second day, and they are both alive and well, now at the age of 80 and 76 years.

Thyrotomy could only be performed in 33 of my cases treated up to 1912 as shown in the following table:

<table>

</tbody>
</table>

The result of these 33 thyrotomies was that 28 patients survived the operation whilst 5 died from pneumonia, due chiefly to post-operative hemorrhage.

Amongst the 28 patients recurrence took place in 10 cases, whilst 18 are alive and well. These 18 had the carcinoma entirely limited to the vocal cord and the diagnosis was made at an early period of the disease—with only two exceptions. The first of these was a man aged 44 years (see Table D, No. 11), who had a cancer of the posterior wall of the larynx, and whom I was able to follow for three years after the operation, when I lost sight of him. The second was a man, aged 28, suffering from an epitheliosis of the left ventricular band, anterior commissure and the anterior part of the right ventricular band. This patient I operated on 14 years ago, and since then he has been on an expedition to the North Pole and is still alive and well.

The last 4 patients were operated in 1912 and have therefore only been under observation for about 2 years since the operation. But they were all cases of quite limited epitheliosis of the vocal cord and were operated so early that there is not much chance of recurrence.

Patient No. 7, a man aged 61, was operated in 1905 for a cancer of the vocal cord. During the following 7 years his larynx remained perfectly healthy, but he now has a quickly growing cancer in the throat requiring tracheotomy. Ought this to be considered as a recurrence or as an accidental cancerous infection of a larynx which has kept perfectly healthy for 7 years after operation? Personally I am inclined to look upon it as an accidental reinfection. In all the other cases of recurrence this took place within a year after the thyrotomy.

The functional result was exceedingly good in all cases. The voice was strong, generally sonorous, but in a few cases hoarse. The man aged 71 was operated on in 1905; I saw him last in 1913, he was then 79 years old and had a strong, healthy voice.

A clergyman aged 55 who was operated in 1866 fulfilled his duties for 8 years and preached every Sunday in two churches.

The two men, aged respectively 66 and 67 years, who were operated in 1912 are able to make speeches to large assemblies with a comparatively clear voice.

So as to get a broader basis of judgment as to the results of thyrotomy in cases of intrinsic cancer of the larynx I have combined in the following table my own experiences and those of F. Semon, Chiari and St. Clair Thomson. The results are as follows:

You see herefrom that of 92 operated patients 52 (= 56.5 per cent.) were cured for more than one year after the operation.

(1) Secondary operation of removal of larynx and now alive 5 years later.
(2) Died from other causes 15 months after laryngofissure.
THE SUTURE OF THE LEVATOR ANI MUSCLE IN PERINEORRHAPY OPERATIONS. (a)

By HENRY JELLETT, M.D. DUB., F.R.C.P.,
Master of the Rotunda Hospital, Dublin.

The selection of a subject which is suitable for discussion before this Congress is a matter of some difficulty, since matters which are of the highest interest to the general surgeon are not so necessarily to the general surgeon. At the same time, it is more likely that a specialist will be of interest to his hearers if he deals with a subject which for the moment is of interest to himself, and so I have selected an essentially gynaecological subject.

There are other reasons why I have selected this particular gynaecological subject. In the first place, although it is a generally accepted fact that the support furnished by the levator ani muscle, either with or without its investing fascia, is essential to the pelvic organs, none of the older methods of perineorrhaphy provides a means of such suture. In the second place, it is surprising how many of the best known modern gynaecologists are content to continue to practise these operations, because, and this is my third reason for my choice of subject, they consider, and in fact they are directly told that suture of the muscle, however essential it may be, is a difficult operation, and one not devoid of danger. I do not think that I need spend much time in defending my first reason, Lawson Tait's, Martin's, Hegar's, and Kelly's original operations all neglect to take the levator ani muscle into consideration. It is true that occasionally they may result in causing its suture, but this only occurs when the muscle is not far retracted, while when it is retracted, and when its suture is more imperative, they fail. As to my second reason, any gynaecologist who says that he is not aware that it is right, as well as I, and he can say whether his third reason is not also right, and whether the omission to suture the muscle is not the result of the idea that such suture is difficult,

Doderlein and Kronig, in the latest edition of their work on gynaecological operations, and Martin of the University of Kiel, in an important communication to the gynaecological surgeons, have strongly advocated the use of the levator ani muscle and fascia, and are largely responsible for perpetuating this idea. They, however, are apparently strong advocates of suture, and it seems a pity that their writings should rather tend to complicate the operation, and so to prevent its universal adoption.

I have practised systematic suture of the levator ani muscle for the past six or seven years, and I think I may say that I have used the muscle in every case in which I have performed perineorrhaphy during this period except where the muscle was absent or atrophied, but when I stated this fact at a discussion on the subject, I was told that I never sutured it. The reasons given for this statement were first, that Kronig showed how easy it was to suture it; secondly, that I did not regard the levator ani, and secondly, that Martin said that suture of the levator was a difficult operation involving an extensive dissection, whereas my operation was a simple and easy one. It is just because it is simple and easy that I take up the time of the Society with this paper, in which I desire to show, that, with the method of the point of union of the pubic and ischiad ramus, there are no anatomical difficulties in the way of muscle suture, and secondly, that there are no practical difficulties.

The structures which are involved in a perineorrhaphy operation from without inwards are as follows:

(1) Skin.
(2) Subcutaneous fascia.
(3) The constrictor vagina muscles, and the superficial transversus perinei muscle.
(4) The deep transversus perinei muscle.
(5) The levator ani muscle.
(6) The vaginal mucous membrane.

We may at once dismiss a number of these structures from consideration because their suture is a matter of surgical ease. A more careful regard of the subject has been devised. These are the skin and superficial fascia, the constrictor vagina and superficial transversus perinei muscle, and the vaginal mucous membrane. This leaves two muscles for consideration—the deep transversus perinei and the levator ani. The deep transversus perinei muscle rises from the pubic and ischiad ramus. As it approaches the middle line, it spreads out. A few of the most anterior fibres pass to the anterior wall of the vagina, and lie behind the urethra. The remaining fibres pass behind the vagina to the central point of the perineum (Thompson). A great deal of importance has been attached to this muscle by Kronig, who apparently considers it a structure which is sufficiently long both to afford support in cases of slight prolapse, and to be mistaken for the levator ani. In his description of perineorrhaphy as performed in cases of slight prolapse, he says that after the initial incision the fibres of the deep transversus can be seen, and their course demonstrated by traction. They lie over the pubo-rectal part of the levator muscle, and have often been mistaken for the latter.

"To prevent this mistake the diverging muscle bundles should be followed to the sides, the deep transversus perinei passes towards the ischiad tuberosity, while the levator ani passes forwards towards the pubis." He then goes on to show how this muscle can be sutured.

There are two points raised here with which I must deal at once. The first is that Kronig regards the deep transversus perinei as a structure which can not only be easily found, but which is strong enough to be used to reconstitute the pelvic floor. I should hesitate to say in the face of so eminent a surgeon the following words: "I do not regard this statement as correct, even though anatomists and one's own personal experience showed that they are incorrect, was it not that on an earlier page of the same article, Kronig himself places the import-
idence of the deep transversus perinei before us in a true light. Here Krönig definitely states that the deep transversus perinei in nullipare is as thick as the little finger, while in multipare, and the uterus prolonged, it is reduced to mere strands of muscle fibre. It is thus apparently possible that when one comes to perform a perineorrhaphy in the muscular nullipara, one may be able to find and to derive help from the deep transversus perinei.

The second point concerns the anatomy of the muscle, and that there is something radically wrong in Krönig's statements about it is shown by comparing his anatomical drawing of the deep transversus perinei with his drawing of the same muscle as exposed during operation. (Slides). It is difficult to conceive how a muscle possessing the anatomical relations shown in the first drawing could come into one position in which it is said by Krönig to be placed, while in the second drawing it is placed in such an attitude as to be out of all possible range of action as a muscle.

The part of the levator ani with which the gynaecologist is concerned rises from the back of the body of the pubis, along an oblique line which extends from the lowest limit of the symphysis upwards and outwards to the obturator canal, and also from the obturator fascia for a limited extent (Those backwardly to insert into the upper half of the vagina, about half an inch above the hymen, and then similarly at the side of the rectum to be inserted mainly into a median raphe between the anus and the tip of the coccyx. It has also apparently a slight insertion into the vaginal and rectal walls at the point at which it crosses the latter, and it is difficult to meet this part of the opposite side in the central point of the perineum. It has not, however, any considerable insertion into the perineum, and the union of its fibres which are produced in this region by operation is purely artificial, and in no way a reproduction of the condition of affairs existing before the operation. In the position in which it is seen high into the vagina of a nullipara, and then drawn down along one lateral wall exerting a slight outward pressure, it comes to rest on the upper surface of the muscle, the extent and relations of which can be readily ascertained. It will also be obvious that the main mass of the muscle pass backwards at each side of the pelvic canal in contact with a distinct separation between them. If a similar separation is made in a case of fairly extensive perineal laceration, the lateral masses of the muscle will still be felt, but the gap between them will be greatly increased, in consequence of their outward retraction. Further, if a similar examination is made in the case of a patient in whom suture of the muscle has been carried out, the upper border of the lateral masses will be obvious, and so will the fact that they actually meet one another in the middle line throughout the whole antero-posterior depth of the perineum. Lastly, if the muscle is exposed from below by the method which will be described later, and if it is caught in a forceps and drawn down, the finger in the vagina readily proves that the forceps is holding the muscle which forms the pelvic floor and no other. For this reason I have no hesitation in saying that it is impossible for Krönig to have, with the details of the operation to mistake the muscle for any other structure in the pelvic floor. Just as the possibility of mistaking a practically non-existent structure for the levator ani has been exaggerated, so has the difficulty of the operation and the extent of the dissection required. I cannot understand this latter exaggeration of the case that it exists, I quote a sentence from an article by Martin of Bunn's Klinic, in which he describes an operation that appears to have very few points of difference from the one I habitually practise. Martin writes:—If the fibres of the levator ani are to be brought into view, the connection between the pelvic fascia and the superficial diaphragmatic fascia must be divided. This, however, means a very deep dissection, and causes haemorrhage if a broad strip of the pubo-rectalis is laid bare, because one is working in the neighbourhood of the recto-vaginal venous plexus. When the muscle is approximated, the needle frequently pierces this plexus, and so causes emboli as Bunn has described.

I have criticised adversely from the standpoint of my own experience both Krönig's and Martin's efforts to attach difficulty and danger to the routine suture of the levator ani. There is, however, one disadvantage of a slight character to which they both allude, and which I think requires attention. I refer to the fact that the opposition of the muscle and its separate suture leads to the formation of dead spaces between the vaginal mucous membrane and the upper surface of the muscle. If these spaces are allowed to remain in a condition in which blood can accumulate in them, infection of the clot from the rectum is very liable to occur, and to convert the haematoma into a true abscess. Here, however, a very simple and essential method which I shall presently describe, of obliterating such spaces, and so of preventing the accumulation of blood in them.

Before describing the operation which I have evolved for myself, and which I habitually practise, I would like to say that the method of operation I should like to follow is the one which Krönig describes, for chronic lacerations for chronic lacerations have been performed at the Rotunda Hospital, in practically every one of which the levator ani has been sutured. In an occasional case, union of the muscle has been complete, in other cases—particularly in the early ones—a haematoma has formed, but there has never been a death, or even a patient whose condition gave rise to anxiety owing to the occurrence of emboli from punctured venous plexuses.

I should also like to say, in case the slides of the operation appear familiar to some of you, that the drawings from which they were made were just two and a half years ago for me from my operations, and that I take no responsibility for their resemblance to any other illustrations which have been drawn and have appeared since. Within the last two months I have had certain anatomical details in them slightly altered, as the levator muscle was placed at too superficial a level.
The essential features of the operation are as follows:—

1. The careful dissection of the necessary amount of vaginal mucous membrane of the rectum.

2. The exposure and suture of the separated levator ani muscles.

3. The careful approximation of the cut edges of the vaginal mucous membrane, in such a manner as to leave no projection or redundancy.

The operation is carried out as follows: The extent of the perineal tear is carefully determined, and its anterior edges are marked out by bullet forceps as shown. A third bullet forceps is applied to the perineal skin just behind the posterior edge of the tear. A pair of the right-handed pair of the lever and is by palpation through the mucous membrane of the vagina. An incision is then made from side to side along the line of junction of the skin and the vaginal mucous membrane. This incision cuts through the skin and any underlying scar tissue. A flap of vaginal wall is then dissected up to the underlying rectum. At its lowest point it is firmly held to the retractor and the sphincter ani by cicatricial bands, the result of the old cicatricial healing. As soon, however, as these have been cut through, the separation of the remainder of the flap by blunt dissection is an easy matter. The easiest method of dividing these bands with the scissors so as to avoid injuring the rectal wall or the vaginal mucous membrane is to make an incision down the side of the perineum, thus forming a triangular space, which is bounded laterally by the remains of the superficial vaginal and perineal muscles, and at a deeper level by the pubo-coccygeal fibres of the levator ani muscle while its floor is formed by the rectum. It is then an easy matter to catch the edges of the flap with clip forceps or dissecting forceps, and to divide them downwards until they meet in the middle line. If the separation and atrophy of the muscle is marked, then it may not be possible to draw the edges down sufficiently, but, in the great majority of cases, they can be brought into view as shown. Three or four interrupted sutures of catgut are then passed through the edges of the flap, and the sutures are then approximated in the middle line; for the present, however, they are left untied. The next step is to trim the vaginal flap into proper shape, so that, when the operation is complete, there may be no redundancy. The usual line of incision is shown, and the effect of the removal of redundant tissue. The cut edges of the flap are then brought together by a continuous catgut suture passed from above downwards, and ending at the vulvar orifice. This being done, the catgut sutures in the levator muscle may be tied. The last step consists in the introduction of silkworm gut sutures passed so as to close the skin edges of the perineal wound. These sutures are passed from side to side, and traverse the skin, the subcutaneous fat, the intermuscular septum, the muscular, and also the levator muscle so as to supplement the buried catgut sutures. The method of inserting them will be clearly seen in the illustration.

Sometimes during this procedure there may be haemorrhage from the hemorrhoidal vessels. Any bleeding vessel, if of large size, should be ligated by a clip, and tied, but, as a rule, the best method of stopping bleeding is by preceding rapidly with the operation.

I have mentioned the tendency there is to the formation of dead spaces between the vaginal mucous membrane and the upper surface of the levator ani, and, when necessary, of freeing the vaginal flap and the separation of the edges of the muscle from the sides of the vagina. The final step of the operation is directed towards the prevention of the accumulation of blood in such spaces, and is, in my opinion, an essential precaution. It consists in the firm plugging of the vagina with iodiform gauze. The plug must be applied most carefully, so as to avoid injury to the vaginal sutures, and in such a manner that it lies wholly above the muscle with the exception of the ends which hang out through the vulvar opening. It is quite impossible to introduce it satisfactorily by merely pushing it upwards through the narrowed orifice. The reconstituted perineum must be drawn carefully backwards by means of a narrow retractor passed into the vagina, so as to lie above the levator muscle, the retractor which I use for the purpose is known as Daven's vaginal retractor, and is made by Collin of Paris. Though intended as an anterior retractor, it possesses a blade which is set at just the correct angle to the handle to allow it to pull back the posterior vaginal wall and the muscle in the manner required for the insertion of the plug. By means of it it is possible to introduce a strip of gauze to such an extent that it becomes some five to six yards in length, in such a manner that, while the gauze expands the upper part of the vagina and keeps the posterior vaginal wall in close contact with the sutured muscle, it throws little or no strain on the sutured mucous membrane which lies below it.

I have described this step in detail because I attach very great importance to it, and because it is impossible to carry it out satisfactorily without a suitable appliance such as the retractor I mention.

The advantages of the foregoing operation are its ease and its rapidity. In an ordinary uncomplicated case it can be finished in less than ten minutes, and in the cases examined here in only a few minutes. The advantages of positive suture of the levator ani in perineorrhaphy operations are so obvious that they do not require to be mentioned, but to emphasise them I show four diagrams, which I constructed with fair accuracy from two cases of perineorrhaphy. The first pair of these show the condition of the perineum and the relations of the rectum and the vagina in a patient on whom I operated, and the other pair of the other perineorrhaphy operations had been performed. The external result was apparently excellent, but on passing the finger into the vagina, the perineum was found to consist of a thin shelf formed of skin and superficial fascia. A little further examination showed that the lateral masses of the levator ani muscle were retracted, but widely separated, lying in the position into which they had retracted as a result of the original laceration. The second pair of diagrams show the same points in a patient in whom the muscles had been suared and the operation carried out as I have described. The difference in the condition of the perineal body in these two cases is evident, and examination showed that the lateral masses of the levator met in the middle line. In fact, the shape of the perineum is practically that found in the nullipara, and the only difference is that the inner muscle edges meet in the middle line instead of merely sending a few fibres into the central tendon of the perineum.

I should like to sum up my conclusions briefly:—

1. Routine suture of the levator ani is an essential part of perineorrhaphy.

2. Routine suture is always practicable, except when the muscle is wanting owing to atrophy after injury. Such absence is very rare, and, when it occurs, it is impossible to reconstitute the perineum satisfactorily.

3. The exposure and suture of the levator ani is neither difficult nor dangerous.
THE RELATIONS OF CHEMISTRY TO MEDICINE. (a)

BY ARCHIBALD E. GARKOD, M.A., M.D.,
F.R.C.P., F.R.S.
Physician to St. Bartholomew's Hospital.

So complex is modern medicine, and so diverse are its aspects, that we cannot hope to attain to any comprehensive notion thereof if we regard it from any single point of view. We need to adopt, on the one hand, the standpoint of the human organism engaged in its unceasing struggle to ward off the assaults of disease, and, on the other hand, that of the agents of disease which are as incessantly striving to gain a foothold. The clinical worker whose task it is to diagnose the nature and seat of the malady, and to intervene in the interests of the patient, has his special outlook; and the pathologist, who studies the havoc worked by disease, has his. Again, we may contemplate the human organism as a whole, or as a complex structure built up of diverse organs and tissues, each with its assigned functions, or once again, as a nation of cell units endowed with manifold activities. Lastly, we have to picture each individual cell as a congeries of chemical molecules which are being continually pieced together and broken down by the agency of intracellular enzymes. Thus physician and physiologist, physiologist and pathologist, biologist, bacteriologist, and chemist, each looks out upon the field of medicine from his own standpoint, and to each it wears a different aspect. Only by the combination of the several mental pictures can a stereoscopic presentation be obtained.

Many of the early chemists were practitioners of medicine, and from the days of that eccentric genius who assumed the name of Paracelsus, and of van Helmont, the father of physiological chemistry, down to the earlier years of the nineteenth century, the chemical outlook was that most widely adopted by medical men. But in those earlier days chemistry itself was in far too embryonic a stage to lend much aid to the elucidation of the problems of disease, and, as time went on, the chemical outlook was abandoned to a large extent in favour of that afforded by the rapidly advancing study of morbid anatomy. Throughout the greater part of the last century morbid anatomy and histology held the field unchallenged; and they were justly entitled to do so in view of the progress made in the macroscopic and microscopic study of diseased structures, upon which was reared an imposing edifice of cellular pathology.

THE STUDY OF BIOCHEMISTRY.

Biochemistry presents itself under two aspects: a static, which is concerned with the study of chemical structure, and a dynamic, which deals with the chemical changes of which the living tissues are the seats. Thus may wander amongst the streets of some deserted city of the past, may study the fabric of its buildings—the stones, bricks, and mortar employed in their construction, and in this way may gain some knowledge of the uses for which the several buildings were designed. Just so the anatomist investigates the structure of the organs of the dead body, and the chemist, by his analyses, gains a minute insight into the molecular groupings of the materials of which its tissues are composed. Even in the dead city all is not still and at rest. The ancient walls are subject to weathering and decay, and gradually crumble under the influence of air and rain. Yet other changes are wrought by lowly forms of animal and vegetable life, which undermine the ruins and, in the end, bring about their downfall. So, too, in the dead body, destructive agencies are constantly at work until the dust returns to its dust again. Once more we may tread the streets of a city of to-day, may watch the movements of the crowds as they part the gathering and dispersal of groups of people. We may study the arrangements for the disposal of waste products, the ways in which food supplies are brought in, dealt with, and distributed. Or we may investigate the police arrangements, the sanitary services, and the various devices resorted to by the community for its protection.

The study of the human organism on such lines is the province of physiology, and it is to designate the sum total of the manifold chemical processes in action within the living organism, and which constitute its life, that the term 'metabolism' is employed.

But the chemical physiologist is far from sharing the opportunities afforded to our wayfarer. He is hardly permitted to set foot within the walls of the living city, and on that account his investigations are carried on under serious disadvantage. Determination of the balance of intake and output affords clear indication of the grosser chemical interchanges in the body, but the study of the intermediate stages is a far more difficult task, and only now are we beginning to gain an insight into the details of metabolism. Such knowledge of these details as we have acquired is largely based upon circumstantial rather than upon direct evidence. But here, as in other fields, pathology lends a double aid to physiology, and Nature's experiments and her mistakes afford, to him who is able to read them aright, insight into the methods of her orderly working.

THE ROLE OF ENZYMES.

It is believed that metabolic changes are wrought by specialised enzymes, many, if not all, of which are capable of reversed action. We may picture to ourselves the individual protein traction as handed on from enzyme to enzyme, each responsible for some particular step in the series of changes, until the series is completed and the specific protein has been built up, or the final excretory product has been reached. Thus are produced numbers of intermediate products which are subjected to further changes as soon as they come into existence, and which call to mind a moving staircase rather than a flight of steps. Most of these intermediate products are never met with in an examination of the excreta, or only when the further transformations which they naturally undergo are in some way arrested. Regarded from the chemical standpoint, each cell in the body is an individual member of a community, although, in all organisms however the simplest, the various cells are differentiated for the performance of special functions, and to that extent have sacrificed their individuality. Each
product of glandular activity bears witness to specialised metabolic processes in the cells by which it is produced.

In recent years we have gained some insight into the mechanisms by which regulation is effected, and of the importance in this connection of the internal secretions of glands, ductless and others. We see how disease of a gland which yields such a secretion may disturb the metabolic balance in the direction of excess or defect, and in so doing may influence growth and development. Such studies are profoundly modifying our conceptions of such anomalies as obesity and infantilism, and we are learning that the glands which may be classed together as members of a hormonopoietic system constitute a group of balanced regulators of metabolism, although it may be conceded that, in this connection, theory tends for the moment to outstrip established fact. However, the internal secretions are implements, rather than originators of control. The hormones themselves but chemical products of certain specialised cells, and the activities of the glands which produce them are themselves under the control of the vegetative nervous system, which transmits to them impulses in response to the chemical demands of the tissues. Thus, in a sense, the regulation of metabolism is automatic.

**Protective Mechanisms.**

The mechanisms of defence adopted by the body are of various kinds. Some are comparatively simple chemical reactions, as when free acids are neutralised by ammonia diverted from its ordinary path to the formation of urea; or when aromatic poisons are combined up with sulphates, and are excreted in harmless forms. But aromatic poisons are also combined with products of protein or carbohydrate metabolism, with the protein fraction glycine to form the harmless hippuric acid and its allies, or with glycocenic acid to form compound glycuronates. Other mechanisms are far less simple, and the very nature of the protective agents is beyond the ken of the chemist. These are the agents known as antitoxins, agglutinins, precipitins, oposonins, and the like.

Quite recently the researches of Adherhalden have opened up a new field of such studies by revealing the production of protective ferments, capable of destroying protein substances foreign to the organism. It would seem, indeed, that each constituent cell of the body brings into play its enzyme-forming powers to meet an emergency. It is a question of unusual interest whether or not these protective mechanisms have been evolved to meet the assaults of those toxic agencies to which the organism is specially exposed, or whether an entirely new mechanism can be devised, at any moment, to meet an unforeseen emergency. Evidence may be adduced in support of either hypothesis. The laws of chemistry are so invariable that, given certain conditions, definite reactions may be expected to occur. We are able to predict the formation of compounds which may never have existed previously, and to foretell their properties with some degree of accuracy. So we might expect that a given poison launched into a medium in which a number of metabolic products are present will combine with one or other of these. But in the human organism the conditions are far less simple than in the laboratory, and we are driven to suppose that enzyme action is concerned in the production of such compounds as hippuric acid or a compound glycuronate; and we may well imagine that, even when the requisite materials are forthcoming, combination may fail for lack of the required enzyme.

**Disorders of Metabolism.**

Diseases of the alimentary tract cause impairment of the intake of nutritive materials, and changes wrought, by the bacteria which inhabit the intestines, upon the intestinal contents, may result in the formation of poisonous products which undergo absorption, to the great detriment of the organism. When the kidneys are the seats of disease, the elimination of waste products—the hygiene of the tissues—is impaired, to a greater or less extent, and these products accumulate in the organism where they induce a chain of morbid effects which culminate in the stormy symptoms of uremia.

It is because disease of glands of internal secretion produces such profound disturbance in the chemical field that we have learnt to recognise the important part which they play as regulators of metabolism. We see how functional inactivity of the thyroid gland renders sluggish the metabolic processes as a whole, whereas its over-activity—if that be the correct interpretation of the phenomena of exophthalmic goitre—causes the metabolic fires to burn too brightly. We see also how a too active pituitary gland stimulates the organism to abnormal growth, whereas less of its functional activity brings in its train obesity and recessive infantilism. Phenomena of a like order result from diseases of the adrenal and pineal glands, and we are only beginning to learn how great a part variations in the secretion of adrenalin by the chromaffin tissues may play in connection with a number of maladies in which the adrenals themselves are not primarily implicated. Indeed, it may be said that all diseases, whether they affect the organism as a whole or whether their brunt be borne by single organs, bring about greater or less disturbance of metabolism. The field of chemical pathology is practically coextensive with the field of medicine.

In the case of many maladies, even of the more acute and graver ones, the chemical disturbances which they bring in their train are far less conspicuous than the structural changes. In others, again, the metabolic disorders occupy the fore front of the clinical picture, as is the case in those maladies which we are accustomed to group together under the collective name of "diabetes."

It is natural that the attention of chemical workers in medicine has always been directed to such "diseases of metabolism," and the problems which they present are still very far from solution.

**The "Deficiency" Diseases.**

Hitherto we have been considering what may be described as positive diseases, which result from attacks upon the organism by morbid agents introduced from without, but there remains to be considered a group of maladies which may be classed as negative, seeing that they have their origin in the withholding of some portion of the supplies which the organism derives from external sources, and upon which its well-being depends. The extreme example of such a
disease is starvation—a condition in which the body, being deprived of its food supplies, lives for a time upon its own fats and carbohydrates, and ultimately upon the proteins of its tissues. Minor degrees of the condition are induced by restriction of the intake below an adequate caloric value of proteins below the amount compatible with maintenance of nitrogen balance or by complete deprivation of carbohydrate foods.

Of much interest are certain maladies which result from dietetic shortcomings of far less obvious kinds—defects which cannot be estimated in terms of calorie value or nitrogen balance. It is becoming evident that a normal dietary must contain constituents of which we have hitherto taken no reckoning, just as the air which we breathe contains gases of the existence of which we had no inkling until recent years. The new study of vitamins and of the effects of a diet consisting of pure proteins, fats, and carbohydrates upon the growth of young animals, is beginning to throw light upon the nature of such factors, exogenous hormones, if I may so style them. That scurvy results from errors of diet has long been known, but the dietetic factor in the causation of beri-beri is of far more recent recognition.

It is not surprising that such diseases of defect, when once recognised as such, are far more readily amenable to treatment than many others. The missing factor supplies the specific remedy. Starvation is readily cured by food, and scurvy by a diet of fresh meat and vegetables, just as myxoedema yields to treatment by thyroid extract; but in all such cases continuous administration of the missing factor is essential for the continuance of well-being.

The Help of Chemistry in Therapeutics.

To turn to the field of therapeutics, there is no branch of treatment in which chemistry should help us more than in dietetics, but there is none in which we rely less upon the guidance of science, and in which the influence of tradition is so powerful. In so far as tradition embodies the accumulated experience of mankind, and of generations of sufferers from particular maladies, it is entitled to our fullest respect, and is sometimes our safest guide. But too often it rests upon the dicta of some teacher of the past, which have been repeated so frequently that they have assumed an authority to which they have no real claim. I am far from maintaining that our dietetic prescriptions must always have a scientific basis, for our knowledge does not suffice to render this possible. Indeed, in many branches of treatment, there is danger in setting up too rigid a standard. A prescription which aims at the attaining of some particular object, although based upon scientific reasoning, may fail because we are, not able to take into account all the conditions of the experiment. Not a few therapeutic measures have been introduced in deference to scientific reasoning which has since been shown to be unsound, and some of these—such is the irony of things—have nevertheless proved of real value.

There are scientific grounds for the belief that mankind habitually takes too much protein food than is required for the due nutrition of the tissues, and undoubtedly the amount taken habitually exceeds that required for the maintenance of nitrogen balance. As regards details of dietary, I would venture to assert that two-thirds of the restrictions imposed upon sufferers from particular maladies and no real justification in the teachings of science or of Bible. How contradictory are the directions given by different advisers to gouty patients as to details of dietary, and how few of them can be justified by argument when called into question!

Modern diagnostic methods enable us to recognise diseases of which our fathers never dreamed, and to detect the more familiar maladies in those early stages in which they are most amenable to control. So long as they are used in conjunction with the older clinical methods, and not merely as short cuts to diagnosis, they prove unqualified boons. Nor can it be questioned that the range of efficient treatment is being extended widely. But let us not forget how much we owe to the work done by our fathers with the less efficient methods at their disposal. We begin where they left off; the harvest which we are reaping they sowed; thanks to their advances we are able to advance yet further. If they knew less than we do, they had one great advantage over us, in that they had more time for thought.

THE SURGEON OF THE FUTURE. (a)

By SIR JOHN BLAND-SUTTON, F.R.C.S.,

Surgeon to the Middlesex Hospital.

The art of surgery is probably as ancient as the art of war, and is practised by warlike savages who have never been influenced by civilisation. The antagonistic callings of the soldier and the surgeon have been markedly modified by the progress of science. It is believed by many that the ingenuity exercised in the invention of methods for destroying life will make war impossible, and the discovery of the causes of diseases and the perfection of preventive medicine will render physicians and surgeons unnecessary. The belief in each instance is futile. The art of the surgeon will be required as long as civilisation endures; but their methods have undergone great changes, and greater are impending. Gunpowder revolutionised warfare; the discovery of anaesthetics and the invention of the microscope completely changed surgical methods. The enormous impetus which the discovery of anaesthetics gave to surgery threatened to extinguish it as an art, for post-operative suppuration and pyaemia became endemic plagues in all populous cities where the surgeon plied his craft. The utility of chloroform in the diagnosis of hysterical contractions, phantom tumours and spurious palsy would require a surgical anatomy even more complete than that of the present day, but it is not yet sufficiently appreciated. The surgery of the viscera is one of the remarkable extensions that followed the introduction of anaesthetics. Abdominal organs, such as the spleen and omentum were removed when extruded through accidental rents made by knives, spears, swords, scythes, sickles, and similar forms of violence. And its lost merit is to be appreciated. The surgery of the viscera is one of the remarkable extensions that followed the introduction of anaesthetics. Abdominal organs, such as the spleen and omentum were removed when extruded through accidental rents made by knives, spears, swords, scythes, sickles, and similar forms of violence. And its lost merit is to be appreciated.

The case of division was successfully performed in Roman times, and many a child, to use Shakespeare's phrase, "was from his mother's womb untimely ripp'd." This form of delivery has been effected by obstetricians of every time and place; by a patient on herself, and by the horn.

(a) Abstract of Address in Surgery delivered at the Annual Meeting of the British Medical Association, held at Aberdeen, July, 1914.
of a mad bull; in some instances mother and child survived. The success that followed this inartistic mode of delivery is instructive: forty years ago, Caesarean section had an alarming mortality, when performed by an unskilled operator, whilst the spayer and guillotine, in Mr. Liston's hands, was attended with almost invariable success. Lister railed at the riddle. To-day wounds made and closed in the course of a surgical operation unite with a certainty that can scarcely attract attention. Surgeons rarely pause to think what would happen were surgical wounds failed to heal. In the early days of abdominal surgery the incisions often failed to unite, and such patients frequently died. I shall later on place facts before you to show that failure of intestinal wounds to unite is one cause of the high mortality following operations for cancer of the colon. One of the most healthy intestines takes place quickly and perfectly.

**Surgery and the Microscope.**

It is usually described the remarkable progress of surgery to the discovery of anaesthesia and that perfection of methods designed to prevent wound infection, but we must not forget that most important was the invention of the microscope, without its assistance the minutiae which effect such great changes in organic and inorganic nature, and on it, so many varieties of infective diseases in man and plants, would have remained not only hidden but unsuspected. This important instrument of research, perfected by earnest workers mocked at as "brass and glass men," is now indispensable in clinical routine. Every improvement in the construction of the microscope has led to an increase in knowledge of the cause of disease. It has also become a means of popular instruction and amusement. Even embryologic processes are displayed to interested pleasure seekers on cinematographic films of "palaces" and schoolchildren are instructed in physiology, including the microscopic features of the blood. Disorders of the functions of the blood-forming organs, especially red marrow, and the significance of an excessive production of leucocytes has come to be thoroughly appreciated by surgeons that under certain conditions an excessive proportion of white corpuscles in the blood is a more emphatic sign to a surgical operation than sugar in the urine. It is in this direction that the increase of pathological knowledge, especially the form of it called clinical pathology, will influence operative surgery in the future. The light microscopic studies of the cord through the lumbar puncture acts as a megaphone to the surgeon when contemplating the removal of an enlarged spleen. The extirpation of a leucemic spleen is always followed by death, and this experience is crystallised in practice, for an abdominal tumour resembling a spleen always suggests a blood count.

**The Cerebro-Spinal Fluid in Surgery.**

Fifty years ago our knowledge regarding the physiology of the brain and spinal cord was of an elementary kind. It was the custom to teach that the cerebro-spinal fluid served as a watershed for the brain in order to preserve it from harmful concussions. In my student days this teleological explanation tickled my fancy, and I suggested to the lecturer on anatomy when the ethmoid of the skull of the cat, on this wise precaution of nature, that the explanation was absurd, for the relative bulk of brain and cerebro-spinal fluid resembled an ironclad in a duck pond. Now cerebro-spinal fluid is used as a medium for inducing temporary paralysing analgesia—a matter of no concern to the surgeon when he is called upon to operate in conditions where a general anaesthetic would be attended with unusual risks. The diagnostic importance of cerebro-spinal fluid obtained by lumbar puncture is not only great but its utility is increasing. Examination of samples of the cerebro-spinal fluid obtained by tapping the spinal theca is a routine in diagnosis.

In discussing influenzal meningitis, Flexner tells us that the fluid secreted by the choroid plexuses in infected monkeys contains an antiserum which escapes by the meningeal veins, and it may become possible to make use of this fluid to instill the blood by means of compounds injected into the cerebro-spinal fluid. Here is a method of specific therapy unsuspected in our wildest dreams: Science transforming the cerebro-spinal fluid into a pool of Bethesda! Enterprise surgeons are now devising methods by which this makes possible the intrathecal injection of salvarsan, in common with all arsenical compounds, irritate the spinal cord. To overcome this difficulty, salvarsanised serum obtained from the patient is injected into his cerebro-spinal fluid and tolerated. This is a good example of practical ingenuity. The results of surgical enterprise on cerebral tumours are unsatisfactory; the mortality is great and the cure of the patient of the disease is rare. The indefiniteness of gliomata formations makes them extremely unfavourable for operation, to say nothing of the difficulty in localising cerebral tumours in non-motor areas. It is probable that compounds will be discovered that can be injected into the cerebro-spinal fluid and cause gliomata to shrivel in an incomprehensible manner. Gliomas disappear under potassium iodide, mercury, or salvarsan, and thus abolish some of the most uncompromising operations of modern surgery.

**The Surgery of Malignant Growths.**

Investigations of the minute structure of morbid growths have been mainly useful in separating the so-called benign tumours from those which inevitably destroy life. Thirty years ago the two groups were regarded as distinct. It is true that types can be distinguished as innocent or malignant, but each genus of the so-called innocent group, with the exception of lipomas, contains species in which the histological features of malignancy shade away into those indicating malignancy. It is a matter of great importance when a declaration of malignancy entails the sacrifice of an organ or a limb. The horror patients entertain of malignant disease, and the stigma they think it imprints on the family reputation leads to willing submission when the surgeon offers operative treatment. It is an impression deeply ingrained in the profession that the presence of malignant disease justifies an operation, however extensive or dangerous, for its relief. Let us satisfy ourselves that surgical gambling with malignant disease is justified. There are two organs in the body often the seat of cancer and often attacked by surgeons—the uterus and colon, in connection with which this question may be fairly considered.

The results of removal of the uterus for cancer in its neck are by no means uniform even when the conditions are apparently favourable. The microscopic features of cancerous growths do not help in explaining variations in the clinical course of the disease. There are intrinsic and extrinsic factors concerned in estimating the malignancy of uterine cancer which have only recently been appreciated. Our predecessors in the art of surgery failed to recognise a remarkable alteration in the appearance of advanced malignant patients the subjects of advanced malignant
disease, which they expressed by the phrase cancerous cancer. This expression has a special relation to cancer, it is due to the entrance into the circulating blood of toxic substances secreted by the bacteria and cocci which colonise cancerous growths in exposed situations. The relation of bacteria to cancer is a matter of first-rate importance to the surgeon, and influences his work very materially. Inoperable cancers of the breast are sterile. Cancer of the tongue usually swarms with streptococci, and the neck of a uterus when cancerous is colonised by staphylococci, or streptococci, and the coli group. This led me to make bacteriological investigations and treatment postulating the removal of this large-intestinal flora. The results are not gratifying. Resections of the caecum, or portions of the colon, are attended with a high rate of mortality, and of those who survive operation early recurrence or dissemination is the rule. Surgeons know this, and in order to improve the results of operative treatment postulating investigation have been made on the distribution of the blood and lymph vessels of the colon. In spite of much admirable work and surgical enterprise, cancer of the large intestine is as obnoxious to the surgeon as hysterectomy for cancer of the neck of the uterus to the gynaecologist, and for the same reason—sepsis.

The radical method of dealing with cancer of the colon consists in free resection of the cancerous portion in favourable cases; this requires a complicated operation for the reanimation of the bowel, entailing a suture which must be not only watertight but gastight. One of the first requisites for the method of the neck of cancerous uterine to enter into consideration. Colle cancer sometimes leads to abscess when it is infected by the coli group. The frequency with which visceral cancer mimics inflammatory conditions and misleads physicians and surgeons alike is due to sepsis. The appreciation of the causes of failure in the surgical treatment of colorectal cancer should exercise some influence for good. It is by no means uncommon to see surgeons clad in sterilised overalls, gloves, caps, masks, and top boots resecting a cancerous segment of colon swarming with pyogenic microorganisms. This can only be described as surgical heresy. Some of our methods of finding bacteria in the course of an operation are almost as clumsy as attempts to kill fleas with bludgeons.

THE SURGEON OF THE FUTURE.

In pre-Listerian days the path to surgery lay through the dissecting-room. A thorough practical knowledge of the anatomy of man was and is indispensable to a sound surgeon. Many surgeons whose names are prominent in the history of surgery—from John Hunter to Ferguson—took it as a matter of course that all surgeons should have had an anatomy by dissection. Surgeons no longer act as anatomists nor conduct post-mortem examinations; the principles of antiseptic surgery forbid such occupations. The practical training in the dissecting-room and post-mortem room teaches men something of the condition of the body, but this is only the preparation of the student for the two books—the appreciation of tissue; this means, in plain terms, the power to recognise organs and tissues, normal and abnormal, at sight or by touch in the course of an operation. Surgeons are of two types, they are either craftsmen or biologists, and we can call them by these names because the variations in technique—metal plates, wires and screws for bones; or fancy methods of suturing wounds. Some expend their ingenuity on surgical cutlery and improve the knives and needles. The utility of a simple tool such as the clip forces is inestimable. In spite of much ingenuity among surgeons, an ideal ligature material awaits discovery. Clever contrivances like the laryngoscope, bronchoscope and cystoscope have revolutionised special branches of surgery. Another useful instrument, the osteoscope, requires for its successful use a surgeon with the instincts of the sword-swaller and the eye for a neck. This was the kind of my colleague, Alfred Johnson. I witnessed through the cystoscope a stone slowly extruded from the vesical orifice of the ureter.

The biological surgeon studies pathology in its broadest aspect, and investigates, in the laboratory, the problems of morbid anatomy and bacteriology. The diagnostic value of reports issued from the laboratory by the biologist and the bacteriologist, to be of value, must be estimated with the help of clinical experience. If the surgeon has had no experience in bacteriological methods he must accept the reports from the laboratory with the hopefulness of a patient swallowing physic compounded from a prescription he does not understand and which he is often unable to read.

The skill, ability and dexterity with which surgeons remove a kidney, the uterus, or perform extensive resection of the intestine, great and small, can be witnessed almost daily in the splendid hospitals of large cities, but surgical effort is handicapped by streptococci and the coli group, which are very resistant to chemotherapy. There is something more soothing in submitting septic morbid growths to what Ehrlich picturesquely terms a "bacteriological siege." The magical effects of salvarsan on the lesions of syphilis, acute and chronic, lead us to hope that this compound will assist in the elimination of cancer of the mouth and tongue, for in these situations cancer is often engrafted on chronic syphilitic lesions. It is reasonable to believe that within a few years surgeons will notice a marked decrease in the number of men with cancer of the lips, gum, tongue, and pharinx, and of women with cancer of the vulva. The extinction of these forms of cancer will relieve surgeons of some of the most distressing and unsatisfactory operations they are called upon to perform.

In regard to the cure of malignant disease, there is most hope in chemotherapy. In detecting the cause of cancer histology has proved a false dawn, but, like that peculiar light which precedes the dawn in the tropics, it is fascinating. We can tell how low the stars shall have to sink for the real dawn! We need not despair; the zeal, enthusiasm and acumen of laboratory workers fill us with the hope that the ideal of all practitioners of medicine and surgery is attainable—the control of all forms of infective disease.
SPECIAL REPORTS.

ROYAL FREE HOSPITAL.

VENTRAL HERNIA.—Mr. Willmott Evans operated on a gentleman who had a ventral hernia. The history was that three years ago she suffered from appendicitis, for which she had an operation at another hospital. An abscess had been present, for which drainage was employed. When the wound had healed a recurrence of this condition she had had two operations, but neither had resulted in a cure. On admission at a point about an inch and a half external to the outer margin of the right kidney, a small firm body about three inches long and a half where palpation showed that the greater part of the abdominal wall was absent. When the patient coughed a prominence appeared at this part. The patient having been anaesthetised, an incision was made about three inches long along the outer border of the hernia; the peritoneal cavity was opened and it was then found that the sac was adherent to the skin over the greater part of the hernia. With great care the bowel was separated from the attached skin; it was then returned into the abdomen and the scar of the skin was excised. The peritoneum was then united by a continuous silk stitch and then the insular planes were united in turn, in each case some omentum placed. External drainage was employed, to overlap that portion of the external oblique and its fascia which was in the wound. The skin was united with silk and the wound was dressed.

Mr. Willmott Evans says, although ventral hernia might result from a blow not damaging the skin, but weakening the abdominal wall by the rupture of some muscular fibres, yet in the majority of cases it was the result of a wound of the abdominal wall, either intentional as in an operation, or accidental. The great increase during the last twenty years in operations for appendicitis has unfortunately resulted in an increase in the number of ventral hernias. The operation for appendicitis is especially likely to lead to weakness of the abdominal wall if long lasting drainage has been employed; but even when drainage has been used a ventral hernia would appear in only a small proportion of the cases. A ventral hernia is almost unknown in cases in which the Battle incision has been used for the rectus muscle offers great resistance to the stretching of the scar. It is not at all uncommon to find some structure adherent to the hernia. This may be omentum or intestine, and the operation on such a structure requires to be done with great care; sometimes it is advisable to cover the bare patch in the wall of the bowel with a piece of omentum in order to prevent further adhesions forming. Overlapping the inadmissibility of different layers of fascia, and at the site of the hernia is of great value in preventing recurrence, and it is sometimes necessary to employ a filigree or a fascial transplant in cases where the abdominal wall is naturally weak or atrophic. The after treatment is not without importance: it is essential that no undue strain should be thrown on the abdominal wall until the tissues have become consolidated; therefore, when the bandages are discarded they must be replaced by an abdominal belt which should be worn for at least six months, or better, for a year after the operation. He thought it was hardly necessary to state that there was an essential difference between ventral hernia and umbilical hernia, as regards the treatment, but the same principle obtained that the layers of the anterior abdominal wall must overlap.

As to the subsequent history, the wound healed by first intention as the patient was able to leave the hospital after the operation wearing an abdominal belt, and when heard of some months later, no recurrence had taken place.

Six medical men, comprising the voluntary staff at the Barry Accident Hospital, have decided to tender their resignations to the District Council, and have given this week notice. The most serious consequence of this action was the engagement of a surgeon at £500 a year.

OPERATING THEATRES.

THE EIGHTY-SECOND ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT ABERDEEN, 1914.

(By Our Special Representative.)

SECOND ARTICLE.

GREETED with such a "Bon-accord" welcome as only Aberdeen could give, the eighty-second annual meeting of the Association have every reason to recollect their visit to the "Granite City" with pleasureableness feelings. The weather, if not brilliant, was kind, and the cool northerly breezes provided an invigorating tonic which made the meeting more suitable to those coming from the south. All the arrangements for the entertainment of visitors, and especially of the ladies, were excellently carried out, and much praise is due to the energy and forethought of Dr. T. Fraser, the Hon. Local Secretary, and to the various local committees for combining to render the 1914 meeting one of exceptional interest.

At the annual general meeting on the Tuesday afternoon, Sir Thomas Clifford Allbutt, K.C.B., M.A., F.R.S., Regius Professor of Medicine in the University of Cambridge, was introduced, and it was announced that the meeting in 1915 would be held in Cambridge. It has been decided to continue the Scottish office for the Association with a whole-time medical secretary, and upon a vote being taken at the representative meeting, Edinburgh was selected as the centre for this office.

RELIGIOUS SERVICES.

This year there were no less than three services arranged for the Association, of which the principal one of which, however, was that held at the West Parish Church of St. Nicholas (Church of Scotland), Aberdeen, at 9 a.m. on the Wednesday morning. Those attending this service were the Moderator of the General Assembly, the Right Reverend Dr. Baillie, and the Rt. Rev. Dr. John Gordon and Thomas Fraser. Selecting for his text St. Luke xxii., 27, "I am among you as He that serveth," the Rt. Rev. Dr. Anthony Mitchell, Bishop of Aberdeen and Orkney, from Rev. xxii., 2, "And the leaves of the tree were for the healing of the nations," he referred to the healing influences which proceeded impalpably from the highest self of the physician whose work called forth the finest qualities of the human soul, especially those of compassion, mercy, courage, and self-sacrifice.

The service for Roman Catholic members was held in St. Mary's Cathedral. After Mass was celebrated, the Rt. Rev. Dr. Menny, the Administrator of the Cathedral, preached the sermon from Ecclesiastes viii., 3, "The wise man of the generation to come give knowledge to men that He may be honoured in His wonders." He said that Aberdeen was proud to acknowledge the debt the Church owed to the illustrious Bishop Finlaystone, who established in their city the first chair of medicine in this country.

The President's Address.

The Music Hall in Union Street was crowded on Tuesday evening to hear the President's address. The proceedings were opened by Lord Provost Maitland, who welcomed the Association officially to Aberdeen.
After the foreign and colonial delegates had been received, gold medals of merit were presented to Mr. T. Jenner Verral, Chairman of the Representative Meeting, and to Dr. Edwin Rayner, Treasurer of the Association. Sir John Bland-Sutton delivered his presidential address on "The History of the Medical School of Aberdeen," full of interesting historical allusions, an abstract of which will be given in our columns next week.

THE ADDRESS IN MEDICINE.

The Mitchell Hall, Marischal College, was well filled on Thursday morning to hear the address in Medicine delivered by Dr. Archibald E. Garrod, M.D., F.R.C.P., F.R.S., Physician to St. Bartholomew's Hospital, who chose for his subject some phases in the history of medical science and art. He traced the growth of pathology, bacteriology and chemistry in its medical aspects and stated their practical bearing upon modern medical therapy. The address appears elsewhere in our columns (p. 147).

THE ADDRESS IN SURGERY.

This was delivered in the Marischal College on Friday at Midday by Sir John Bland-Sutton, F.R.C.S., Surgeon to the Middlesex Hospital, who, in dealing with "The Surgeon of the Future," spoke of "surgical gambling with malignant disease," and pointed to the salient impression that the presence of a cancerous growth in a patient requires an operation. He thought that the relationship between sepsis and cancer was an important matter for the surgeon. In regard to the cure of cancer he declared that the greatest hope lay in chemotherapy. Sir John Bland-Sutton made his audience laugh when he said that the surgeon who used the osophagoscope required for its successful use the instincts of the sword swallowers and the eye of a hawk. A full abstract of this most suggestive address appears on p. 149.

THE ANNUAL DINNER.

On the Thursday night, as is customary, the annual dinner of the Association was held at the Music Hall, Union Street. The company, which embraced 400 ladies and gentlemen, included the following guests of the President and members of the Association—Lord Provost Maitland; the Principal of the University, Rev. G. A. Smith, D.D., LL.D.; the Right Rev. Professor Nicol, Moderator of the Church of Scotland; the Right Rev. Dr. Chisholm, Bishop of Aberdeen; the Right Rev. Anthony Mitchell, Bishop of Aberdeen and Orkney; Rev. G. H. Donald, West Parish Church; Mr. J. E. Cramb, Lord Provost; Mr. John Fleming, Lord Provost; Mr. Irving, of Drum; Mr. Harvey Hall, President of the Society of Advocates; Rev. Ronald Douglas Duncan, Secretary of the Society of Advocates; Dr. John Strachan, Provost of Aberdeen Royal Infirmary; Mr. Ledingham, Chairman of the Royal Asylum Board; Mr. John Michie, H.M. Commissioner, Balmoral; Dr. J. A. Macdonald, Chairman of Council, B.M.A.; Mr. Edwin Rayner, Treasurer, B.M.A.; Mr. T. Jenner Verral, Chairman of Representative Meetings, B.M.A.; Dr. A. Cox, Medical Secretary, B.M.A.; and Mr. Guy Elliston, Financial Secretary, B.M.A.

After the loyal toasts had been duly honoured, Mr. T. J. Verral proposed "The City and University of Aberdeen." Speaking of the advantages of its university degrees, he said that those who knew best the Aberdeen born and bred must conclude that into his composition there have entered a considerable proportion of the far-damed local building material—polished granite. (Applause and laughter.)

Lord Provost Maitland and Professor G. Adam Smith, B.M.A., respectively presented to the City and University respectively, the toast of "The British Medical Association," which was delivered by Dr. Alexander Scott, of Glasgow, who dealt with the industrial aspect of alcoholism, and Mr. McAdam Eccles, who emphasized the need for special research into the question of the use of alcohol in the circulatory blood. Dr. Crichton Miller, and Mr. T. H. Bickerton (Liverpool), also spoke.

THE UNIVERSITY OF ABERDEEN.

The University authorities gave a reception on the Wednesday night in the Mitchell Hall of the magnificent Marischal College, which was attended by 3,200 members and their lady friends. A capital organ recital was contributed by Mr. J. M. Nisbet, and further music was provided by an excellent orchestra. Academic costume was worn by the majority of the guests.

On the Friday morning, the Senate of the University conferred the degree of LL.D. (honoris causa) upon Sir John Bland-Sutton, Dr. A. E. Garrod, of St. Bartholomew's Hospital, London, and Sir Victor Horsley (in absentia). Mr. T. Jenner Verral, Chairman of the Representative Meetings, and Mr. W. T. Hayward, of Australia. (To be continued.)
CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

At the Hufeland Society, Hr. Strauss showed a number of preparations, amongst them a case of Ulcerous Proctosigmoiditis, a diverticulum of the sigmoid, carcinoma of the sigmoid flexure, affected with benign polypi at the same time, and a series of high-seated polypi which had led to the removal of the part of the gut by Hr. Ewald emphasised the importance of examining every rectal case with the rectoscope. If this were always done many errors of diagnosis would be avoided. It was important in using this that the rectum should be thoroughly cleansed beforehand. With this in view he always gave a purgative the night before and a rectal infusion from half an hour to an hour before the examination. He held this thorough cleansing to be quite necessary. In Hirschsprung's disease it was quite characteristic how easily the tube was introduced and the case with which the instrument could be moved about in the rectum. Hr. Hans Köhn remarked that multiple diverticula in the rectum were only to be met with in elderly people. Hr. Ewald claimed that diverticula were met with in the young, but they were long ones, whilst those met with in the aged were small from distasises in the muscular layers, which allowed the bowel to push through. Hr. Strauss observed that in proctogenous constipation he had recognised a distinct form of disease with distinct symptoms and etiology and requiring special treatment. This differed from that described by Hertz in one point in that Hertz, had attributed to it special features, as shown by the Röntgen rays. As the latter were not at all necessary, however, for diagnostic purposes, it was only a case of giving a neozazis of the sigmoid flexure, the case described by himself. It was not true that such conditions as he had described had been mentioned in literature, amongst others by Ewald, but before the appearance of the speaker's publications, a systematic analysis had been wanting. As preparation of the patient preliminary to the use of the endoscope he was of opinion that an enema given the night before was more suitable than an aperient, as by that the lower bowel was cleansed and further obscured by the enema above rendered evident that whenever he was about to use the endoscope and he suspected a possible wandering down of faecal matter he accompanied the washing out of the bowel by a dose of opium.

Recently there had been a case of stenosis of the sigmoid probably on a syphilitic foundation. The patient was a man, aged 60, who had suffered from lassitude for two years, who came in for operation in an acute stage, with a provisional diagnosis "carcinomatosus closure of the large intestine." The man died of peritonitis. The autopsy showed a long patch of thickening of the sigmoid commencing 3 cm. above the anus. Here was a long ulcer sharply defined with a smooth Black-Fredericks surface, undermined edges and reaching down to the muscular layer. There was also disease of the aorta in the commencing stage, an atrophic noma ulcer also in the abdominal aorta. Microscopic examination showed distinct thickening of the adventitia with lymphocytes and giant cells, also a median rent with round-celled infiltration. The whole had the appearance of syphilitic aortic sclerosis.

At the OtoLOGische Gesellschaft, Hr. Bruhl gave some account of the case of thinning of the ear.

EDUCATION OF DEAF AND HOULY.

At a meeting of the Committee of the Society of the deaf and dumb, a case of deafness was brought forward. It was a case among 3,304 children brought for examination, 258 were found suitable for the "hard of hearing" school.

General measures for management of children suffering from deafness, either total or partial, were first in the kindergarten, into which children were admitted at four years of age; the objects here were retention of power of speech when not altogether lost, for children with some remains of hearing power, efforts were made to increase and sharpen it, for the totally deaf the aim was to develop the natural voice, the deaf and dumb schools in which classes were formed according to the mental development. Continuation schools for the deaf and dumb in which trades and useful manual occupations were taught, the latter being fitted for domestic employments.

For the hard of hearing there were at present three institutions for these situated in the northern, central and southern parts. Although the hard of hearing schools were six schools, four schools was in process of erection in the north-west part of the city. It is proposed to build a continuation school for the hard of hearing also. For the hard of hearing in the municipal and private hospitals there were special classes held for them. The director of the deaf and dumb school gives special lectures to parents and relatives of the deaf and dumb as to home education of the deaf, and had a special consultation for advice in special cases.

AUSTRIA.

Vienna, Aug. 1st, 1914.

PATHOGENESIS OF QUINCKE's EDema.

At the recent meeting of the Gesellschaft für innere Medizin und Kinderheilkunde in Wien, Dr. P. Neudorff brought forward a communication which dealt with the problem of the "Pathogenesis of Quincke's Edema." The characteristic features of this clinical condition are: (1) Enlargement of the spleen, which is recognisable both by palpation and percussion; (2) intense urlobilinuria, with eventual appearance of blood urinuria; and (3) a general enlargement of the lymphatic system through the spleen, which is not so constant as that of the former; (4) peculiar properties displayed by the blood, such as increase of the hemoglobin constituent and ascent of the coloration index, immediately before the attack and during the period of the enlargement of the spleen; (5) the edema is caused by the sequestration of the blood-corpuscles from the circulation through the spleens and fat glands of the body. The second of the above-mentioned cardinal symptoms, that of urlobilinuria, is in close accordance with the pathological examination that we are dealing here with a condition of which the essential factor is a hemolytic process. Thus the presence of urlobilinuria could be readily accounted for by a relative functional insufficiency of the secretory organs of the liver, in particular of the biliary ducts, as the nerve material for the physiological formation of bilirubin, which is itself a direct result of an increased destruction of the blood corpuscles. The third characteristic of the condition in question could also be explained by a hemolytic process. An interesting and important result was procured by the data afforded by a daily systematic determination of the resistance of the erythrocytes. In the absence of the attack the minimal resistance was remarkably low, about 0.54.
during the attack it was found to be 0.4; and even increased further; the maximum resistance which had previously been considered the highest, was observed to fall to 0.34 after the onset of the attack. From these observations Dr. Nenda came to the conclusion that immediately on the development of the paroxysm the erythrocytes of very high resisting power rapidly underwent destruction, and it is probable, of course, a result of increased activity of the process of hemolysis. The ascent of the standard of minimal resistance is shown by the results of experimental research, and has also been confirmed by the experience which distinguishes us with many published data obtained in this way. Thus we have the fact of the increased resistance which follows the injection of blood deprived of colouring matter—and all these results point to the following explanation of the phenomena. As, with its resulting consequence of the development of hemoglobinuria, may be held to supply the true explanation of the increased resistance. The hemoglobin content of the serum during the paroxysm had been determined by Dr. Nenda in two instances. He would explain the characteristic external physical feature of Quincke's affection, that of acute circumscribed swelling, by a form of hydramma, which originated as a result of which we had the attack, and was clinically demonstrable from the condition of the urine and alvine evacuations, dryness of the mouth and feeling of thirst. He also pointed out the fact that an analysis of which produced a change of osmotic pressure in the interior of the vessels, has also a corresponding simultaneous effect in the surrounding tissues. Then as the resistance is not equal in the two cases, the resistance thus elevated is a matter of the area of resistance resistentia, through which the general transudative diathesis comes to find its opportunity for expression. Exogenous factors that produce a diminution of the powers of resistance of the various surrounding tissues, such as a sudden stroke or continuous heavy pressure, undoubtedly play also an important part under such conditions. Dr. Nenda had also noticed the occurrence of a retention of chlorides in the interstitial fluid which immediately preceded the attack. Thus the condition of acute circumscribed edema appeared to him as a symptom, while the disease proper—of which its presence furnished an indication—was a hemolytic process resulting from the presence of a poison.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

VENEREAL DISEASE AND NOTIFICATION.

The Medical Officer of Health for Glasgow, Dr. Chalmers, has been giving supplementary evidence before the Royal Commission on Venereal Disease. He said that he was of opinion that no form of compulsory notification, whether for any group of persons or of cases, would effect its object. His view was that the public required not compulsion, but enlightenment. He had made no authoritative statement showing the danger to life in after years of syphilis contracted at an earlier period, and of the disastrous effect on children, would help to form an enlightened public opinion which would at least induce those who might contract the disease to seek effective treatment, even if it failed in the ultimate purpose of inducing them to avoid exposure to it. The main problem at the present time was the organisation of efficient diagnostic and treatment. 

CALEDONIAN MEDICAL SOCIETY.

This Society has been holding its annual meeting and dinner in Glasgow. Dr. I. T. Macachlan, the President, occupied the chair at both. At the dinner Sir David C. McVicar, in proposing the toast of the Society, said that he had found in their records a great deal of evidence of high culture in the medicine of the Highlands. He thought they were right in having a society which upheld Celtic medicine and the credit of the Celtic past of the population of Scotland. On the subject of Celtic medicine the Society had a large number of papers, which by themselves would have filled a large number of volumes. The Chairman, in responding, said that the Society was formed in 1878 by a small but enthusiastic band of medical students in Edinburgh. At the present moment the membership was nearly 700, scattered over Scotland, Ireland, and the Dominions across the sea. The Society was chiefly concerned with ancient Celtic literature regarding medicine and cognate subjects. Dr. Barlow, the President of the Royal Faculty of Physicians and Surgeons, gave the toast of "The Universities," to which Sir Hector Cameron responded.

MEDICAL BENEFIT IN PÄISLEY.

The insured population in Paisley is something over 34,000. On the panel there are 90 doctors and 76 chemists. The number on the doctors' lists varies from 5 to 3,213. Six have less than 500 patients each; seven have between 500 and 1,000; eight between 1,000 and 1,500; four between 1,500 and 2,000; three between 2,000 and 2,500; and one has 3,213. This would seem to show that one doctor has none. In regard to sanatorium benefit the current expenditure is, it is stated, at a higher rate than the previous year. A certain portion of the medical profession may be inclined in administering this benefit if the Committee is not to fall behind. For the year to 1st ult., there were 66 applications for sanatorium benefit, of which 64 were granted and 2 were, on medical grounds, refused.

THE PARASITIC CAUSATION OF DISEASE.

Dr. J. T. Macachlan, in his recent Presidential Address to the Caledonian Medical Society, dealt with the subject of the parasitic causation of disease. He stated that the parasitic pathogens of any given disease were discovered and their habits ascertained, they could be destroyed with as much certainty as the wild beasts of the forest. It was only a question of money and the appointment of expert men to devote their entire attention to such investigation. Dr. Macachlan advised men over 60 years of age who are possessed of sufficient funds to subscribe £50,000 as their best insurance policy, to the investigation of the parasite or parasites concerned in the causation of pneumonia, which was so fatal to elderly people. In his opinion, cancer would sooner or later disclose a parasitic origin. He appealed to the large cities to appoint at least one expert to devote his entire time to the elucidation of the cause of any single infectious disease, and he predicted the final annihilation of all infectious diseases that afflict humanity.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

IMPERIAL ASPECTS OF THE POPULATION QUESTION: THE DECAY OF FRANCE.

To the Editor of The Medical Press and Circular.

Sir,—My last letter ended with a brief reference to a lengthy dispatch from the correspondent dated the 8th, headed "Coloured Labour in France." The correspondent does not even distinctly allude to the obvious sound remedies that lie at hand; he merely records the facts that already several English and African firms are at work in the coalfields of the North and the vineyards of the South; and that, handicapped by a low birth-rate and high mortality, the population of France no longer suffices to meet the demands the country has made upon it by the increase of industrial development. He does not state that all the northern neighbours of France show an enormously greater birth-rate and a much lower death-rate. He does not point out that in France the workers are due, in large part, to the deliberate action virtually of the whole of the married couples; the other to the almost complete disregard of the scientific teachings which the whole of Western Europe, except France, is acting upon. Sanitation there is more than France remains at this present day in great part medieval in character. The correspondent then goes...
to show that the magnitude of the need for labour is well exemplified in the development of the newly opened Black Country of France on the German frontier.

The correspondent dwells upon the fact that the countryside population has been quite insufficient to take up the new industry. In the new German frontier villages, have become Italian. Throughout the coal districts, among the Belgian frontier, a similar state of affairs exists. Belgians, however, have taken the place of Italians, and in this way the following national element has been absorbed:—people, whom the correspondent considers can be called "medical treatment" it must fulfill two conditions—viz, (1) It must be intended to benefit the patient; (2) It must be done with the consent of the patient. Your readers will agree that in dealing with such a delicate matter as these regulations, to be satisfied in ordinary medical practice. The Committee does not consider that the mere infliction of pain is "torture," but holds that what constitutes "torture" is an object in view when the pain is inflicted. To take a simple example: no one would maintain that when a dentist pulls a tooth a he is inflicting "torture," though he may be causing severe pain. Everyone will, however, agree that if a Jew's tooth is pulled out in a country where those who his money is hidden, torture has been inflicted. The Committee maintains that forcible feeding is carried out to compel the prisoner to serve a sentence of imprisonment, and is continued until it is evident to the Home Office that it is safe to discharge the prisoner. Is your own argument, putting the present regulations, can be settled by the introduction on the large scale of North African natives, preferably Kabyles, who, in small numbers, have given great satisfaction.

In a previous letter I mentioned the scheme lately broached for augmentation of the French home army by drafts of Africans from their colonies, and pointed out that such a proposal resembles really like the proposal for an European winter campaign. In the event of a European war the French would need to reinforce all their African garrisons by troops from home, and this—was clearly seen when they were sent to the colonial enterprise. It would be difficult to imagine a conflict with Germany, and might alone render their position from the first hopeless. All these facts—the danger to the State primarily arising from the restriction of the birth-rate—have, as I showed in an earlier letter, been constantly urged upon their people by leading French statesmen. The effects upon the individual citizens, and upon the children when the family never on the average exceeds two, and the effects upon the race of a system of artificial selection of the wrong kind, have all been continually examined and thirsted before the eyes of Frenchmen by their men of letters and men of science. The teachings and exhortations have been made in vain, and the French peasant has refused to recognise anything himself in the nations of old that were led to decay and ruin by like causes. To some of these latter topics I may, with your permission, perhaps return.

I am, Sir, yours truly,
Henry Sewill,
Earlswood.
July 25th, 1914.

P.S.—It was by accident evidently that this letter did not appear along with that of "Neo-Malthusian" in your last issue, July 20th. I have previously dealt with some of the fallacies he enumerates, and shall hope to deal with the rest, if you will allow me, later on.—H. S.

July 30th.

FORCIBLE FEEDING.

To the Editor of The Medical Press and Circular.

Sir,—The leading article on "Forcible Feeding Protocols in your issue of July 22nd has been discussed by the Forcible Feeding (Committee on Personal). You say the question is begged by the use of the word "torture." The Committee is prepared to justify its use of that word. The term that is used by those in favour of forcible feeding is "Medical treatment." Consequently, if considered that the term "medical treatment" may not express all the conditions—viz, (1) It must be intended to benefit the patient; (2) It must be done with the consent of the patient. Your readers will agree that in dealing with such a delicate matter as these regulations, to be satisfied in ordinary medical practice. The Committee does not consider that the mere infliction of pain is "torture," but holds that what constitutes "torture" is an object in view when the pain is inflicted. To take a simple example: no one would maintain that when a dentist pulls a tooth a he is inflicting "torture," though he may be causing severe pain. Everyone will, however, agree that if a Jew's tooth is pulled out in a country where those who his money is hidden, torture has been inflicted. The Committee maintains that forcible feeding is carried out to compel the prisoner to serve a sentence of imprisonment, and is continued until it is evident to the Home Office that it is safe to discharge the prisoner. Is your own argument, putting the present regulations, can be settled by the introduction on the large scale of North African natives, preferably Kabyles, who, in small numbers, have given great satisfaction.

In a previous letter I mentioned the scheme lately broached for augmentation of the French home army by drafts of Africans from their colonies, and pointed out that such a proposal resembles really like the proposal for an European winter campaign. In the event of a European war the French would need to reinforce all their African garrisons by troops from home, and this—was clearly seen when they were sent to the colonial enterprise. It would be difficult to imagine a conflict with Germany, and might alone render their position from the first hopeless. All these facts—the danger to the State primarily arising from the restriction of the birth-rate—have, as I showed in an earlier letter, been constantly urged upon their people by leading French statesmen. The effects upon the individual citizens, and upon the children when the family never on the average exceeds two, and the effects upon the race of a system of artificial selection of the wrong kind, have all been continually examined and thirsted before the eyes of Frenchmen by their men of letters and men of science. The teachings and exhortations have been made in vain, and the French peasant has refused to recognise anything himself in the nations of old that were led to decay and ruin by like causes. To some of these latter topics I may, with your permission, perhaps return.

I am, Sir, yours truly,
Henry Sewill,
Earlswood.

July 30th.
OBITUARY.

JAMES DUNCAN FARQUHARSON, M.D., OF NEWCASTLE.

We regret to announce the death of Dr. James Duncan Farquharson, of Westgate Hill, Newcastle, on the 27th July. Deceased was one of the best known medical practitioners in the city, and had an extensive practice in the West End. He had been in failing health for some time. The news of his death came as a surprise to a wide circle of friends, by whom he was held in the highest esteem.

Dr. Farquharson was born at Perth on August 14th, 1858, the younger son of the late David Farquharson, a contractor in that borough. He studied medicine at Glasgow University, and in 1884 took the degrees of M.B. and C.M., and obtained first-class honours. At Glasgow University he was for two years his University boat. In later life he was particularly interested in hunting and fishing, but he always retained his interest in all forms of athletics. He was Surgeon-Major to the 1st Newcastle-on-Tyne Royal Garrison Artillery Volunteers. He was a keen student of local municipal affairs, and was at one time a member of the Newcastle Council, to which he was elected as the representative of the Arthur’s Hill Ward in 1897.

Dr. Farquharson was a Fellow of the British Gynaecological Society, and also a Fellow of the Edinburgh Obstetrical Society. He occupied the position of Secretary for some time to the Northumberland and Durham Medical Society, and was President of the Newcastle Scottish Association. Dr. Farquharson was married in 1902 to Miss Adeline Falder, the eldest daughter of Mr. Edward Crossley, of Barnborough Grange, Doncaster.

MEDICAL NEWS IN BRIEF.

Death from Acute Haemorrhagic Pancreatitis.

At a recent Sunderland inquest on the body of Haswell Thompson, aged seven, the medical evidence showed death was due to an uncommon disease. The father of deceased said the boy had always seemed healthy, and even on the morning of the day when death took place made no complaint. Deceased, he said, against his wishes used to go to the Scottia Engine Works and ask the men there for bread. Why he went witness could not say, for he got plenty of good food at home.

Dr. Anderson stated that when he saw the boy, about half an hour before death, he was in a state of collapse. The heart was, however, beating strongly, and witness was then unable to say what was the matter. The post-mortem which he and a colleague held later revealed that death was due to acute haemorrhagic pancreatitis. This was a rare disease, said the doctor, and the cause of it was not exactly known. In answer to the Coroner witness hazarded the opinion that there might have been set up by the eating of bad fruit or other unfit food.

A verdict of death from acute haemorrhagic pancreatitis was returned.

Successful Claim of Factory Worker for £25 Damages.

In the City of London Court last week, before Judge Atherley-Jones, K.C., and a jury, Daisy McShee, factory hand, 23, Clapham Junction, made a claim, through her father, under the Employers’ Liability Act against the Royal Petroleum Company, Ltd., St. Helen’s Court, to recover £25 as damages for personal injuries suffered while working for them.

The plaintiff alleged that on April 28th she entered the service of the defendants. It was her duty to assist in soldering with an acid or chloroform mixtures of motor-spirit, and her hands were poisoned by the acid which was used. She complained to the defendants’ foreman, who told her to get on with her work and not to think of it.

The defendants’ case was that the liquid which the plaintiff used was what was technically known as “killed,” was innocuous, and that Mr. Doughty, the defendants’ counsel, put some on his hands and lips, and found there was no danger in doing so.

The jury found a verdict for the plaintiff, and awarded £25 damages.

Death under Anæsthetic.

Mr. Clitterhouse Smith, Deputy Coroner, held an inquest at Brixton last week respecting the death of Mrs. Emily Mates, aged 59, a widow, of 12, St. Nicholas Road, Balham.

Dr. G. Grimmer, of Balham, said that, owing to deceased’s condition, the operation was absolutely necessary. A week previously she had been thoroughly examined, and found to be in a fit state to undergo the operation, which was not considered a serious one. Shortly before the operation deceased was again examined. Witness had no idea that the deceased would be able to administer the anæsthetic, and for a trained nurse to be present. Witness had only concluded the operation, which took from 30 to 35 minutes, when Dr. Nunn told him that deceased was unconscious, and that chloroform well. Just as the operation was finished, he noticed a change in deceased, and acquainted Dr. Grimmer at once.

Dr. J. D. Stubbs, of Tulse Hill, who had made a post-mortem examination, said that death was due to syncope, following the operation, while under the anæsthetic. Chloroform was the proper anæsthetic to use.

The jury returned a verdict in accordance with the medical evidence.

Royal College of Physicians of London.

Society of Apothecaries of London.

The following candidate passed the necessary examinations and has been granted the L.S.A. Diploma of the Society, entitled him to practise medicine, surgery, and midwifery:—G. B. Holland.
NOTICES TO CORRESPONDENTS. &c.

Correspondents requiring a reply in this column are particularly requested to make use of a Distinctive Signature (or initials), and to enclose a stamped, addressed envelope.

"Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be avoided if attention is drawn to these pecuniary terms.

Reigning articles appearing in this Journal may be had at a reduced rate, providing authors give notice to the publisher or editor before the copy has been distributed. This should be done when returning proofs.

Owing to Bank Holiday there will be no Irish Supplement with this week's issue.

F. C. (Carlisle).—The address of the writer of the paper referred to is Nancy, France.

N. G. F. W. (Quebec).—The senior members of the staff of the Medical Journal were full of praise of the Irish hospitals and the surgeons mentioned by our correspondent, and not likely to be the damper. The answer to the question in the negative.

Iniquity.—The X-rays are a valuable means for confirming a diagnosis of cancer of the stomach. A recent authority has stated that in a hundred consecutive cases in 87 per cent. a definite diagnosis of the disease was established.

G. P. (York).—A recent suggestion in the treatment and prevention of bed sore is spousing the part with a 1 to 50 solution of creosote in alcohol.

County Surgeons.—The only dignified course to pursue is the purely scientific. Apart from and beyond that our correspondent would expose himself to retaliation, which would be harmful to his health.

SCIENTIFIC RESEARCH FOR THE LOCAL GOVERNMENT BOARD.

The President of the Local Government Board has authorised the following researches to be paid out of the annual grant voted by Parliament in aid of scientific research and the investigation of diseases respectively.

These are in addition to the investigations already announed.

1. An investigation in the details of the technique in carrying out Wassermann's reaction for the diagnosis of syphilis. The Army Council have consented to give Mr. Rufus Horrocks, M.R.C.S., the necessary assistance to carry on the research.

2. An investigation by Mr. H. J. Grauvink, in collaboration with the Board's pathological staff, of certain cutaneous tuberculous reactions, and the possible use of these reactions as an index of the presence and virulence of the disease. This work is being carried on in connection with the Royal Society of Medicine.

3. A continuation of the investigations of Drs. Twort and McIndoe on infantile paralysis, with special reference to the conditions governing the absorption of toxic substance from the alimentary canal.

A further investigation into the causes of still births by Drs. C. J. Lewis and Dale.

P. A. (Retford).—From some recent observations by Dr. D. J. Thomas, Medical Officer of Health of Stepney, it appears that pulmonary tuberculosis is more common among Jews than others, and that the Jews have a higher death-rate. The death-rate in this disease in Whitechapel last year was more than 1,000 in the rest of the borough.

T. H. (The Hague).—The matter was discussed at the recent Aberdeen meeting of the British Medical Association, when many speakers in the field of tuberculosis discussed the value of giving elementary instruction upon sex hygiene to older scholars.

J. T. S. (South Shields).—Our correspondent is advised not to accept any letter of our quills for the certificate and examination.

Dr. M. G. (Kent).—The symptoms are certainly suspicions of neumonia, but in the absence of any definite microscopic finding the diagnosis must remain for the while in abeyance. The Wassermann test, when the disease has been diagnosed, might throw further light upon the nature of the swellings.

Vacancies.

Hulme Dispensary, Dale Street, Stretford Road, Manchester.—House Surgeon. Salary £150 per annum, with apartments, attendance, etc. (Applications to Honorary Medical Officer.)

Certifying Factory Surgeon.—The Chief Inspector of Factories recommends the following appointment.—Gargrave (York).

Swanage General Hospital (106 beds).—House Surgeon. Salary £120 per annum, with board, washing, and attendance. (Applications to W. D. Hughes, Secretary.)

Surgeon, Manchester Infirmary.—Salary £175 per annum, with board, salary and duty, and appointment to Honorary Medical Officer. (Applications to W. P. Atkinson, M.R.C.S., L. M.D.)

Sheffield Royal Infirmary.—Surgeon, Assistant—Salary £125 per annum, with board and residence. (Applications to Mr. Frederick Gill, Secretary, H. Norfolk Row, Sheffield.)

Bolton Infirmary, Barrow.—House Medical Officer. Salary £120 per annum, with board and residence in the Infirmary. (Applications to E. Lambey Fisher, M.D., Secretary, Bolton Infirmary.)

Greenfield Infirmary.—Assistant Surgeon. Salary £120 per annum with residence, board and salary. (Applications to the Hon. Secretary.)

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £150 per annum with apartments, attendance, light, and fuel. (Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.)

West Riding of the County of York: Storthorpe Hall Asylum, Kirkburton, near Huddersfield.—Assistant Medical Officer. Salary £230 per annum, with furnished rooms, board, attendance, and washing. (Applications to the Medical Superintendent.)

Southwark Union, London.—Third Assistant Medical Officer. Salary £120 per annum, with board, lodging, and washing. (Applications to Mr. George Wood, Clerk, Union Offices, Old Kent Street, Blackfriars, S.E.)

Appointments.

Gladstone, George, M.R.S., B.S., London, Curator of the Museum at the Royal Free Hospital.

Mills, C. M., M.R.C.S., L.R.C.P., Honorary Assistant Medical Officer to St. Paul's Hospital for Skin and Genito-Urinary Diseases, Red Lion Square, London.

Nelson, A. W., M.D., Medical Officer, Assistant-Surgeon of the Naval Hospital, Greenwich.

Platt, C. W., M.B., B.S., London, Principal of the New Queen Mary Medical College at Delhi.

Savoyon, W. H., M.R.C.S., L.R.C.P., Medical Officer to the King Edward Memorial Hospital, Ealing.

Births.

Collingsford.—On July 31st, at "Goldcote," Goodurst, Kent, the wife of W. E. Collingsford, M.R.C.S., of a son.

Crawford.—On Sunday, July 31st, at 113 Albany Street, Regent's Park, N.W., Dr. and Mrs. J. C. Craig—a son.

Griggs.—On the 24th inst., atkinson House, New Abbey, Brixton, the wife of Hugh Gillies, M.R.C.P., of a daughter.

Harvey.—On August 1st, at "Brookside," Great Shelford, near Cambridge, the wife of Alfred Price Green, M.R.C.S., L.R.C.P., of a daughter.

Hussey.—On July 28th, at St. Mary's Church, Tynwald Park, St. Peter, Alfred Dunia, M.R.C.S., L.R.C.P., L.D.S., Surgeon and Physician to St. Thomas's Hospital, Down, of a son, to Eliza Beatrice, elder daughter of Frederick Taylor, of Guy's Cliff, Elmbank Road, Clifton, and Delphine S. Scott.

Murphy—Goodlife.—On July 30th, at Corpus Christi Church, Montreal, the wife of Dr. Francis Murphy, L.R.C.P., and E. S. Ed., of St. Paul's Norbury, S.W., to Ada Margaret, youngest daughter of the late W. F. Goodlife, Little House, Bound.

Marriages.

Belfast—Gealrath.—On July 29th, at Holy Trinity, Brompton, Joseph Dudley Be inefficient, M.D. of 60 Wimpole Street, Oxford Street, son of J. Be inefficient, of 71 St. Albans Street, Regent's Park, senior to Elvera Helen, elder daughter of Gustave C. E. Gealrath, Folkestone.

Bromley.—On July 29th, at Colney Heath Church, Herts, Trevor Lawrence Bomford, Capt. Indian Medical Service, eldest son of Capt. George Bomford, M.A., C.M.S., Poole, to Winifred Dora Greene, eldest daughter of Alfred Price Green, M.R.C.S., L.R.C.P., of Tooting Bec, S.W., of Tooting Bec, S.W., of St. Mary's Church, Tynwald Park, St. Peter, Alfred Dunia, M.R.C.S., L.R.C.P., L.D.S., Surgeon and Physician to St. Thomas's Hospital, Down, of a son, to Eliza Beatrice, elder daughter of Frederick Taylor, of Guy's Cliff, Elmbank Road, Clifton, and Delphine S. Scott.

Mrs.—Beach.—On July 30th, at Corpus Christi Church, Montreal, the wife of Joseph Dudley Be inefficient, M.D. of 60 Wimpole Street, Oxford Street, son of J. Be inefficient, of 71 St. Albans Street, Regent's Park, senior to Elvera Helen, elder daughter of Gustave C. E. Gealrath, Folkestone.

Deaths.

Bate.—On July 31st (suddenly, at Christchurch, Hants, Albert Brook Be inefficient, M.R.C.P., fifth son of the late Joseph Be inefficient, of Holdenhurst, Dursley, and 60 Wimpole Street, London, son of John Ross, Q.C., of Toronto, Ontario, and Ada Myers Ward, of 71 St. Albans Street, Regent's Park, senior to Elvera Helen, elder daughter of Gustave C. E. Gealrath, Folkestone.

Mrs.—Beach.—On July 30th, at Corpus Christi Church, Montreal, the wife of Joseph Dudley Be inefficient, M.D. of 60 Wimpole Street, Oxford Street, son of J. Be inefficient, of 71 St. Albans Street, Regent's Park, senior to Elvera Helen, elder daughter of Gustave C. E. Gealrath, Folkestone.

HULME DISPENSARY.

Dale Street, Stretford Road, Manchester.

WANTED A HOUSE SURGEON duly registered and fully qualified. Salary £150 per annum. Annual increase £10 to £20. Address, with examples, to once to Honorary Medical Secretary.

HUMBLE DISPENSARY.
Since the day of our last issue—seven brief days ago—history has been made at an unprecedented pace. At that time war had already been declared amongst four of the largest and several smaller Continental powers. For the protection of the honour and safety of the British empire and her friends our government declared war against Germany at 12.15 a.m. on the morning of Wednesday, the 5th August. That declaration has been followed by prompt and decisive action. The British army and navy have been mobilised; £100,000,000 was voted unanimously by Parliament; Lord Kitchener was appointed Secretary of State for War, and his request for 500,000 additional men in the army granted; portions of the country have been placed under martial law, and it has been resolved to send out an expeditionary force to the Continent. As might well be imagined, a warlike movement of this magnitude must shake the social structure more or less to its foundations. So far the nation has responded to the test with that cheerfulness and steady confidence which characterise the insular character in time of stress, and in this instance, stand recorded for ever in the vast rush of our countrymen of all ranks to join the colours and fight for King and country.

Is the Emperor William Sane? The fact that it should be possible for any single human being to hold at his mercy the lives and fortunes of many millions of his fellow-creatures in itself presents a standing satire upon the collective wisdom of the peoples of Europe. As to the Emperor himself his conduct has for many years past been that of a versatile, arrogant and eccentric man—obsessed by an exaggerated view of his own powers and his place in creation. His recent acts are of such a nature as to suggest that he has lost the higher mental control that constitutes sanity. To challenge Russia alone was to engage in a formidable task, but what can we think of the mental condition that has prompted him in addition to attack France and Belgium, to defy and to force the British nation into war, to say nothing of various other provocative acts in connection with the Triple Alliance. The picture of this one man engaging half Europe in mortal combat suggests the grandiose delusions and conduct of a man who in private life would probably be called upon to undergo a careful scrutiny of his mental condition.

So far as the medical profession is concerned the immediate effects of the war have been already profound and far-reaching. Under the army organisation methods of Lord Haldane a large number of medical men are liable to service in the Territorial Force, and many of them have been already called upon to join, while others may be ordered away at any moment. Many men on the staffs of the hospitals—both honorary and resident—have left for active service, and not a few of the huge general hospitals are left without adequate medical service, and in some instances patients have been sent back to their own homes so as to relieve the pressure upon the wards. Nurses have also been requisitioned, and as the war is on a large scale the extent and gravity of which is impossible to foretell, the property upon the medical profession in the United Kingdom is likely to continue for a long time. Not only is there an absolute shortage at the present moment in all classes of public and private medical practice, but the war is absorbing all the floating margin of qualified practitioners available, as well as senior medical students who are invited to join the Army and Navy as dressers. A large number of commissions—military and naval—are offered to medical men under 40 years of age.

The financial aspects of the war naturally present a serious problem. The credit system which governs the ordinary business transactions of the community is subjected to a severe strain by the disturbances consequent upon our International war. It is probable that our great grandchildren will have to stand the burden which is now forcibly thrust upon the present generation. It seems not unlikely that a great deal of loss will be inflicted upon the medical profession, both by reason of the service which they will in many instances loyally render to the State and, indirectly, by the lessened capacity for payment of fees by the community. The issue of one pound Bank of England notes is one of various precautions taken by Government to relieve financial tension. It is interesting to note that in the Napoleonic wars which culminated at Waterloo a century ago, notes were issued of the face value of one guinea, a sum that still survives in the customary fee of the physicians of our own day.

The Free Death Certificate. A coroner's jury at Sheffield recently put on record its views as to the probability upon medical men charging for a death certificate. Some interesting points were raised in the course of the inquiry. The inquest was held because of the vague nature of the statement as to
cause of death, which was returned as "syncope." The document thus filled in was accepted by the Registrar upon learning that deceased, a panel patient, had been under medical treatment for two weeks before death. The coroner's attention was drawn to the fact that, to the unsatisfactory nature of the medical attendance, an inquest was held, and it was shown by post-mortem evidence that deceased was in a late stage of Bright's disease. The coroner pointed out the unsatisfactory nature of the death certificate, as syncope or heart failure meant little or nothing in that connection. The medical man said that deceased lived in a single room with his wife, who was away at work all day. Deceased was in an indescribably dirty state, and never had his clothes off from the commencement of his illness to the day of his death. He urged deceased to go into the infirmary, where he could get proper nursing and attention, but his advice was not taken. Under these circumstances the calmness as the want of medical attention were practically dismissed by the coroner. As to the charge of one shilling for the death certificate, the person who paid it expressed his surprise that a fee of the kind was asked from a panel patient. Needless to say, the local coroner attests that he is to grant a death certificate without fee. A medical man has no right to demand it as a right, although there is nothing to prevent him asking for and accepting a fee for the service in question. It certainly is not usual to charge for a death certificate from persons in such a state of poverty as deceased.

A courageous Inquest.

The most striking point raised in the inquest is the fact that the coroner held it because the return of the cause of death was vague and unsatisfactory. His action we approve, as it seems tolerably clear that without some system of critical control of the kind it would be impossible for him to discharge his function of inquiry into unnatural deaths. In doing so, however, he has shown considerable courage, for the average coroner errs in the opposite direction, and holds as few inquests as possible. In that course he is prompted, naturally enough, according to his temperament and special environment, by considerations of a personal nature, and by the constant pressure he is under to save the ratepayer. There is much too, I think, of the kindliness of the practice of paying coroners pro rata with the number of inquests actually held—that is to say, from the point of view of public safety. Another fact of vital importance to the community is the acceptance by the local Registrar of a certificate of death filled in with so worthless a primary cause of death as syncope. It is obvious that such a certificate would cover murder, abortion, suicide, and a variety of other violent and unnatural deaths. It is high time that local Registrars were duly informed of the precise nature of their duties, and were kept to a proper standard of administration by a local coronet or some authority at Somerset House. Under present conditions the Registrars are innocent, but none the less powerful, friends and confederates to a whole host of quacks, charlatans and evil-doers of various kinds. In the particular inquest under notice it is clear that the acceptance of such a certificate as that challenged by the coroner provided a loophole for more than one kind of criminal or otherwise unnatural death.

Dr. Arthur James Milne, M.B., B.S., Aberd., has been appointed Assistant Medical Officer of Health for Johannesburg at a salary of £250 per annum, with an allowance of £15 per month towards the upkeep of a motor car.

THE MEDICAL PROFESSION AND THE WAR.

Another "page of the great book of war," happily closed to our ken for the last fourteen years, has been ruthlessly disclosed to view. It is scarcely more than a week ago that many members of the medical profession were quietly discussing in congress some of the problems incidental to their daily practice. Now all is changed, for the call to arms has resounded through the length and breadth of the land. Things have moved with such startling rapidity during the past week that large numbers of medical men have relinquished their ordinary work and taken up active service with the Forces to place their skill at the disposal of the sick and wounded. Many civilian practitioners and senior students have likewise offered their services, and to the credit of the rank and file of the profession be it said that every name upon the Medical Register stands for a personality that is willing to efface its own feelings and desires in responding to humanity's cry for help. Being prepared for emergencies at all times, the medical man who obeys the call to service is taken by surprise, less, perhaps, than any other member of the community, not even excepting the soldier. In one sense it cannot be called a surprise at all, for it matters comparatively little whether the patient be lying upon a stretcher, or prone upon the battle-field, or in a comfortable bed. The surgeon with the Forces is simply carrying on his ordinary life work, that of relieving pain and suffering, under different surroundings to those to which he is usually accustomed. This is neither the time nor the place to magnify the office of the medical man, but it may be mentioned as one further instance of his readiness to work without fee or reward that the practitioners upon the London panel have agreed to provide free treatment for the dependents of reservists who have been called upon to serve their King and country in this time of need. It is impossible yet to tell how great the demand may be for medical assistance, both at the front and also in the base hospitals, so that the likelihood of a further depletion in our ranks at home has to be faced. One suggestion has been made in view of the present emergency which seems to be quite practicable—namely, that all candidates who have recently failed in their final examination for medical degrees or diplomas should be re-examined at once in their weakest subjects, and, if they pass, be allowed to receive their qualifications; and also that all those candidates who failed by narrow margins, and who are anxious for active service, should be let through at once. All delay is dangerous in war, and no stone should be left unturned for a moment whereby the efficiency of the medical service may be increased. Past experience in warfare has demonstrated the importance of forethought and attention to detail in the matter of organisation and equipment. The medical apparatus of war, if more costly than

THE MEDICAL PRESS. 161

War and the Social Sense.

Socrates once said that man was a generous animal. So he usually is—under compulsion. Our tendency seems to be that of units which have got together somehow and have then developed a psychic centrifugality. Each man tries to escape from the influence of his fellows as much as he can. The aim of everybody is "to live his own life," and the only established convention is unconventionality. It is true that the powers in being assault us in assembled abstracts and overwhelm us in outrages of classification pro forma, but the very might of their insipid coercion is the measure of our innate opposition. Our lives announce that we are individual with the universal corollary of injusticability. In these countries we have been learning to disrespect the law per se, and our ambi-

that of half a century ago, has the advantage of being more portable; and, further, the sick and wounded will benefit as a result of the practical application of recent scientific discoveries in medicine and surgery. It has been urged, and rightly so, that every man in the services who has not already submitted to anti-typhoid inoculation should be so protected at once, for there can be no doubt as to its power of producing immunity against one of the greatest scourges of armies in the field. Turning our attention once more to home matters, it is feared in many districts, owing to the shortage of medical men which will, necessarily, be experienced, that the poor will suffer in consequence. A little readjustment all round of medical appointments, together with the unsellish co-operation of local practitioners, will, no doubt, readily combine to render the present changed conditions easier to bear, and to smooth the lot of the sufferers at our own doors. Most, if not all, of the hospitals are fully alive to the exigencies of the situation, and are prepared to receive soldiers and sailors, wounded or invalided from active service, during the war. Many other buildings have also, we understand, been placed at the disposal of the Government or of the British Red Cross Society for a similar purpose. Ours is, we believe, a righteous cause, and justice is the rightful sovereign of the world. In the meantime our readers will wish God-speed to all medical men and nurses who have nobly placed their services at their country's disposal in the sacred cause of humanity. God Save the King!

HORMONES AND THEIR PHYSIOLOGICAL BEARINGS.

The discovery of those curious and interesting bodies, the hormones, has had much the same disturbing influence on current theories of organic life as that of radium on our conceptions of the physical constitution of the universe. Hormones, be it remarked, have been defined as "substances in solution which, conveyed from one organ to another through any of the liquid media of the body, effect a correlation between the activity of the organ of origin and the organ on which they exert their specific effect." The hormones, however, are bodies which are most satisfactorily observed in their effects, and one of the best known is secretin and its immediate predecessor pre-secretin. It was observed that the introduction of dilute hydrochloric acid into the digestive canal was followed by a remarkable increase of the secretion of pancreatic juice. Subsequently, Starling ascertained that this was not due to an "acid reflex," as suggested by Pavlov, but to the action of the acid on a previously unknown body to which the name secretin was applied. Secretin, as produced, is conveyed by the blood to the other digestive organs, in which it sets going certain functions. Now secretin is produced, apparently, when the acid contents of the stomach come into contact with the pylorus and duodenal walls; consequently, when the acid is deficient, the supply of secretin falls off, and the subsequent steps in digestion, lacking their normal stimulus, are imperfectly performed. This explains many previously obscure points in the rhythm of the organic functions. It was supposed, for instance, that the administration of hydrochloric acid, and substances such as meat extractives which excite the secretion of hydrochloric acid, assisted digestion merely by providing the acid medium required for pepsin to produce its maximum effects, but these data show that the influence of the acid is more far-reaching than this, since it not only regulates the propulsion of the gastric contents into the duodenum, but also unlashes the internal secretions which set the rest of the digestive machinery in movement. This fact is interesting in view of some observations made by Beveridge, of New York, in respect of the action of lactic bacilli on the production of secretin. Apart from a deficiency of acid the other causes interfering with the normal production of secretin are intestinal putrefaction, ulcer of the duodenum or pylorus, and any lesions involving the mucosa of the duodenum and upper part of the small intestine. It would seem, therefore, that the good effects which follow the lactic ferment treatment are due not only to the fact that it inhibits intestinal putrefaction, but in part also to acid stimulation of secretin production by the lactic acid, which is a normal product of these ferments—a sequence of events which opens up a wide field for observation. This suggests a fresh departure in functional therapy, for it seems probable that in the near future, instead of endeavouring to supply the particular ferment which we imagine to be lacking, we shall aim at isolating and utilising the soluble principles which unlock that particular function. It is by no means unlikely that the therapeutic effects of some of the ferments which are currently administered are, in part at any rate, due to a subtle influence exerted by them as hormones when absorbed into the blood current. The importance of this discovery is enhanced by the fact that the hormones do not appear to be specific to particular organisms, but are chemical stimuli acting on the particular function, or rather organ, whether in man or animals.
tion has been to live out our life as the light. Now we have changed. The trumpet has done that. The call to keep up our end at Armageddon has woken the social sense. The phenomenon is a psychologically interesting one. It is outside our experience to find the majority of men consciously and disinterestedly working for the common good, where that good clashes with their interests as individuals. That is the way of a man's making congratulation. The rapidity with which we have put away our differences—differences that a few short days ago seemed hopelessly irreconcilable—may make our everyday convictions seem somewhat insincere. That is the superficial view. We may be sincere about a cricket match but we can put away thoughts of rivalry when the moon comes; and so with greater issues. As men of science are citizens of the whole world, we must remember that though patriotism is great, humanity is greater. At this crisis our way is plain. We trust and believe that the interests of patriotism and of humanity are identical. Our way lies straight before us. We must tread it mightily.

The Hygienic Value of Paper.

It is hard to realise, in our advanced state of civilisation, the consequences of being deprived of what has, hitherto, been regarded as one of the necessities of life. The rumours of a shortage in the supply of paper to this country on account of the war causes one to reflect upon paper and paper-making itself. Not until 1858 was the art introduced into England, but it is only within recent times that the possibilities of paper as a material of some hygienic advantages have been recognised. In an interesting paper upon the subject read at the Congress of the Royal Sanitary Institute at Birmingham last month by Dr. S. Ridley, D.Sc., the use of paper is recommended for home articles in daily use which require frequent washing. It is suggested that such moveables as plates, cups, and even dustbins, should be made of paper and destroyed when soiled. The use of paper handkerchiefs has been advocated for consumptives for some time, and the paper serviette has come to stay. The ordinary housewife, we fear, would think twice before being beguiled into substituting paper blinds, curtains, table-covers, and towels in place of ordinary linen goods, sanctioned by custom and tradition. They might obviate danger of infection, being rendered non-inflammable they would be highly dangerous. The use of paper disinfesting bags containing formaldehyde, for dealing with infected clothes, etc., described by Dr. Munson, appears to solve some of the problems of domestic infection, whilst these receptacles are of service as emergency disinfectors for army use. If paper-kag cookey is not always practicable, there must be several ways in which the more extended use of paper should appeal to medical men and sanitarians on hygienic grounds.

Back to the Brand.

The Medical Officer points out that in some ways our ancient communities are merely copying unconsciously their forgotten ancestors. The idea of placing a distinctive sign on the dwellings of those suffering from an infectious disease has existed from time immemorial. The Jews of old did it, and in our own country, when the great epidemics of the black death and the plague swooped down, people were put to flight or were compulsionarily put on the doors of every stricken house. America has just learnt of the scheme and is adopting it with a touching and whole-hearted enthusiasm. Every State in the Union but nine has legalised "placarding." The circumstances of its use are vague and local, as is the exact manner of its issue and the principle is there. Is it a red and white placard or a yellow flag? No matter, the notice to all whom it may concern is branded on the building, and must not be removed till the sanitary authorities have poured their first libation to Lister. In some districts where the passion for information outweighs the citizen's fear of infection he may be the kind of infection he is to keep away from by the colour of the housing. But that is luxury. The fact remains that the United States have revived an old custom and have found it extremely valuable. In England the system is adopted only by a few districts, and we are not aware that it has been of any great benefit to those concerned. Still it is interesting to see a people which prides itself on its up-to-dateness enthusiastically resurrecting an old custom long given up by the generality of its originators.

Maternity and Child Welfare.

Much attention has been paid of late years to infant welfare work, both by local authorities and also by various private agencies. Hitherto the efforts of these bodies have been largely concerned with the child in the first year of its life, but there is no reason, of course, why their scope should not be considerably extended so as to embrace the whole period from before birth until the time when the child is entered upon self, si, and other happiness. The Local Government Board has recently issued a circular to county councils and sanitary authorities with regard to an estimate that has been laid before Parliament for a grant to be distributed by the Board in aid of the expenditure of local authorities in securing agencies in respect of institutions or other provision for maternity and child welfare. It is pointed out that more extended and systematic efforts are needed to deal with this matter, and that it is desirable to arrange for medical advice and, where necessary, treatment for expectant mothers and mothers after the child is born. In an accompanying memorandum it is suggested that a complete scheme should comprise certain elements each of which may be organised with special reference to infantile welfare. These include arrangements for the local supervision of midwives, an ante-natal and infant welfare hospital, or at least an ante-natal hospital, an infant nursery, and an accommodation for expectant mothers, a maternity hospital or beds at a hospital, in which complicated cases of pregnancy can receive treatment, in addition to such assistance as may be needed to ensure the mother having skilled and prompt attendance during confinement at home, or to send her to a suitable hospital. Finally, it is stated that provision should be made for the treatment of complications arising after parturition, for systematic advice and treatment of babies at a special clinic, and for the systematic home visitation of infants. The Board is willing to consider applications for grants in respect of any work falling within the scope of the above memorandum and it expresses its willingness to assist local authorities in the initiation of schemes or the extension of existing ones.

Smoking.

We die daily. Apparently the process is largely suicidal. We are always doing things we ought not to do, and we have forgotten are doing them for our own benefit. We eat, drink, and poison ourselves through our colon; drink, and line our arteries with lime; and are merry, with the most disastrous psychological results. And, of course, we smoke. We were always told it was bad for us. That is probably
why we ever wanted to do it. We are still being
told it is bad for us. Not in the simple downright
terms of our youth, but now it is the "lambent
pupillage of slow, low dry chat" that encourages
conviction. J. Pawinski has contributed a com-
prehensive study of the effects of tobacco on the
lung and bronchial tubes. He has shown that
the smoking of tobacco, whether to a moderate or
excessive extent, is injurious to health. In the

A young woman who has not menstruated for some time is seized with severe pain in the abdomen, turns pale, becomes faint, or even faints outright, and has a small, rapid pulse. If on exploring the abdomen we detect ill-defined resistance just above the pubes, and, on vaginal examination, a lax or uteri with an enlarged uterus, we can have little hesitation in making a diagnosis of uterine cancer. We are dealing with a case of ruptured tubal gestation accompanied by internal hemorrhage, calling for immediate surgical intervention.

Similarly, when a patient has been vomiting blood for some time, not in any great amount, but frequently repeated in spite of treatment, and recurring as soon as a return is made to ordinary food, reducing the patient to a state of extreme prostration, neither the physician nor the family have any hesitation. Anything rather than death from hunger.

Gastro-enterostomy, with or without resection of a gastric ulcer, is plainly indicated and commands assent.

Strangulated hernia comes into this self-same category. That is to say, the group of affections which call for instant surgical intervention.

But supposing we are dealing with a patient—1 mean a private patient, because the question virtually only arises in private practice—who presents a small ulcer of the tongue, say, the size of a bean, presenting the classical features of epiphelitis, viz., irregular margination and a greyish lustre covered with increasing debris, it is our duty to advise a radical operation, possibly accompanied by excision of the cervical glands, in fact, very extensive mutilation of the mouth and one or two big incisions in the neck. We shall have the greatest difficulty in getting the patient and his friends to act on our advice.

This is the sort of case which I propose to discuss, cases in which there appears to be a striking disproportion between the visible lesion and the gravity of the operation proposed for its removal. To begin with, the practitioner must be absolutely sure in his own mind that his diagnosis is sound and his prognosis correct. Then, too, it is well for the practitioner to imagine himself in the patient’s skin, so to speak; he must ask himself whether, under the circumstances, he would consent to undergo the operation he is advising. He need not feel hurt should his counsel be rejected, since, if he be sure of himself, he has only to wait patiently for the future to establish the correctness of his attitude. If he does not feel quite sure of himself, then no doubt he is justified in feeling uneasy, because the subsequent course of events may not bear him out. He must be sure of himself, because, should the operation not yield the hoped-for result, or should the patient fall victim to some operative incident, it is nearly always on the practitioner that the blame falls rather than on the surgeon.

Naturally, brought face to face with the prospect of a grave operation, the patient and her friends are but too likely to look round for a loophole of escape. Might they not try such and such a treatment first, seeing that it answered very well in the case of an acquaintance “suffering in the same way,” or the quasi-miraculous serum of which they have read so much in the papers. The well-advised practitioner will no shrug his shoulders and abruptly refuse to discuss these alternative methods. He must try and explain to persons, for the most part ignorant of medical matters, that in this particular instance the treatments they suggest cannot, and will not, answer his purpose, and in simple language he must do his best to explain why this is the case. If he himself is sure of his ground he can generally convince them of the necessity for the operation.

But let me refer to a few instances of cases calling for these grave decisions. A man between 40 and 50 years of age is seized with violent pain during the night in one eye; the pain radiates round about the orbit, in the forehead, over the corresponding half of the head, and soon becomes absolutely intolerable, while pari passu vision becomes dim. The conjunctiva is red, injected and edematous, the pupil dilated and sluggish, the iris dull, and the globe, on palpation, feels of wooden hardness. Obviously it is a case of glaucoma, and only prompt iridectomy can save the eye.

The patient is ready to consent to anything, so acute is the pain, but the family is often difficult to persuade, though, when given to understand that sight itself is threatened, they reluctantly acquiesce.

Mastoiditis is another condition in which grave decisions may have to be taken. Glaucoma menaces sight, but mastoiditis threatens life itself. A girl ten years of age has had running at the ear since an attack of typhoid fever at 6. There has been no pain to speak of until about a week ago, when she began to complain of tenderness behind the external auditory meatus coinciding with sudden arrest of the discharge. The pain tends to become worse and it radiates all over that side of the head, preventing sleep. Three days ago some swelling was first noticed behind the ear, the temperature goes up at night, and the little patient complains of feeling feverish.

When we examine the mastoid region it is seen to be red and somewhat swollen. The ear stands out rather more than usual, but the retro-auricular furrow is intact. Pressure on the mastoid prominence causes sharp pain. Evidently there is deeply-seated mastoid suppuration, and it must be opened up. Here we have only to point out that, if unchecked, it will go on to abscess of the brain, culminating in meningitis. Very seldom will the friends assume the responsibility of refusing an intervention.

The territory of the abdomen opens up a wide field to these disagreeable surprises. Chronic appendicitis, with its insidious onset, is the bane of this genus. The patient has been losing weight, he has become apathetic and displays a tendency to neurasthenia, his complexion is dull, earthy, his liver is somewhat enlarged and his conjunctiva are yellowish, the tongue is dirty and his appetite is poor. Of course, the patient and his friends only
too readily attribute these symptoms to overwork, to the need of a change of air, to "worry," but the practitioner, who finds nothing to account for the loss of flesh in the lungs, heart, or to the patient's antecedents, turns to the abdomen. Might it conceivably be a case of chronic appendicitis? The patient is quite certain that he has never had any pain in the right flank fossa associated with nausea or sickness. But pressure over MacBurney's point reveals some muscular rigidity; there is some tenderness to deep palpation. Stoop of the body is there chronic appendicitis. We have only to wait a while, visiting the patient at odd times, and if then we discover that there is still tenderness over the appendix and nowhere else, we may rely upon it that he is suffering from chronic appendicitis.

Now, just imagine the attitude of the family; they have asked you in just to advise as to diet in the case of a child whose stomach is upset. Instead of drawing up a dietary, you advise opening the abdomen. No wonder they protest! It will take a lot of explaining, especially as you are not in a position to assert that the danger is immediate, certain and inexorable. Still, it is your duty to insist.

While we are talking abdomen, there is another affection of an insidious type that deserves attention viz., chronic intestinal obstruction. The subject is generally one past middle life. He has been troubled for some time past with constipation, alternating with occasional attacks of diarrhea. The belly is distended and rather tender. At the present time there is no passage at all, and when he passed a little flatus, the pulse is rapid, but firm; the face is pale but not drawn. He has been sick once or twice, bringing up glairy or mucous vomit. He has been taking enemata and purgatives supplied by the local chemist, but all in vain. They are not positively anxious, but they recognise that the bowels must be cleansed to work, and so you are called in. But when, your examination over, you gravely suggest opening the abdomen as the only means of rescuing the patient from the jaws of death, when you invite them to choose between laparotomy, artificial anus, and enterostomy, well, it is for them a bolt from the blue. Your difficulty is increased by the fact that you yourself are in a position to be dogmatic. You do not know, and therefore cannot state, the exact nature of the obstruction nor the probable result of the intervention, apart from the mere relief of the obstruction. You are obliged to admit your uncertainty, but, all the same, you must insist on an operation.

The too, salpingitis; this, too, is a disease the only remedy for which causes many a woman much and dolorous surprise. I am, of course, not referring to the sudden, acute forms of salpingitis which, so to speak, throw the patient upon the operating table, but the slow, insidious forms which undermine the health, which render the sufferer a hopeless invalid subject to persistent discomfort, with intermissions, a condition which keeps her in bed, unable to walk or go up stairs, or, it may be, without serious abdominal pain. The patient loses flesh, menstruation is irregular and painful, digestion is upset, and her temper becomes uncertain and irritable. She longs on in hope that rest, injections and counter-irritation will get the better of her state, but you, the practitioner, know well enough that it is vain to pretend to get anything of the kind. Your knowledge tells you that there is a thickened cord, in all probability containing pus, which can only be got rid of in one way. You can detect its presence by digital exploration, and it is your duty to advise its removal. In nine cases out of ten you will meet with considerable resistance, but you must overcome it if your patient is not to fall a victim to neurasthenia and progressive organic depreciation, with the tomb as its goal.

But it is in certain forms of incipient cancer that the operation becomes of extreme urgency, and the operation must be severe to afford any reasonable prospect of durable success. In spite of recent discoveries, in spite of X-rays and radium, our duty is to advise a radical operation forthwith. Only too naturally the patient hesitates at the prospect of a severe, mutilating operation, but your duty admits of no compromise; it is all or nothing. You must not shrink from your duty; you must be frank, and, if necessary, brutal, for in your hands lies the patient's only hope of safety.

Unfortunately, there are certain forms of cancer in which, from no fault of the patient's, you come too late on the scene to be able to use your persuasive powers to advantage. Cancer of the uterine cervix, for instance, is not painful in its early stages, and by the time the symptoms command attention it may be too late.

It would be easy to prolong the list, but these few examples would show what responsibilities we are called upon to assume in the exercise of our profession. These grave decisions, in face of sometimes apparently trivial lesions, are not the least of the difficulties with which you will be confronted, and on your decision and firmness depend not only your own reputation, but the future of the patient.

Note.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Arthur E. Giles, M.D., B.Sc., F.R.C.S., Surgeon to the Chelsea Hospital for Women; Gynecologist to the Prince of Wales Hospital, Tottenham. Subject: "Diagnostic Aphorisms in Gynecology."

THE TREATMENT OF INOPERABLE CARCINOMA OF THE UTERUS BY APPLICATION OF HEAT. (a)

By J. F. PERCY, M.D.,
Galesburg, Illinois, U.S.A.

At the present time the treatment of cancer may be easily differentiated into two classes. The first of these is the operable, which applies almost wholly to early manifestations of the disease; and the second, the inoperable, which concerns us most at this time.

Inoperable carcinoma may be attacked through attempts to destroy the possible cause, by vaccines, toxins, serums, etc.; again, by attempts to change the pabulum by which the disease is permitted to progress, such as may be suggested by the theory advanced by Ehrlich, under the name of atrophemia. From the standpoint of the experimental laboratory, the above theories and the work based upon them widen our mental horizon, and stimulate our imagination regarding the whole field of cancer research; but we cannot apply them now, because their value is yet undetermined, and the particular pabulum, or food stuff, which Ehrlich presumes for growth, is not fully understood.

We do know, however, that the cancer cells can be destroyed by the same agents that will destroy

forms, the toxins of Coley and the vaccine of Otto Schmidt. The experiments of Bier (6) show that the intravenous injection of foreign defibrinated blood raises the body temperature, and this is true also of the use, in the same way, of colloids of gold, silver and copper. The observation of the older physicians, who noted the disappearance of malignant activity following infection by erysipelas, claims our interest in a new way. Pierre Delbert has confirmed the experiments of Vidal on the deleterious action of increased body temperature in mice.

Reduced to the simplest statement, our problem in inoperable cancer has always been two-fold: first, to get rid of the gross mass; second, to destroy the progressive metastases. The second point usually loses much of its significance in the overshadowing presence of the primary great mass. If what Vidal and others tell us is true, it is a rational procedure to attack these morbid masses with the aid of the method tending to raise the temperature of the whole body above 40 deg. C. (104 deg. F.) is impracticable, because dangerous. In addition, it is uncertain, and we cannot regulate it. We are compelled, then, to find some method more local in its application which will exert the greatest destructive process on the gross mass of cancer and that will produce at a minimum degree the normal connective tissue cells.

The only agents so far found worthy of consideration are hot air, hot water, steam, electro-coagulation, fulguration and actual cautery. Hot water, hot air and steam are shown by Doven to be of no practical value, because of their slight penetration. Electro-coagulation by its tissue effects will not produce anything of the kind of 5 to 8 cm. in two minutes. The rapidity of action, the difficulty of control of the electrode—the complicated apparatus necessarily, together with the refinement of technic and specialised judgment required of the operator, make this method impracticable in the treatment of the cavity carcinoma. The angi-Hart method of fulguration (7), i.e., the sparking from a high frequency current of high tension, after the surgical removal of the bulk of the mass, especially when superficial, is worthy of notice in this connection. In the hands of the originator, by preventing relapses, it has undoubtedly improved the statistics of operative methods in advanced cancer. In our own cases, however, such methods have been employed. Durig (8) and Grau, however, insist that the only beneficial result from fulguration is due alone to the heat, and not to any specific action on the tissue cells. It is only just to the originator of this method of using high frequency currents to state that he denies that this is the mode of action in his method. He insists that where heat is obtained in this way, it is due to the reduction in the length of the spark, replacing the tension by thermic effects, which is a mistaken use of fulguration.

The methods just enumerated, in the hands of their originators, have added much to our knowledge of cancer therapy. But the cases cannot be considered extirpation. The method is extensive, complicated and expensive. In addition, to be effective, it demands not only specialised knowledge, but a refinement of judgment that requires more than the average experience.

In the way of comparison, it has been my pleasure to suggest a practical method of applying heat which has none of the objections that can, with reason, be urged against the methods already enumerated. (a) The penetration of heat by this method can be definite, although perhaps crudely,
determined and regulated. Where the malignant process is at all accessible, this method has almost no limitations. The so-called apparatus is not only portable, but also inexpensive. I refer to the development of heat through a most efficient electric heating iron, which can be perfectly regulated by means of a rheostat, when applied to the involved tissue. With this electric heating iron and my water-cooled speculum, and the vaginal probe, maximum heat is obtained in the involved structures. More than this, the low degree of heat which my experiments show to be more effective than the intense heat already mentioned, can be maintained accurately. This low degree of heat does not burn up the cancerous mass, but merely makes it so hot that the hand of the surgeon, encased in a medium weight rubber glove, can hold it. When this degree of heat is reached and maintained for from ten to twenty minutes, the cancer cells are absolutely killed, while the normal tissue cells are not injured. The important thing is not to convert the pathohlogy into charcoal. The charcoal, or carbon, thus formed inhibits the further dissemination of the cancerous cells, but not beyond. More than this, when the pathology is converted into charcoal, drainage is prevented for a number of days. This permits of the absorption of a larger quantity of broken down cancer cells than the average of these patients can tolerate; and many of them die as a result of this mistaken method of applying heat. Carbonisation is produced by a cauterised point heated to a bright cherry red colour. Carbon inhibits the dissemination of heat. To overcome this, still greater degrees of heat are required, which are extremely difficult to control, endangering the rectum, the bladder and the ureters. In another publication (10) I have given the details of some experimental work which well illustrates the practical importance of this very important factor. The heating iron, when used through the water-cooled speculum, should not be hot enough to sear a pledge of white cotton, if laid on the heating iron even for half an hour. No smoke, no smell of burning tissues should issue from the speculum, as would occur if they were being destroyed. The external uterine wall should hear only a gentle simmer or bubbling, while the heating head is in the diseased mass.

My experimental work, and the operation itself, demonstrate that when this "cold iron" is applied to the affected tissues, not only is there much less destruction of normal cells, but a far greater dissemination of heat, sufficient to kill carcinoma. Cancer is destroyed when the temperature in the mass is raised to 50 deg. C.—55.5 deg. C. (122 deg. F.—131.9 deg. F.); while the vitality of normal tissues is not changed until the temperature exceeds 55 deg. C. to 60 deg. C. (131 deg. F. to 140 deg. F.). The basic idea, then, of this treatment—and this cannot be too often emphasised—is the production of a greater dissemination of heat in the gross primary mass of cancer. There is no other method, or technique, familiar to me that will influence in a destructive way so great an area of malignant tissue, with a minimum amount of harm to the uninvolved structures. This technique, in a tremendously effective way, destroys the primary malignant focus. With this accomplishment the newer methods—especially the X-ray—that have been shown to be of supreme value in the destruction of the small isolated foci, in or just outside of the pelvis, make a combination of effort in the management of these otherwise hopeless cases, most promising in its possibilities. From my experience, I am convinced that it is not always best to attempt to destroy, at one sitting, a large mass of carcinoma. These patients are rarely in the condition which invites local anaesthesia. The application of the heat, to a degree which devitalises the major part of the exuberant over-growth, and rids the patient of her local focus of mixed infection, produces within two weeks a surprisingly beneficial result. This is especially noticeable if cachexia has not been a marked symptom. A second, or even third application of heat is not only safer, unless the involved structures are small, but it gives the operator a much better opportunity to reach, finally, the outermost confines of the disease.

When my technique in the application of heat in these cases is decided upon, I would strongly advise against the use of the curette, or other operative measures, for the reason that the heat is distributed through the cellulitis of the pathological over-growth, which we wish to destroy. Heat does not encourage the extension of metastases, while the curette and knife do. Again, scar tissue is not formed after the use of the curette, but it is the usual sequel after the application of the heat; and I have yet to observe the redevelopment of cancer in a patient treated by this method. When the surgeon believes that a modern total hysterec tomy should be the operation of choice in the less extensive forms of uterine carcinoma, I know of no more rational procedure than the methods here outlined, which should precede the final operation, at least by three or four weeks. In a personal case, where this treatment was applied to an active, bleeding, vegetative-like mass, springing from the craterous edges of a practically destroyed cervix uteri, no evidence of carcinoma was found on serial section eight months afterwards, when the uterus and cervix were removed through the abdomen.

I shall leave the statistics of my results in the treatment of inoperable carcinoma for a future paper. All that may be said at this time is that I believe that a large number of cases, if not practically hopeless when first presenting themselves for treatment, will give approximately fifty per cent. remaining free from recurrence over five years. In addition, my work along this line convinces me that the limits of benefit to be obtained by the application of heat in inoperable carcinoma have not yet been reached.

I am working out a method by which the amount of heat entering both the pathological and normal tissues can be accurately gauged. With this, the degrees of heat in the tissues at various distances from the heating head can also be determined. This will make it more definite and accurately certain that the required temperature known to destroy cancer is entering the parts involved.

The management of complications, the most serious of which is the prevention of rather late hemorrhages, is a matter of importance. In fifty cases this sequel has followed in two private and in two clinic cases. Only one of these, a private case, has died from the hemorrhage. It will probably prove to be true that the uterine arteries, or, possibly even the internal iliacs, should be tied in every case immediately preceding the treatment by heat.

Mentioning these important problems growing out of the practical application of my method, I do not wish to be understood as minimising the great benefits which this technique has already given to a rather large number of otherwise hopeless cases of inoperable cancer of the cervix and body of the uterus; but rather to express the hope that further improvements which can only be made in the use of heat in cancer, a wider and wider application of this extremely valuable method may be found.
years and in different epidemics. In Germany peritonitis is less common than in America. Recent figures embracing 9,713 cases collected in England, Canada and the United States show that more than one-third of the deaths from typhoid were due to peritonitis. At Johns Hopkins Hospital there were 43 perfections in 1,500 cases, or 1 in 36. In the Pennsylvania Hospital there were 50 perfections in 1,948 cases, or 1 in 30. In the Royal Victoria Hospital, Montreal, there were 83 intestinal perfections in 2,917 cases, or 1 in 35 and two perfections of the gall-bladder. In the Montreal General Hospital there were 110 perfections in 2,494 cases, or 1 in 22.3 cases. In the Royal Victoria and Montreal General Hospitals it is sometimes quite impossible to admit all the cases of typhoid that apply. Only the more severe cases are taken in. Again, quite a number of cases are admitted after perforation has occurred.

In 15,221 collected cases there were 514 perforations, or about 1 in 31. Statistics show perforation to be more common in men than in women. The reason is not obvious. In children peritonitis is rarer than in adults.

PATHOGENESIS.

Chomel remarks "that the accident is sometimes the result of ulceration, sometimes of a true eschar, and sometimes it is produced by the distension of the intestine, causing the rupture of the tissue weakened by disease." In a specimen in the McGill Museum there are 10 perforations in the ascending colon and sigmoid, probably from distension. I have usually found the perforation near the base of a generally well-defined ulcer. In size it varies from a very small pinpoint hole to an opening the size of a lead pencil. Only rarely is it larger. It is always situated nearly directly opposite the mesenteric attachment.

While it is true that the perforation may occur at any point in the stomach, small or large intestine or in the appendix vermiformis, yet, fortunately for the patient and the surgeon, it is found somewhere in the terminal two feet of the ileum in an overwhelming majority of cases.

PROGNOSIS.

That a typhoid perforation not closed by the surgeon is always a fatal complication is as a rule a true statement. The only exceptions are those in which a perforation of the large bowel occurs between the layers of its mesenteric attachment. When this occurs an abscess develops, extra-peritoneally, and may subsequently be opened. In the single case in my series in which this occurred the fistula gradually healed. It is probable that all cases in which a perforation of the small intestine occurs into the peritoneal cavity prove fatal unless recognised and the opening closed. The duration of life after perforation in 134 cases collected by Fitz was as follows:

| Died on the first day | ... 37.3 per cent. |
| second day | ... 29.3 |
| in the first week | ... 83.4 |
| second week | ... 9 cases. |
| third week | ... 4 |
| in thirty days | ... 1 case. |
| thirty-eight days | ... 1 |

DIAGNOSIS.

It is easy to establish the fact that a considerable percentage of the mortality in typhoid is
due to perforation of the intestine, and also that a goodly number of these cases may be saved by early recognition of the lesion and its closure. The great difficulty is the diagnosis. To get the best results the accident must be recognised early and appropriate treatment be instituted promptly. Here is the great difficulty, the question of early diagnosis. Some of our standard text-books are misleading in their remarks on the diagnosis of typhoid perforation. If it will not be considered too presumptuous for a Colonial to criticise writers in the great educational centres of Great Britain, I would like to say that when a recent edition of Choyce's "Surgery" says that the symptoms that suggest perforation are the sudden onset of acute pain referred to the umbilicus or to the right lower half of the abdomen, with tenderness on pressure and muscular rigidity, most marked in the right lower quadrant of the abdomen, and that there is nausea and vomiting and other symptoms of acute infection, and when Howard in his "Practice of Surgery," issued this year, says the symptoms of typhoid perforation are sudden acute abdominal pain with collapse and fall in the temperature they fail to appreciate the difficulties that surround the question of the diagnosis of typhoid perforation. The occurrence of perforation is but seldom indicated by such well-marked, striking symptoms. Furthermore, a fatal peritonitis may develop in typhoid without any perforation discoverable at autopsy, as reported in the Munich autopsies and in various medical journals.

The first indication that a perforation has occurred is usually pain. It was present in 75 per cent. of this series of 83 cases and absent in 25 per cent. 75 per cent. of them had either sudden crampy pain or sudden persistent pain in the following regions mentioned in order of frequency: generalised, right lower quadrant, umbilical zone, left lower quadrant, epigastrium, and left hypochondrium. In 25 per cent. of these cases the pain was generalised or in the right or left lower quadrants. Often the pain will not be severe enough to impress upon the nurse the need of sending for the doctor unless she has been specially trained in a typhoid ward. An important point in the training of a typhoid nurse is to teach her to send for the intern whenever a typhoid patient complains of abdominal pain.

In 25 per cent. of cases not having pain at onset, the following conditions were found:—

In 11 per cent. toxemia obscured all signs.

4 per cent. the condition was obscured by severe concurrent hemorrhage.

4 per cent. were not diagnosed.

1 per cent. had chills.

2 per cent. had rigidity.

4 per cent. had vomiting.

In regard to time, 62 per cent. occurred at night and 38 per cent. in the daytime. 4 per cent. of the cases had definite profuse sweats immediately after the perforation.

The symptom that I would place second because of its constancy and significance is change of expression. The change of appearance in a majority of the cases was quite evident. 65 per cent. showed a very definite alteration, 28 per cent. a gradual change, and 7 per cent. no change. This change in appearance was manifested in a picture of suffering from pain, a sudden pallor,
Those who have seen many typhoid perforations will appreciate Fitz's statement that perforation of the intestine in typhoid fever may take place without any suggestive symptoms and that suggestive—even so-called characteristic—symptoms may occur without any perforation having taken place.

In the text-book perforations diagnosis is easy, but if we are to save a large percentage of these unfortunate patients we must detect the accident in its most insidious form.

Again, it is not necessarily a reflection on the diagnostic skill and sound judgment when the abdomen is opened after careful consideration of the symptoms present by two or three clinicians and no perforation is found. It would seem that this may happen occasionally if conscientious attempt is made to recognise perforation as soon as it occurs. One case is on record in which the abdomen was opened twice in the same patient without finding any perforation! The same abdomen was later opened a third time, the perforation found and the patient's life saved. We cannot always afford to wait in these cases until the diagnosis is absolutely definite and assured.

What symptoms call for immediate abdominal incision, or, rather, what are the minimum signs that may demand surgical intervention? Pain, persistent; definite change for the worse in the expression of the patient; tenderness either abdominal or rectal; rounding up of the abdomen; and increased resistance to pressure. If these symptoms are present, even if the temperature and pulse are not decidedly altered, nor vomiting present, the likelihood of a perforation is very great.

Local anaesthesia has very materially altered our attitude towards early operations. It is no longer necessary to administer a general anaesthetic. The abdomen can be quite well opened under local anaesthesia without causing the patient any pain whatever. The closing of a typhoid perforation is one of the simplest operations in surgery; one that can quite well be performed by anyone capable of carrying out a perfect surgical technique. A 1 per cent. solution of novocaine with the addition of two drops of adrenalin to the drachm is thoroughly satisfactory and may be used freely. Insert first the skin and subcutaneous tissues, then, with a short needle one inch long, penetrate the deeper muscular layers along the line of incision. Either a gridiron incision or one along the outer border of the right rectus answers admirably. The perforation is nearly always found in the terminal 12 or 24 inches of the ileum. It is very easily found. A couple of through and through sutures usually suffice to close the opening and then one or two rows of fine Lambert suture complete the operation on the intestine. The patient should always look for a second or possibly a third perforation. These are seldom found, but not uncommonly some of the ulcers in the neighbouring portion of the ileum will present a very thin, necrotic-looking base. It is a good practice to infold such with a single row of Lambert sutures as a precaution against further perforation occurring after the abdomen is closed. Resection of an ulcerated portion of intestine in typhoid is rarely indicated, and should be reserved for the skilled operator and unusually threatening cases.

When the abdomen is opened the presence of perforation is generally made clear by the presence of fluid, lymph, or the escape of a little gas. Should none of these evidences be observed, do not close the abdomen without examining at least the terminal two feet of the ileum. It may be that a small pin-head perforation is temporarily closed by a tag of omentum. I have in this condition been in the direst of cases. Of course, such cases give a most favourable prognosis.

The percentage of recoveries is gradually increasing. Von Layden in 1884 suggested that the only rational way of treating perforations of the stomach and intestines was surgical. In the same year Miculicz closed a typhoid perforation. The patient, a man, act. 40, recovered. Fourteen years later, Keen collected 83 cases with a recovery percentage of 19.36. In the Royal Victoria and Montreal General Hospitals, 710 perforations have been closed and 38 have recovered, or 27.14 per cent. These figures include the work of all the surgeons attached to the hospitals. The figures are not large, but I think they represent 38 lives saved. The other cases of perforation were not operated upon for three reasons, chiefly, viz., not diagnosed; desperate conditions that offered no chance of success; and refusal of patients, parents or guardian to allow any operation.

It is sometimes very discouraging, and, of my first six cases died and then I became ready to give up. I succeeded in saving my seventh case and from that time recoveries have occurred more and more frequently. From January, 1909, to June, 1914, I closed 22 typhoid perforations, and 11 recovered, or 50 per cent. An important point is to let the house staff feel that it is a reflection on their professional attainments to overlook a perforation. When once they really appreciate that fact cases are sent to the operating-room promptly.

THE TRANSMISSION OF FOOT AND MOUTH DISEASE TO MAN.

By Prof. E. Boismoreau, M.D.,
Of the Faculty of Medicine of Paris.

[Specially Reported for this Journal.]

It is perhaps not generally recognised that foot and mouth disease in animals is capable of transmission to human beings, and as I have happen to have had special opportunities of witnessing the supervision of the disease in man in the course of a widespread epidemic in animals I think it worth while to place the facts on record.

The epidemic started in 1912, and although certain precautions were enforced it spread far and wide, attaining its maximum intensity in July and August of that year. It was then that I met with cases in my practice and I cannot do better than reproduce my notes:

CASE I.—An infant, act. 15 months, was brought to me in August, 1912, on account of some difficulty in swallowing which led it to refuse food. Methodical inspection revealed nothing of any particular interest beyond a little bronchitis, but the rectal temperature was 105.8°F. Turning my attention to the buccal cavity I noticed at once that the gum, mucous membrane and tongue were the seat of a vesicular eruption, the vesicles being rounded in shape with a pink base. Some of them had ruptured, leaving tiny ulcers the floor of which was yellowish white. The ulcerated surfaces were very tender to the touch, the breath was very offensive, and the mucous membranes...
appeared to be thickened. I counted upwards of thirty of these vesicles. The submaxillary glands were slightly swollen and tender and the urine contained a trace of albumen.

I touched the ulcers with chloride of zinc and administered anti-diphtheritic serum by the mouth. Improvement set in the day after commencing the treatment and recovery ensued in four or five days.

The injection appeared to have been conveyed by milk from cows that had recently been suffering from foot and mouth disease, in spite of the fact, stoutly maintained by the mother, that the child had taken no milk that had not been boiled.

Case 2.—Man, 3t. 35, agricultural labourer, had been attending sick cattle, but had not drunk any milk. Temperature 100.8° F. Complained of headache with pain in the back and limbs. The mouth, dry to begin with, was now running (salivation) and he experienced some difficulty in swallowing. Exploration of the mouth showed a few characteristic vesicles on the tonsils with a little glandular enlargement under the lower jaw. Chlorate of potash internally and locally, was followed by improvement, but a few days later a small abscess formed at the left molar toe, which soon healed. The patient recovered without having been obliged to give up work.

The other cases were all very much the same, so I need not relate them in detail. My observations seem to me to justify the following conclusions:

1. Milk seems to be the vehicle of contagion, and it is evidently dangerous to take cow's milk in times of epidemic, even if the animals are apparently healthy unless it has been well boiled. In my first case, that of the infant, it will be noted that contamination took place before the animals displayed recognizable signs of disease.

2. Milk, however, is evidently not the only means of transmission, for in my second case the patient had not drunk any milk for a long time (French peasants as a rule right shy of milk). He no doubt contracted the disease by handling the cattle and eating his food with unwashed hands, the saliva and pus of sick animals being very contagious.

Symptoms.—The period of incubation would seem to be five or six days. There is a slight rise of temperature with dryness of the mouth followed by salivation and trilling disturbance of digestion. In the course of a few days we get aphthous stomatitis, which may undergo transformation into tonsillitis or aphthous stomatitis. Should the nature of the disease be overlooked or in the absence of adequate treatment, constitutional troubles may supervene a parathyphoid state, renal complications, sub-maxillary adenitis, &c.

It is at this stage that we meet with abscesses of the feet and hands which, however, in my own experience only occurred in one instance, though I have heard of graver cases in the neighbourhood.

Diagnosis.—Whenever foot and mouth disease is epidemic among cattle, we must be on the lookout for instances of contagion in man. In the earliest stage no diagnosis is possible, but as soon as aphthous stomatitis makes its appearance we have only to distinguish it from ulcerous stomatitis, thrush, syphilitic lesions, scurvy and diptheria.

In ulcerative stomatitis there is no true vesicle, merely a raising up of the epithelium by infiltrat

10. The subjacent tissues and the ulcer becomes visible on scraping away the epithelium. These lesions usually commence on the gums over the last molar teeth. Then, too, the lesions are much more extensive and deeper than in aphthous stomatitis (foot and mouth disease).

Thrush is recognized by features which are familiar to all of us—the little patches of milky-white, like flakes of coagulated milk, are quite different in appearance from the characteristic little ulcers covered with a thin layer of epithelium, met with in the disease under consideration.

There ought to be no difficulty in distinguishing it from syphilitic lesions which are well known to us and the same remark applies to mercurial stomatitis. In doubtful cases it may be advisable to treat the local lesions after instituting anti-syphilitic treatment. In the course of an epidemic no doubt can rise except in obviously syphilitic subjects, but the primary chancre and mucous patches hardly expose us to the risk of error. Apart from the constitutional symptoms of scurvy, the appearance of scorbatic gingivo-stomatitis is very characteristic, the wine-blue gum line, the ecchymoses and induration give their special stamp and the patient's aspect is quite different.

Diphtheria rarely limits itself to the buccal mucous membrane and the false membrane can readily be distinguished from the ulcerations met with in foot and mouth disease. In case of doubt bacteriological examination will settle the matter.

3. Acute tuberculosis of the pharynx or mouth is painful and is accompanied by intense dysphagia. The Leptotrix myosis is easily identified.

2. Should the manifestations be limited to the hands and feet diagnosis might be difficult in the absence of the characteristic stomatitis.

Foot and mouth disease in human beings does not seem to be a grave affection, but we must distinguish between its supervision in children and in adults. In the former it may give rise to serious constitutional disturbances. In my first case the infant's plight for twenty-four hours was most alarming. The gravity of the attack no doubt depends greatly upon the severity of the infection so that infants fed upon the unboiled milk of sick cows are liable to very serious manifestations.

Prophylaxis and Treatment.—Refuse all milk from a contaminated farm, and lest it should be imperfectly sterilised, do not advise boiling such milk for human consumption. An animal may be sickening for the disease without showing any outward and visible signs so that in presence of an epidemic they are all potentially dangerous. Farmers should be informed of the necessity for cleanliness in manipulating milk and for their own sake the sick animals should be carefully isolated from the healthy stock and the hands of attendants frequently washed in a 1 in 1,000 solution of oxycyanide of mercury. All manure to be burned or buried deeply after watering with a powerful antiseptic. In epidemic times we must beware of butter.

When foot and mouth disease occurs in human beings we must remember that it is apt to be much more severe in the young. Anti-diphtheritic serum by the mouth or by injection yields good results. The ulcers should be cauterised with chloride of zinc, 1 in 30, and the bowels kept open.
In adults, gargling with chlorate of potash or borax, frequent lavage of the mouth with diluted peroxide of hydrogen, either alone or associated with thymol.

There is one point to which I should like to call attention, viz., that the country doctor ought to have at any rate a nodding acquaintance with animal pathology in order that he may protect human beings from contagion. Foot and mouth disease by no means the only disease that is transmissible from animal to man; indeed, it seems to be one of the least disastrous.

THE MEDICAL HISTORY OF ABERDEEN. (a)
By SIR ALEXANDER OGSTON, K.C.V.O., M.D.,
Consulting Surgeon to the Aberdeen Royal Infirmary; Surgeon-in-Ordinary to H.M. the King in Scotland.

After leaving the physical conditions and general characteristics of the inhabitants of Aberdeen and district in the middle and latter part of the fifteenth century, Sir Alexander Ogston proceeded as follows:

Some time about the year 1481 there came to Aberdeen, in all probability by land, one who was destined to be the greatest benefactor, William Elphinstone. He had just been nominated to the bishopric of the diocese. It is difficult to reconcile the dates given by his biographers, but it must have been within a year or two of that time, and Elphinstone was a man approaching 60 years of age, when the churchmen, nobles, and citizens alike went in procession, with music, to meet him and do honour on the occasion to one whose advent they had greatly desired. We possess a portrait of him in King’s College in Old Aberdeen, which shows, I think, that he was a person of not more than medium height, with a sweet benevolent expression of face; his features indicating that he was a healthy man who had led a temperate life, and being unmarked by any lines that point, as do so many portraits of Scots of later period, to hardness or unscrupulousness, but showing thoughtfulness, earnestness, and goodness; altogether a beautiful character, in every respect coinciding with what we otherwise know of him. If one were to judge from the portrait alone, one would perhaps rather rank him among dreamers and visionaries, than among men of affairs.

Before he came to Aberdeen as its Bishop, Elphinstone had already occupied a post of high preferment in the diocese of Glasgow, and those were days which soon tested the characters of men, particularly of such as held high positions in the Church, both in England and Scotland. The ancient Church was being threatened, and the seeds of heresy were springing up in both countries. Hence the ecclesiastical dignitaries had found it expedient, in the beginning of the century, to burn the free-thinking James Ramsay at Perth, and only three years before Elphinstone was born the Bohemian convert Paul Craw was also burnt at the stake for his doctrines. Moreover, at the very date we speak of, the thirty “Lollards of Kyle” were already giving trouble, and a year or two later to be arranged before King James and Archbishop Blackadder, of Glasgow, on the charge of heresy, and probably they would have been burnt too had not the good-natured King turned the whole matter into a jest. It was indeed a thorny problem for the priesthood how to deal with such disturbing opinions, but the country doctor to the honour of Bishop Elphinstone that he sought what he believed to be the more excellent way to encounter heresy than by an auto da fe.

There are few beyond our walls who realise how magnificent a gift Elphinstone bestowed on Aberdeen and the North of Scotland when he founded our university, and there are few who appreciate the wisdom he displayed in his organisation. The bishop lived in an era of intellectual restlessness. From Italy and Germany, as we know, the “New Learning” was spreading, and altered ideas of morals and religion were being accepted in England and Scotland as the Middle Ages gave place to the Renaissance, but all that must have been familiar to Elphinstone, and he and the other prelates of the ancient Scottish Church much disquietude. The appropriate remedy was to be sought, so he believed, in a wider development of learning and the better instruction of the priesthood of his Church, while, if these objects were to be carried into effect, the establishment of a “Studium Generale,” or, in modern phrase, a university. Eighty years previously Bishop Wardlaw had been the means of founding such a place of study in St. Andrews, where it proved successful; but thirty-seven years after that Bishop Turnbull (or, according to Boece, Bishop Durnot) raised the college, where it had been less satisfactory. In the latter university Elphinstone himself had been a graduate in Arts as well as Rector, and he therefore possessed the knowledge requisite to avoid the errors which had caused it to be a comparative failure.

THE FOUNDATION OF KING’S COLLEGE.

As Lord Privy Seal to King James IV., he participated in his Sovereign’s most intimate councils, and there could hardly have been a ruler to whom the bishop might have applied with more hope of finding sympathy with his plans for the intellectual improvement of Aberdeen, and accordingly we find the King writing, in terms inspired doubtless by Elphinstone, to the Pope for his authority to found the university. Unfortunately, no traces of King James’s letter, or of any correspondence of Elphinstone with the Holy See, relating to the proposed creation of the university, now exist in the archives of the see; for they were likely have remained locked up, had that would have been instructive about the condition of Scotland. But what their terms were may be inferred from the wording of Alexander VI.’s Bull, which bears the date of February 4th, 1494. They are that Old Aberdeen was a centre of a district inhabited by ignorant and nearly savage men, many of whom were desirous of being taught, but were destitute of instructors, and were separated by dangerous and arduous ways from those who could impart knowledge, while it was nevertheless possessed of a good climate and fertile soil; and, finally, that, owing to unfavourable local conditions, the prelates and the people of the Church could hardly be carried on. Almost exactly a year later than this Bull, on February 5th, 1495, the Pope gave the first donation to the university of the revenues of the Hospital of St. Germanus in East Lothian, which had been attached to the diocese of St. Andrews, but had fallen into disuse, and these were to form an endowment for the maintenance of the three faculties most nearly connected with instruction in religion. Three weeks later still, armed with these documents, Elphinstone published his proclamation that the university was now established; and the date of this, February 25th,

(a) Abstract of Presidential Address delivered at the 32nd Annual Meeting of the British Medical Association, held in Aberdeen, July, 1914.
1496 is the real date of the birth of the University of Aberdeen.

At this point we pause to hold up to admiration the great wisdom of the bishop in respect to the study of medicine. Not a single university in the British Isles had, until this time, had an ordinary method to provide a faculty for them in a university. The bishop must have been personally acquainted with two of the Court physicians of his former master King James III. — namely, William Scheves, who flourished about 1472, and was acceptable to James on account of his knowledge of astrology; a reptile who schemed for the deposition of Bishop Graham of St. Andrews, successor to Kennedy, so effectually that he himself stepped into his shoes in 1478; and also his successor in the King's favour, Dr. Andrews, likewise an astrologer, in 1479, who, as it proved, lost his master both his life and kingdom by some pretense, and was the first to bring him against his brothers, the Earl of Mor, and Albany, the "father of chivalry." Whether or not Elphinstone was one of the small body of scholars who were acquainted with Greek, and knew or had heard of the writings of Hippocrates, Galen, and Avicenna, which were then beginning to be translated into Latin, or Continent, and to revive the science of medicine, but were unknown in Britain, we cannot pretend to say, though it seems probable enough. But his clear vision saw, what most of his contemporaries did not discern, that medicine, like other branches of knowledge, was likely to share the impetus received from the Greek Learning, and not only was a proviso introduced into the Bull founding the university that there should be a faculty "tam in Theologia ac iure Canonicorum et Civilibus, necnon Medicina et Artibus liberalibus quam quavis alia licta facultate," but he was so concerned about the interests of medicine that he procured from James, within a year of the inception of the university, a charter which, while repeating the Pope's injunctions about the teaching of theology, civil and canon law, medicine, and arts, gifted to God the Omnipotent, the most glorious Virgin Mary, all the Saints, the University, and to a graduate of medicine for 12s. yearly, thus supplying the deficiency in the Pope's endowment. From this charter, and the King's cooperation in founding the university, it came eventually to be called King's College, as Elphinstone had always wished it to be named.

Early Aberdeen Medical Worthies.

The medical seed which Elphinstone planted in his college did not at once spring up into full vegetation. It could not have been expected to do so under the conditions then prevailing. The English masters of medicine had not yet arisen; the scientific foundations on which modern medicine rests were not even begun to be laid. Linacre had not then introduced the works of the great Greek physicians into the profession in this country, and the great Harvey did not appear until a generation later. Physicians were barely more than herbalists, and surgeons than barbers. We have mentioned some of the positions attained to by those who added quackery and astrology to their healing functions; but for the honest practitioners knowledge, and their recompen
to small. I am indebted to our Public Librarian, Mr. G. M. Fraser, for information as to the status of doctors in Aberdeen about the time of Elphinstone.

In 1147 there was in the city an English physician of the name of John, but he does not appear to have found his practice very satisfactory, if one may judge from the solitary record of him which remains—that he sold his crofts beside the Stock-rud in the District. In 1478 there was the only Scotchman John de Ressivat, who was called Kileren, or for our shillings. The first "Physician," or Professor of Medicine, in the university was James Cuming, who before 1503 had been selected by Elphinstone and appointed to lecture on that subject. Elphinstone built him a house, as he did for the other professors, and we are told that it was one of his bishop's good offices that the city assisted in providing him with a more adequate salary than he received from King James's benefaction, for it is recorded that in the year 1501 the aldermen, bailiffs, council, and community consented to give him ten marks yearly, "ave and until the" promote him to a half of a rod's fishing in the Dee, free of entry money, he paying for it the usual rent, and engaging that he, his wife, children, and household, shall personally reside within the burgh, go and visit the sick, and show them his medicines, they paying for them, but the town is to pay nothing till Cuming has actually put it into practice.

From the evidence that Cuming was not a priest, but a regular medical graduate and a married man, with his patients to look after as well as his university duties. It does not detract from Elphinstone's merit in taking specific steps to ensure that medicine should have a due place in his university, that another Scotchman, "John Generale," entered into the profession than that in Aberdeen, should have had a similar authority to establish regular medical instruction conferred on it at its commencement. As early as 1413 St. Andrews had that right conceded to it in its Bull of Foundation; and possibly the licence for a Faculty of Medicine may have been a not unusual portion of the terms on which the Popes employed when bestowing their sanction on universities modelled on those of Paris and Bologna. Glasgow University, however, had no such privilege, only three faculties—Theology, Law and Arts—having been specified in its Bull.

The Foundation of Marischal College.

It may be interesting—and, at any rate, it enhances our appreciation of Elphinstone—to remark that when the second university of Aberdeen, that of Marischal College, was established a hundred years later, no provision was made in its Bull of Foundation. It was instituted under the same atmosphere of Calvinistic reform, and concerned itself more with religion and politics than with science. What we have said above regarding some of the many claims which Elphinstone has to be honoured is no more than a just tribute to the memory of a truly great man, whose marvellous wisdom and provision it is a duty to acknowledge; it is a tribute heartily paid by us all, whether we were alumni of King's or Marischal Universities, now happily fused into one. But here our brief sketch must close. Worthy to tell of the after-historians of the Aberdeen Universities and our medical school would demand greater eloquence than Nature has allotted to me, but a visit to the beautiful window in the Mitchell Hall of Marischal College will, I am sure, add an interest to your visit in this city, by calling to your minds a few of the names which are known wherever the English tongue is spoken, while there are others, and these not a few, whose memories are cherished by at least every well-informed inhabitant of this district, men whose deeds and works have been such that Scotland, and even
England, would be shorn of a portion of their glory were their names to be deleted from the rolls of fame of our common fatherland.

INTERNAL DERANGEMENTS OF THE KNEE.

BY ROBERT JONES, F.R.C.S.I. (Hon.), F.R.C.S.E.,
CH. LIVERPOOL
Lecturer on Orthopaedic Surgery, Liverpool University.

When your indefatigable and most persuasive secretary commanded me to deliver a short address before this distinguished and representative body of surgeons I was elated by the honour, but oppressed by the responsibility. Dr. Martin told me that all I had to do was to relate my experiences, both lengthy and authoritatively, upon any subject, and to show pictures. The said preceding I have, gentlemen, is that twenty years ago I could have been as dogmatic and authoritative as one wished—for at that time I was less conscious of the need of experience.

It is the subject of derangement of the knee joint because comparatively so little has been written about it in your own country, and this has always been a matter of great surprise to me, for your games, like our own, are rough, and we in England know to our cost that harm has been done from the outside, and very strenuous. I am credibly informed that the anatomy of their knee joints differs but little from our own, and I am forced to conclude either that their cartilages are more securely placed than ours or, which is most probable, that the condition is not so generally recognised as it should be. When I mention to you that I have explored the knee joint in search of mechanical derangement on considerably over 1,000 occasions, and that surgeons all over England are adding their experience and as I see are even allowing the anatomy of it; it seems perhaps appropriate that I should endeavour to place before you some practical points which may be helpful both in making clear the diagnosis and in simplifying the treatment.

The common derangement of the knee is injury to the internal semilunar cartilage. It occurs eight times as often as does injury to the external meniscus. The internal cartilage is more firmly fixed and in a position to give and take movement which requires the external, and in addition it bears a greater strain during the normal movements of the joints, often being thinned and frayed along its inner margin. The line of force is carried through the inner side of the knee in the normal relation of the femur to the tibia, while the abducted position of the foot, when exaggerated, produces outward rotation of the leg. The disproportion may be due to the shape of the internal anterior surface of the tibia, which is a direct strain on the semilunar, is greater than that of external rotation. It is well to remember how rarely the external cartilage is displaced, in view of the fact that displacement of the internal semilunar will at times give rise to symptoms on the outer side of the joint.

We must also remember that in nearly all cases the cartilage is displaced inwards, and on those rare occasions where the knee has been dislocated it is due to haemorrhage following a tear, a localised bruising of tissue or a buckling of cartilage, accompanied by effusion which gives rise to an irregular outline of the articular margin.

The most constant symptom of a displaced or fractured semilunar is a sudden inability to extend the knee. This generally comes on immediately after injury, but I have seen many cases where no story of large or long-continued displacement at the time of accident, although it has occurred at varying periods later. This may sometimes only appear so because of the difficulty an injured patient has in analysing his symptoms. Avoiding this fallacy, we may be assured that in an appreciable number of cases the locking is for the first time complained of long after the initial injury. This fact is important from its legal aspect. The most frequent cause of the displacement is fracture of the semilunar periodicular ligament while the knee is flexed and the tibia rotated outwards. In rare instances I have known a displacement to occur while the knee is fully extended. The force necessary to cause the derangement is only that which is sometimes transmitted to the limb accidentally, for the extension of the knee is painful over the site of displacement. I maintain that if an injured semilunar is rigidly treated after its initial displacement it is generally mild and it is best to belittle him—far much better chance than it does at any later period. If the reduction be immediate, efficient, and the limb be kept fully extended, there is every reason to hope for good union. The first displacement is not often accompanied by any synovial effusion, but if it is, however, must be absolute. All movements of the cartilage must be prevented until union of the torn structures is complete, and no lateral strain must be allowed until the lateral ligament, so often injured, has recovered its position. Sometimes reduction is of cutting a cartilage, but if no anastomosis be used I have always thought it wise to summon the assistance of the patient himself. I first fully flex his knee and rotate it inwards. I then tell him at the count of three to extend the limb as fully as possible by him by pressure from above. In this way he materially assists the surgeon and simplifies the reduction. I often in this way reduce displacements of several weeks' duration, and the reduction can usually be done in one attempt. If the displacement be slight, the patient usually knows definitely at once, and the surgeon, if wise, will abide by his verdict. If the patient tells you the cartilage is still out, he is generally right, and it is best to believe him. The knee should remain fully extended after reduction in all recent displacements. If the knee does not voluntarily remain completely extended, the displacement is not corrected. Such a joint, with a clear history of an injury, which has fully extended, the lateral ligament, should be treated by complete rest in full extension for four or five weeks. Instead of this the patient is usually allowed to get up and walk in a week or a fortnight. This is a grave mistake, and a mark of the highest ignorance in the management of the series of recurrences. The cartilages can only be retained in a fixed position when the limb is fully extended; they participate in all rotary and lateral movements of the joint; rest of the limb in the fully extended position is therefore indicated, and as long as the effusion lasts the patient should be recumbent. Prolonged effusion relaxes by elongation of all the protective structures of the joint; we should therefore aspirate if absorption be retarded. Elongation of the quadriceps is best observed in the patient in bed by the knee in the relaxed position, and I think the knee should be wrapped without flexing the joint. I am sorry to dwell so long upon the treatment of the initial lesion, but it is perhaps the most important point I have to suggest, and perhaps the most neglected. Unfortunately, many patients have been observed at the instigation of a hurried convalescence and the illusory fears of adhesions. They are only snares for the unwary. A little common sense should help us to realise that the best way to promote the healing of the cartilage is by rest, and not by occasional strain to promote its occasional strain. These arguments obviously do not avail us when dealing with recurring displacements.
When the patient is up we should guard his internal lateral ligament from the strain during walking by directing him to walk with his toe slightly turned in and his foot inverted. This is made easy by raising the heel of his boot a third of an inch on the inner side. This prevents the foot from shifting from the inner to the outer lateral ligament, just as it would do in an early case of knock-knee.

It is more common to see the case when the acute symptoms are over or when several recurrences have taken place, and the patient himself, a history, which is usually definite enough. First we hear of an injury—it may be severe or very slight—it usually refers to abduction of the foot, to flexion and external rotation of the tibia. Locking of the knee mark will usually occur, and if the patient is questioned he says he has been unable to move it or he has been unable to straighten it, and when locking has not occurred, a giving way or slipping is referred to. The story of a reduction makes the diagnosis complete. If the knee be examined a few weeks after the accident, the effusion will have done, but there is often pain on pressure over the internal lateral ligament and above the tibial margin over the anterior horn of the semilunar. Pain is frequently felt in front of the patella, and this is to be distinguished from the knee. At first still later stage recurrences and fresh effusions may have occurred, accompanied by locking of the joint, the pain on each occasion being capable of definite localisation. Locking is the most definite and the most frequent symptom of recurrence. All signs of doubt must remain. On exploring the knee one frequently finds a fractured or displaced semilunar where there has been no clear history of locking, but the discovery is made, if not with surprise, at least with a certain amount of satisfaction. One is only prepared to admit to a something yielding on the inner side of the knee which gives him a sense of insecurity. This may involve only a momentary inconvenience, or it may occasionally be accompanied by synovial thickening of the lining membrane. The only safe way is to be prepared to admit to it, merely giving him a sense of insecurity. However these symptoms may differ, the one constant fact should remain, namely, that the patient is always definitely clear that the sensation does not change from the accident. The various displacements are often said to be accompanied by a click.

There is no time to deal with the exceptional case which makes the story of the knee joint so fascinating. It is often too liable to be exaggerated by itself, and to be misused without an operation. Among such abnormal cases I have found the external cartilage on the inner side of the knee, and I have found the fractured end of an internal cartilage lying on the outer side just internal to the tibial tubercle. The two pieces of bone so split up that different segments of the same cartilage would become displaced at separate times, giving rise to distinctive symptoms. Frequently I have found two separate lesions, either of which would account for the symptoms, and unless both were rectified the operation might have failed. Sometimes fringes and lipoma and pedunculated semi-detached bodies have been present when I have expected a displaced cartilage, and I have sometimes even had to close my wounds. It may be that he feels something slipping in and out, merely giving him a sense of insecurity. Therefore these symptoms may differ, the one constant fact should remain, namely, that the patient is always definitely clear that the sensation does not change from the accident. The various displacements are often said to be accompanied by a click.

Although these surprises take place, the diagnosis of a dislocation is simply made. In combination with the matter in most cases. It is liable to be confused with certain pathological conditions, of which the most common are synovial fringes, loose bodies, lipoma, and extra-auricular osteoma.

The pain is greatest in their primary onset in synovial fringes; the pain is quite local and is not situated definitely in the internal lateral ligament. Locking in the joint is common, and effusion almost invariably follows each slipping. There is usually in the recurrent case a thickening on each side of the ligament of the patella due to hypertrophy of the post-patellar pad of fat. One may expect to find synovial fringes attached to a post-patellar pad in cases of recurrent slips. The synovial plexus of the knee where the pad is found thickened and where occasional twinges occur in front of the joint.

Loose bodies lock the knee sometimes, but usually only for a brief moment, and the symptoms, although sharp, are not acute. They can be manipulated, because, unless pedunculated, they can be isolated in different parts of the joint, although they usually have a favourite resting place. They can generally be demonstrated by radiating from an lipoma to lock the knee, but the symptoms they produce are rarely acute. They are often accompanied by painless effusions, and can generally be felt in the122714.

An ostoma can usually be detected by careful examination. It can be felt and radiographed. It is the means of locking a joint when a muscle or tendon slips over it, but the locking is never accompanied by effusion.

There is a type of knee which clicks on full extension, and whenever you place your finger the clicking seems immediately under it. This is sometimes due to a nodular condition of the anterior portion of the semilunar cartilage, which is driven into the joint. It is very curious to watch as the recurrence occurs. This condition is sometimes followed by acute symptoms, and I encourage it in all recurrent cases where a strenuous athletic life is a means of abnormal necessity. Operation is a positive necessity in the case of men who walk or run with moving machinery or stand in positions where a yielding knee may mean disaster. I have operated upon patients from twelve to sixty years; age, therefore, is no contraindication in such cases. They have usually operated after trying everything, with the knee flexed to right angles, so that it need not be further flexed during the operation. I have a very real dread of accidental infection of a knee joint, for it may mean the loss of a limb. Further, I consider a knee which has been the seat of one or several attacks susceptible to infection, and am therefore careful not to operate during the presence of effusion nor to move it during operation for fear of the ingress of air or dirt. The most convenient way is to have the limb hanging in flexion over the operating table. Some thicknesses of gauze, squeezed out of a solution of biniode of mercury, is wrapped round the joint, and the incision is made through the gauze. The cut edges of the skin are then fixed into the wound. In this position it is not necessary, excepting in very stout people, to make the incision longer than an inch and a half. The incision I now employ is near-transverse, commencing just behind the ligament of the patella, and traversing slightly above the tibial border, taking care to spare the internal lateral ligament from injury. I am often consulted by patients whose knees have remained weak after operation. In such cases it often appears that the surgeon has carried his incision a little back, and has thus damaged the lateral ligament. Pressure over the ligament often causes pain, the calcaneal in the ligament being stretched and tender—a condition which only requires complete rest and strain for a complete recovery to follow. Through the small incision an excellent view can be obtained of the joint, the interior of which is then inspected with the aid of retractors. The finder should never enter the joint. Neither the surgeon nor the assistant should touch the wound except with sterile instruments; the sutures for the capsule should be manipulated with forceps, the edges of the capsule being secured by a blanket stitch. The cartilage may be found in almost any conceivable position. The lines of fracture of the ligament must be nipped up and it may be detached anteriorly; it
may be turned inwards like a bucket handle with its convexity inwards. It may be nodular; the posterior part may be in front; the anterior portion may be loose and nodular; it may be attached at its extremiti-
ties and free along the whole part of its outer border; it may be firmly fixed with its inner border frayed and the other part in line. If the wound is over so or found quite loose as a separate body; it may look quite normal, but its moorings found loose, or the posterior part may be split, which can only be dis-
covered by detaching the anterior portion and draw-
ing the talus through the free part of the joint. An examination should be gentle, and it is made easier by the use of a small blunt hook. It is only necessary to remove the loose portion of cartilage if the re-
mainder be firmly attached. If it be decided not to remove, the cartilage, can be split, and should be taken to make the section without drawing upon the stump, otherwise it will be loosened and give rise to symp-
toms of recurrence. The capsule should not be closed until a search has been made for fringes, tabs, or other foreign matter. I always apply a tourniquet, never tie a vessel nor drain the wound. Effusion, if it occurs, is usually very trivial if the operation has been done gently. As no structures of any importance to the stability of the joint have been se-
ven, the knee is defined in ten to fourteen days, the joint being protected for another week. Loose bodies of whatever type should be removed. An endeavour should first be made to localise and fix them. This should be done immediately before an anter-
ior incision, when the patient's assistance can be ob-
tained if necessary. The patient's hands should be sterilised and he should wear a mask and rubber gloves, and when found the fixed body should be placed in the keeping of a reliable assistant, and the knee should be kept extended during this operation. These loose bodies are often found in connection with rheumatoid arthritis, and should be removed whenever practicable. This may involve splitting the patella longitudinally to obtain a view of the interior of the joint. Loose bodies are frequently found at the back of the joint, and obstruct flexion and sometimes extension. They cannot be effec-
tively removed by an anterior incision, and, after they have been removed, the patient's assistance can be ob-
tained if necessary. The narrow communication between the anterior and post portions of the joint prevents them from travelling if they should prove of any size, therefore their removal is not difficult. An incision is made through the patellar cartilage, to obtain a view of the inner part of the joint, and the knee is then drawn outwards and to the outer side, and usually the loose bodies can be felt through the capsule. This route has also been described by my friends Brackett and Osgood. I have many times operated upon joints that became locked in flexion by the action of muscles or tendons over exostoses around the knee. The slice shows such a case. The patient, a good athlete, was frequently pulled up when running with a pain at the back of his joint, which I ascribed to an external semilunar. The knee shows a case of exostoses, which obstructed the vastus. When removed it was found to be surrounded by a bursa containing fibrous masses. This is usually a sequel of several operations, such cases as up which I have operated. The patient usually gives the history of a slipping at the back of the knee joint, which takes place only during unusual or active exercises. The knee sometimes completely locks and the derangement is immediately difficult to reduce, the symptoms usually not being severe, merely a sense of discomfort and slight slipping. The patient falls, gets up again and feels the back of his knees and then goes on with his game. Sometimes it is the big toe which is cramped, the patient feels the hamstrings, and in one instance I removed a peduncu-
lar exostosis, which frequently became enmeshed with the inner head of the gastrocnemius. Here you see an osteoma, which ceased to trouble us at all after the knee was fixed. I have operated on occasions to obstruct the sartorius. The next plate shows a flattened osteoma, which gave rise to symptoms suggestive of an injured semilunar, really due to its contact with the sartorius and semitendi-
 nosus, and the osteoma shown in the next slide caused the patient no inconvenience until it was removed. More rarely derangements may arise from sharp exostoses over the adductor tubercle, as shown on the following slide.

The diagnosis of such cases is easily made. They can be felt by the finger and demonstrated by the X-ray.

These cases are only a few of a large number which prove the part osteoma may take in disarranging the mechanism of the knee. Osteomata are so often found causing no symptoms that their evil conduct may sometimes be overlooked.

There are two conditions to which I would make a brief reference, as they give rise to very considerable disability: I allude to rupture of the crucial liga-

tment and fractures of the tibial spines. The dia-
gnosis of ruptured crucials is simple if we remember their function.

The anterior crucial ligament is tense when the knee is fully extended, and prevents the tibia from being displaced forwards on the femur. The posterior crucial ligament is tense in complete flexion, and prevents the tibia from being displaced backwards on the femur.

Both ligaments check inward rotation of the tibia. Hence, if after an injury of the knee the tibia can be displaced backwards or forwards or rotated inwards or outwards in the extended position, an injury of one or both crucial ligaments may be assumed.

If in the extended position the tibia cannot be dis-
placed forward, it may be assumed that the anterior crucial ligament is not torn.

If the tibia cannot be displaced backwards when the knee is flexed, the posterior crucial ligament is not ruptured.

The diagnosis, therefore, of ruptured crucials is not difficult, only in the instance of those cases of abnormal length due to elongation or destruction of the ligaments associated with long continued flexion into the joint or with changes associated with Charcot's disease. A large experience of the dislocation of joints gives me the authority to state that if injuries resulting in ruptured crucials be treated by rest to the joint for several weeks an excellent recovery will usually re-
sult. It is therefore wise to attempt their restora-
tion by operative means.

Ruptured crucials of the tibial spines, of which I have seen many cases, may or may not be associ-
ated with rupture of the crucials. The most constant sign of this fracture is an obstruction to full extension. The block feels like a definite bony ob-
struction, and is quite different from the blocking, which occurs when a dislocated semilunar or a synovial fringe is nipped. If the spine be fractured and the knee is prevented from full extension, then with the knee flexed over the table end the patella should be split longitudinally, the incision being carried a suffi-
cient length to allow the split portions to be drawn laterally over the condyles. The patellar pad should then be removed, together with the spine and any fibrous masses that obstruct. A good deal of blocking should be present an operation is not needed, and the knee should be treated by rest and fixation in full extension.

Mr. President, ladies and gentlemen, I feel that I have placed these elusive injuries of the knee before you in so condensed and hurried a manner as to rob a fascinating subject of its charm. If this be so, I claim your kind indulgence. The lesions are probably much more common than we are usually led to believe, and suggest, but if by good fortune the clinical suggestions I have offered you should prove of practical use, I shall feel more than ever grateful for this privilege of addressing you.

Dr. JAMES NEIL, M.D., formerly Medical Superin-
tendent of the Warrneford Mental Hospital, Oxford, left estate of the gross value of £6,000.
OPERATING THEATRES.

ROYAL FREE HOSPITAL.

TUBERCULOUS PERITONITIS.—Mr. Wilmott Evans operated on a child, aged 12, who had been admitted for distension of the abdomen. The girl had been well until 8 months before, when she had suffered from irregular attacks of diarrhoea, accompanied by some abdominal pain. She had wasted, but after a time the abdomen began to increase in size, though the diarrhoea had ceased. On admission, she was seen to be small for her age, badly nourished, and the abdomen was much swollen. On percussion, there was dullness in the flanks and above the pubes nearly to the umbilicus, but the remainder of the abdomen was resonant. There was no evidence of any pulmonary tuberculosis. A diagnosis of tuberculous peritonitis was made. She was kept under observation, and the distension of the abdomen slowly increased, causing her some discomfort. It was determined to operate.

The abdomen was opened by a median incision about two inches below the umbilicus. When the peritoneum was opened it was seen to be thickly studded with tubercle and the small intestine which presented in the wound was similarly affected. About a pint and a half of fluid was evacuated; it was clear, but contained straw-coloured lymph. As the tubercle fluid was coming away the peritoneum was sewn up with silk, the fascia drawn together, and the skin sutured. The wound was dressed with aseptic gauze, and the patient returned to bed.

Mr. Evans said that tuberculous peritonitis might arise in two ways: in one form the inflammation spreads from a tuberculous ulcer of the small intestine through the intestinal wall; usually the involved peritoneum is another pectoralis, and the general peritoneal cavity is not affected; but it may happen that some leakage occurs so that tubercle bacilli gain access to the general peritoneal cavity, giving rise to tuberculous peritonitis. True perforation of a tuberculous ulcer of the intestine very rarely occurs. Secondly, and this he considered is the more common way, tuberculous peritonitis may be set up by the bursting of a tuberculous mesenteric gland. When this happens tubercle bacilli are widely scattered all over the peritoneum, and immeasurable tubercles form. The surgical treatment of this condition, he pointed out, arose from the successful result of opening the abdomen in a case of tuberculous peritonitis. A case of laparotomy and a laparotomy was a case, where the diagnosis was uncertain, but finding that tuberculous peritonitis was present he did nothing more, simply closing the abdomen. To his surprise the patient recovered, and this case is noted in an individual case. Mr. Evans remarked, whether a laparotomy will do any good, but a successful result follows in so many cases that it is always advisable to do it, unless some distinct contra-indication be present. It is sufficient to make a small opening into the peritoneal cavity to evacuate any fluid that freely comes away, and then to close the abdomen. It is important not to employ drainage; it does no good, and may lead to peritoneal infection. In a few cases, if the operation is carried out and a laparotomy is made, one or two months later may succeed. In cases in which it appears to be desirable, laparotomy may be performed under local anesthesia. While there can be no doubt as to the success of laparotomy in cases of tuberculous peritonitis, there is much doubt as to the mechanism by which the improvement is brought about. Possibly the operation causes a local leucocytosis which leads to obstruction of the tubercle bacilli, possibly that the circulation of the peritoneal cavity and its contents may be disturbed so that absorption takes place. It must be admitted that these explanations are hardly satisfactory.

The medical history of the case was that additional effusion occurred soon after the operation, but this was soon absorbed, and the patient was able to leave the hospital about a month later in a greatly improved condition.

SPECIAL REPORTS.

THE EIGHTY-SECOND ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT ABERDEEN, 1914.

(By Our Special Representative.)

THIRD ARTICLE.

THE WORK OF THE SECTIONS.

SECTION OF ANATOMY AND PHYSIOLOGY.

A great many papers were read in this section dealing with the development and physiology of the heart. Dr. D. Ley Macfarlane (Glasgow) reported on the bird's and the reptilian heart. Dr. Strickland Goodall (London) read a communication on "Some Instrumental Variations in the Human Electrocardiogram." Dr. E. S. Edie read a paper on some experimental work on the action of enzymes.

SECTION OF DERMATOLOGY AND SYphilis.

Dr. Norman Walker (Edinburgh) opened a discussion on the first day on "The Need for more Method in the Conflict with Lupus and Ringworm," followed by Dr. Alfred Eddowes, President, Drs. Goldwin Telford, PH. D., William J. Winfield, Hume, Winibred Williams, Green and Menachen. On the second day a joint meeting was held with the Section of Naval and Military Medicine and Surgery, when a discussion took place on "The Modern Treatment of Syphilis," in which Mr. J. H. Roseiough, Colonel T. W. Gibbard, K.H.S., Major L. W. Harrison, and Dr. J. C. McWalter, among others, took part. On the Friday various interesting papers were read.

SECTION OF DISEASES OF CHILDREN, INCLUDING ORTHOPEDICS.

On the first day Mr. T. H. Openshaw introduced a discussion on "Congenital Dislocation of the Hip." The view was put forward that treatment should be begun as soon as the diagnosis is made. A discussion on the thymus gland in its clinical aspects was opened by Dr. Archibald Garrod on the Thursday. Among the interesting papers read on the last day were "Lyme Salts in Children's Diseases," by Dr. J. C. McWalter (Dublin); and two by Mr. Paul B. Roth on the treatment of torticollis and lateral curvature of the spine.

SECTION OF ELECTRO-THERAPEUTICS AND RADIOLOGY.

Professor Leduc of Nantes, whose work on ionisation is so well known, gave an account of his experiments regarding the galvanisation of the brain. Some interesting papers were read on the effects of high frequency currents, and the comparative value of X-rays and radium in the treatment of malignant growths. On the Friday a joint discussion was held with the foregoing section on "The Diagnosis of Chronic Pulmonary Tuberculosis in Infancy and Childhood," in which Drs. D. B. Lees, Clive Riviere, and Ironside Bruce, among others, took part.

SECTION OF GYNECOLOGY AND OBSTETRICS.

A discussion took place on the Wednesday on the treatment of fibromyomata, opened by Dr. Archibald Donald (Manchester), followed by Professor Gauss (Freiburg). On the next morning Dr. Henry Jellett (Dublin) introduced the subject of "The Management of Pregnancy and Labour in Contracted Pelvis." The last day was occupied by the reading of papers and a "Drug Treatment of Dysmenorrhoea," by Dr. J. C. McWalter; "Acidosis and the Nitrogen Particles in Pregnancy," by Dr. H. Leith Murray, and one on contractile pelvis, by Dr. D. Shannon.

SECTION OF LARYNGOLOGY, RHINOLOGY, AND ENT.

A discussion took place on the first day on "The Treatment of Inoperable Growths of the Nose and Throat," in which Mr. W. D. Hamner, and Drs. W. Hill and J. M. Macintyre, among others, took part. On the following Thursday Dr. A. A. Gray introduced the subject of otosclerosis and various cases submitted during the previous week, and on the following morning Sir William Milligan (Manchester) demonstrated a new form of extending broncho-esophagoscope.
MEDICAL SOCIETY.

Considerable interest was shown, naturally, in the proceedings of this section, which was presided over by Dr. J. Gordon (Aberdeen). Dr. A. K. Chalmers, M.O., H., Glasgow, opened a discussion on “The Relief of Pain in the Trenches,” in the absence of Dr. G. Robertson (Edinburgh). He pleaded for freer opportunities for the diagnosis of these diseases, and he thought that the Government should assist local authorities, financially in the matter of equipment. Dr. H. H. Mills (Kensington) expressed his belief that the desirability of imparting instruction on sex hygiene to scholars. On the Thursday Sir John Collie opened a discussion on “A State Medical Service,” and a symposium. He said that the condition under which the medical work was carried on under the panel system was, in many cases, not medical practice, but commercialism of the worst type. Dr. H. H. Mills (Kensington) thought that the suggestion of mapping the military precision into brigades and battalions each with its medical officer was against our national characteristics. A separate discussion took place on “Medical Certification following Wound injury in regard to the University and Ministry, which was opened by Mr. C. Sandeman, K.C., and followed by Drs. A. C. Farquharson (Cork), and J. C. McVail (Glasgow). On the last day Dr. Leslie Mackenzie (Edinburgh) opened a discussion on “The Training of the State towards the Early Environment of the Child,” followed by Drs. J. Caravel and T. Dewar.

SECTION OF MEDICINE.

Dr. Harry Campbell (London) introduced a discussion on “Headache,” followed by Dr. C. O. Harker and others. Dr. J. S. McIndoe (Glascow) read a paper on “Splenection in relation to the Treatment of Anaemia.” On the following day Dr. Rist (Paris) opened a discussion on “Thoracic Pneumothorax and Thoracic Evisceration.” After the combined discussion already mentioned as taking place on the last morning with the Section of Diseases of Children, various papers were read, among which may be mentioned that by Dr. D. D. Brown (Harro- gate) on rheumatoid arthritis and that by Dr. W. Haig (Glasgow) on the rapid relief of acute hantigo by manipulation and active movement.

SECTION OF NAVAL AND MILITARY MEDICINE AND SURGERY.

On the first day a discussion was opened on the treatment of wounded in naval warfare by Fleet-Surgeon D. Walter Hewitt, R.N. The subject of “Gangrene in War” was introduced by Captain C. M. Page, R.A.M.C. (S.R.), while the treatment of venereal diseases, and soldiers in civil life was discussed by Lieut.-Col. E. M. Wilson, C.B., C.M.G., D.S.O., R.A.M.C. (R.P.). On the next day the combined discussion took place on syphilis as mentioned above, followed by one on “Common Allments of Camp” introduced by Captain C. Johnson, M.B., R.A.M.C. (T.F.). Staff-Surgeon G. M. Levick, R.N., gave an interesting illustrated lecture on the experiences of the Northern Party of Captain Scott’s expedition; Section of Naval and Military Medicine and Psychologic Medicine. A discussion was opened by Dr. F. W. Mott, F.R.S., on “Diagnosis and Treatment of Parienymastyhous Syphilis.” On the next day Dr. C. G. Jung (Zurich) introduced the subject of the psychopathology of psycho-pathology. The last day was given over to papers which included one on “Anger in its Medico-Psychological Aspect,” by Dr. J. B. Hyclop, and one on “The Psychic Factor in Insomnia,” by Dr. Critchon Miller.

SECTION OF OPHTHALMIC.

Mr. E. F. Maddox (Bournemouth) opened a discussion on the choice of a cataract operation. The next day a discussion on a case of facial paralysis with paralysis of light reflex and near vision, introduced by Mr. J. Herbert Parsons (London). Dr. Maitland Ramsay (Glasgow) opened a discussion on the last morning on the teaching of opthalmology to medical students.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

The President, Dr. W. S. Lazarus-Barlow (London) opened a discussion on “The Action of Radiation on Cells and Fluids.” Dr. Carl Brown introduced the question of the bio-chemistry of immunity reactions, followed by Drs. H. K. H. Alexander and Mr. H. Mackenzie Wallace. On the next day a joint discussion took place with the Section of Pharmacology on “The Pathology of Heart Function,” opened by Dr. J. F. E. Leveson (London), followed by Dr. T. G. Barr and Dr. G. M. C. Glaxton. On the Friday Dr. W. J. C. M. H. D. B. Macrae introduced the subject of “The Importance of Variability among Bacteria and Its Bearing on Diagnosis.”

SECTION OF PHARMACOLOGY, THERAPEUTICS AND DIETETICS.

Professor J. T. Cash (Aberdeen), who presided, advocated the use of the metric system in prescribing, with a view of bringing laboratory and clinical work into closer relation. Dr. J. M. Fortescue Brickdale (Bristol) opened a discussion on “Recent Advances in the Relationship between Chemical Constitution and Pharmacological Activity.” The last day was occupied with a discussion on the pharmacology and therapeutics of the animal extracts exclusive of thyroid extract, in which Prof. Noel Paton and Dr. O. F. Greenbaum took part. Dr. Chowry Muthiu (Wales) read a paper on diet in the treatment of pulmonary tuberculosis.

SECTION OF STATE MEDICINE AND MEDICAL REFORM.

Professor Matthew Hay (Aberdeen), the President, in his introductory remarks, thought that our changed attitude with regard to the criminal betokened a great advance in medical jurisprudence. Sir Victor Horsley then opened a discussion on death certification, and Dr. F. H. Bruce (Dundee), Dr. J. C. Dunboy (Register House, Edinburgh), Dr. F. E. Wynne (Wigan), and others, had spoken, the following resolution was moved and adopted—“That the British Medical Association reaffirms its opinion that extensive reforms in the administration of national statistics of life and death are urgently needed, especially the immediate institution of a confidential system of death certification, and the Association therefore calls on the Government to introduce legislation to effect this essential change in the public health service.” Dr. J. C. McWalter (Dublin) read a paper on “Legal Investigation of Cause of Death, with Suggestions for Reform.” Numerous other papers on medicolegal problems health subjects occupied the rest of the programme.

SECTION OF SURGERY.

In spite of the fact that this section was overshadowed by the Clinical Congress of Surgeons of North America, held in London at the same time, much good work was done. A discussion took place on the first day on “Pharmacology and Treatment of Carcinoma of the Tongue,” opened by Mr. W. G. Spencer (London). Professor J. K. Jamieson and Mr. J. F. Dobson (Leeds) read a paper on the lymphatics of the tongue. On the next day Mr. Robert Jones (Liverpool) opened a discussion on the surgical treatment of arthritic deformities. On the Friday Mr. H. M. W. Gray (Aberdeen) introduced the subject of “Anoel-Association, or the Evolution of the Shockless Operation.” Many valuable papers were read in this section, which space forbids us to enumerate.

SECTION OF TROPICAL MEDICINE.

Fleet-Surgeon P. W. Bassett Smith, C.B., R.N., opened a discussion on Kala-azar and allied conditions, followed by Professor V. Gabbi (Rome), Dr. P. H. Bahr (Cevoni), and others, Dr. A. A. F. MacCanon (Egypt) read a note on a new antimalarial. On the Thursday, Col. King, C.I.E., I.M.S., opened a discussion on “The Education and Position of the Sanitarian in the Tropics.” The last day was occupied by the reading of papers and by a discussion on the treatment of syphilis and the surgical treatment of collits and post-dysenteric conditions.

(The topic continued.)
ROYAL COMMISSION ON VENEREAL DISEASES.

Mr. Pugin Meldon, Senior Surgeon at the Westmorland Infirmary, Appleby, gave evidence before the Commission as the representative of the Joint Committee appointed by the Royal College of Physicians of Ireland, the Apothecaries' Hall, Ireland, the School of Medicine at Trinity College, Dublin, and the National University of Ireland, with a view to laying stress on the point that the difficulty in dealing with venereal disease arose from the social stigma attaching to those suffering from it. This stigma was certainly a hindrance to early diagnosis and treatment, and therefore desirable that the treatment of the general class of venereal disease patients should be expedited. The treatment of the treatment of the general class of venereal disease patients special dispensaries and hospitals or special laboratories for diagnosis. As regards diagnosis, it was essential that clinical methods should be supplemented by the aid of the pathological laboratory, and arrangements should be made for the free diagnosis of venereal disease at the laboratories in the Pathological Departments of the Universities and Medical schools.

With regard to treatment, the Committee were of opinion that one cause which operated very extensively in deterring people from obtaining proper treatment was the penalisation of venereal disease. Expenses incurred in seeking a physician or other dismissing from their employment persons who were found to be suffering from these diseases, or refusing them leave for the purpose of treatment. The result was that these persons either endeavoured to treat themselves on the non-penalising method of course or sought a physician when the disease was far enough advanced that they were unable to do their work. So long as this penalisation persisted, it was impossible seriously to suggest any scheme of notification, and therefore desirable that some method of penalisation be given. Similar consideration led the Committee to suggest that the Insurance Act should be amended so as to make it impossible to withhold sick pay and disablemen for venereal disease.

Mr. Macleod Yearns, Senior Surgeon to the Royal Ear Hospital, stated that in his opinion syphilis and its concomitants was as severe amongst children of the poor as it was when he started practice as an auricular surgeon twenty-one years ago. He had found that amongst children there were far more cases of manifest congenital syphilis among the poor than among the better class. He attributed to the fact that in the latter the disease was recognised earlier and therefore treated earlier. Among the poorer syphilis very often went untreated, and this was especially the case with children. As showing the number of children with congenital syphilic deafness appearing after birth with sufficient severity to necessitate special education, he referred to records he had kept in connection with work at special deaf schools. Of the 84 children (42 boys and 42 girls) examined during a period of seven years, 61, or 72·7 per cent., were deaf from congenital syphilis. The frequency of defects in excess of the male, the relative percentages being: boys 40·4, girls 9·6.

Dr. James Galloway, Senior Physician to Charing Cross Hospital, stated that recent experience gained in dealing with venereal diseases in Army and Navy greatly encouraged the expectation that these diseases might, if favourable conditions were obtained, be prevented and their evil consequences diminished in the general population. He did not think that compulsory measures of believing registration and treatment were likely to lead to satisfactory results. In dealing with the general community, it was necessary that all efforts to cure and prevent the disease in any given position, and adhesions in cases, should be strictly voluntary, with the willing consent of the sufferers and by the sympathetic co-operation of the rest of the community. Social stigmata should so far as possible be removed from those under treatment. It should be strongly impressed upon the public that large numbers of persons suffered from venereal disease through no fault of their own. All hospitals willing to undertake the treatment of venereal diseases in their early or acute stages should be encouraged to do so. If this were done facilities would immediately be at hand for the greater number of patients. It was especially desirable that hospitals with medical schools should undertake the treatment of these diseases in a general scheme of dealing with these matters that would meet the community. Opportunity would thus be provided for the instruction of medical students in the recognition and treatment of venereal diseases in a way which had been impossible in the past. He also thought that the cost involved in the treatment of these diseases on a large scale would be considerable, and as the proper treatment and eradication of the diseases was a matter affecting the general health of the whole community, it was proper that the expense should be met by local authorities or by the State.

REPORT OF THE HOMES FOR INEBRIATES ASSOCIATION.

(a)

The report of the Medical Superintendent of the Dalrymple House contains a good deal of interesting information concerning the treatment of sufferers from alcoholism and drug habits. 57 patients were admitted during the year under review, 42 under the "private patients," and 21 under the Inebriates Act. The difficulty in treating the former class is due to its optimism. Most people object to signing away their liberty, and all the same are too eager for recovery and precipitation of their own judgment of the complete rehabilitation of their self-control. The aim of the Medical Superintendent is to cure the cases with the least discomfort to themselves. Alcoholism, as a past, is treated as 'do or die,' which figure certainly shows a proportion of success that is most encouraging to those of us who are daily brought face to face with the awful results of overindulgence in alcohol, and similar suicidal habits.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Aug. 2nd, 1914.

At the Gesellschaft für Psychiatrische und Nervenkrankheiten, Dr. Kramer related a case resembling Paralysis Agitans.

The patient was a man, aged 58, who had always been in good health. Two years ago, he became deaf. The disease began ten years ago, and for the last five years he had been incapacitated from work. Gradually a slowness and difficulty had come on for all movements of the body, the voice became soft, and speech slow. He could not perform even the simplest acts. Occasionally he attempted to raise himself from a stooping position and had a tendency to fall backwards. All symptoms had gradually become worse. Objectively the remarkable thing was that the entire body was drawn forward, the mask-like expression of the features, slowness and difficulty of performing all bodily movements. There was, moreover, a prolonged interval between the closure of the eyelids, a tendency to tremor in any given position, and ataxia; also a tendency to ataxia and not infrequently ataxia. These symptoms corresponded to paralysis agitans, but there was no tremor nor rigidity of the muscles; it was only when the head was being

moved passively that there was any resistance. The pupils reacted to light. The Wassermann reaction of the blood was positive. The movements of the eyes were also slow, and there was slight nystagmus. When the eyes were moved slowly he got a wider range of movement than when they were moved rapidly. The movements of the mouth were more extended than the voluntary ones, but they were still below the normal. There was no amблиопия. The remainder of the nerve functions, also the electrical excitability, were normal; the mental condition was also normal. The temperature was 100 F. Practically, the case was one either of atypical paralysis agitans or a localised affection due to arteriosclerosis or syphilis that had a localisation corresponding to that of paralysis agitans. In any case the presence of rigidity was remarkable after so many years. The case showed that the disturbance of movement of paralysis agitans was an independent symptom, and had nothing to do with stiffness of the muscles. Mr. Maza said he had had a similar case in which all movements of the eyes were performed slowly. That case was one of Friedrich's disease probably. The same symptom had been observed by Westphal in a case of pseudo-sclerosis.

In a case of caloric irritation of the vestibuher the following curious condition was observed: Some seconds after syringing out with from one to two litres of water at a temperature of 20° C, with the head held erect was so far that the patient could not move the eyes to the left beyond the middle line, whilst movements to the right were performed with the usual pathologico sluggishness. If the ear was washed at a temperature of 42° there was a momentary disturbance of movement towards the side that was being syringed. These disturbances were greater when cool water was being made use of for the syringing.

At the Verein für Innere Medizin, Dr. Falk spoke on the Treatment of Tetanus Neonatorum. During a period of four months the speaker had seen three cases of the disease at the Kinderkrankenhaus. He had treated all three with injections of magnesium sulphate (8 to 25 per cent.). The paralyzing action he combated by calcium chloride. All children recovered. The magnesium had the effect of controlling the spasms.

Dr. Finkelstein said that the duration of the disease was not shortened, but the great advantage gained was saving of the patients from attacks of spasm during which children died often.

Dr. Czerny asked whether tetanus neonatorum was an infective disease.

Dr. Falk, in reply, said that the magnesium sulphate must be given in full doses, but one had to be careful not to cause paralysis, if given too late the convulsions were not prevented.

At the Verein für Innere Medizin, Dr. Bieling gave a communication on the Action of Extracts of the Endocervical Glands on the Tissue Changes of Rachitic Infant.

Various glands with an internal secretion, he said, had an effect on the growth of bone. In the first rank, the anterior lobe of the hypophysis, the parathyroid, the sexual glands, and in young animals the thymus. He had also seen that of phosphorus substances by injecting them into rachitic children. When he injected every day 0.5 c.c.m. of a 10 per cent. extract of the parathyroid of the sheep both lime and phosphorus were retained, whilst retention was much lowered when the injections were suspended. Growth was influenced by injection of the thymus extract of the calf. When extract of the anterior lobe of the hypophysis was given there was diminished retention of lime, but injection of phosphorus substances by injecting them into the children did not have this effect. The thymus extract would appear extract of the parathyroid was of great importance as regarded the growth of bone.

Dr. Oswald Meyer said he had seen recovery take place in a case of spasmophillia after the use of parathyroid extract.

Dr. Langstein counselled caution in arriving at conclusions regarding the value of these substances.

---

HUNGARY.

Budapest, Aug. 10th, 1914.

The Heart in Rheumatism in Children.

Dr. Benes and Desnever say that even the apparently mildest rheumatism in a child does not cause the slightest appreciable symptoms, may yet entail heart trouble, possibly fatal. This is accepted as a matter of course in acute articular rheumatism, in which the deviation of a joint, but it is not generally known that a slight attack of rheumatism with merely vague pains, or none at all, may be followed after a few weeks or months by a slight pain in the precordial region and dyspnoea. The heart beat is then often rapid and there may be evidences of old mitral insufficiency and recent pericardial friction sounds. The liver is slightly enlarged, the base of the lungs congested and the child is pale and languid, without appetite. Under rest in bed, ice to the heart, digitalis and the salicylates the symptoms subside and all seems well after four or five days. If the temperature is taken, however, it will be found a little above normal, and after a few days this syndrome occurs, to subside and return again. This alternation of symptoms is characteristic of the affection in question. No one imaging anything is seriously wrong until the terminal phase develops with the development of all the symptoms, vomiting and haemoptysis and the Cushing sign, without signs at any time of true asystolia, dropy or oedema. They have encountered twelve cases of this malignant rheumatic heart disease in children and discuss its characteristic features and the importance of vigorous salicylic medication in every case of rheumatism in a child, no matter how apparently mild, and the physician should watch over the heart afterwards. Every tachycardia, every pain in the heart region, with or without a Cushing sign, must be regarded as signs of serious trouble, especially when there is accentuation of the second pulmonal sound. This latter indicates not only the participation of the pericardium but also that the patient is not yet in the precordial regions, therefore, the physician advocates subcutaneous injections of sodium salicylate in twice the amount of water. From 2 to 5 gm. of this solution can be injected at one point without inducing a local reaction. Digitalis also relieves; the children with the affection seem to display a special tolerance for digitalis and the symptoms improve under it.

Diagnosis of Enlarged Thymus in Young Children.

Dr. Deak analyses the symptoms and signs suggesting hyperfunction of the thymus gland, being sometimes being that it is sometimes extremely difficult to distinguish between an unduly enlarged thymus and enlarged tracheobronchial glands as the cause of dyspnoea. He gives the details of twenty-one cases (twelve girls and nine boys) in which various points involved, including two in which he was certain that the thymus was hypertrophied, but an operation revealed atrophy of this gland, the enlarged tracheobronchial glands being responsible for the trouble. The special features of enlargement of the tracheobronchial glands are a history of measles, bronchitis or bronchopneumonia, the general lack of dulness over the manubrium, and difficulty in breath- ing which is more serious on inspiration, while the chest is retracted during inspiration, mainly in the lower portion, the depression occurring, if it occurs at all, simultaneously in the epigastrum, the lower sternum region and the hypochondrium on each side. The heart shadow is often above the transverse groove resulting from this form of retraction. Sometimes the groove curves up on each side, so that the chest above bulges spherically, while the retraction portends between the lungs on the sides. Röntgenography shows the normal chest with a shadow like a long necked bottle, while with enlarged thymus the shadow is irregular, with a protrusion just below the neck of the bottle on one side. The outline is smooth and the shadow even. With swollen lymph-nodes in the anterior mediastinum, the upper part of the shadow is as normal, but below it spreads out irregularly generally
on the right side of the shadow of the heart, the pro-
trusions small and round or finger-shaped, sloping
downward, and surrounded by several shadows with a circular outline, while the depth of the shadow may vary from that of the heart, being either lighter or darker.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

PROFESSORSHIP OF PATHOLOGY AT ABERDEEN.

The King has been pleased, on the recommendation of the Secretary for Scotland, to appoint Dr. Shennan, M.D., F.R.C.S.E., as Regius Professor of Pathology in the University of Aberdeen. Dr. Shennan is at present pathologist to the Royal Infirmary, Edinburgh, and has been engaged in teaching the subject almost since his graduation in 1890. He has worked in the pathological and bacteriological laboratories of London, Copenhagen and Munich. He has made a number of important contributions to our knowledge of tuberculous, particularly in the lungs, and his appointment is looked on as a well-deserved recognition of the work he has done.

BALDWIN INSTITUTION FOR MENTAL DEFECTIVES.

In the annual report of this well-known Scottish institution for the treatment of mental defect the changes, and the need for increased accommodation for defectives, which are foreshadowed by the passing of the Mental Defectives Act are referred to, but at present lack of capital has prevented the carrying out of the structural changes. It has lately, however, been found possible to carry into effect a desirable reform, and to separate completely from one another the children who are capable of being taught, and those who cannot. During the year 25 boys and 17 girls were admitted, and 12 boys and 13 girls discharged, the total inmates being 208. The hope is expressed that when the District Board of Control assumes the reins the present unsatisfactory state of matters—the sending of children too late, and their withdrawal without any provision being made for their future—will cease. For the rest, the report, and the opinions of the Lunacy Commissioners appended thereto, show that the Institution is doing its work in a satisfactory manner and is endeavouring during the transitional period to meet all the demands which the future may have in store.

EDINBURGH POST-GRADUATE COURSES.

Owing to the occurrence of the war, it has been decided not to hold the post-graduate courses in Edinburgh this year. The proximity of the North and East of Scotland to the North Sea, and the prospect of the various hospitals in the neighbourhood being drawn upon for military purposes, together with the general difficulty of business renders this decision regrettable necessity. It is felt that under the existing circumstances the post-graduate courses would not have been up to their previous standard, even as regards attendance or the quality of the work done, and it has therefore been thought better to allow them to remain in abeyance for this year.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

FORCIBLE FEEDING.

To the Editor of The Medical Press and Circular.

Sir,—I am loath to be at dispute with such distinguished champions of the militant suffragette as Sir Victor Horsley and the Hon. Secretary of the "Forcible Feeding Protest Committee." I should like to be allowed to ask these gentlemen, or any other whom it may concern, this very simple question: What do those who are opposed to so-called forcible feeding propose to substitute in lieu thereof in the event of a militant suffragette attempting to commit suicide by starvation? It is obvious on the face of this question that the prison officials cannot permit deliberate suicide without efforts to arrest a prisoner in the act, otherwise they would be necessary in law to a criminal act, hence they are driven to the insistence of taking food or forcible feeding.

On the other hand it seems equally clear that no law indemnifying the prison officials from responsibility, as was a law in England in 1914, could consistently be brought in so long as suicide is a felony or a criminal act, because under such circumstances the law, as it now stands, would be treating suicide as a criminal offence in one direction, and to all intents and purposes legalising it in another.

If, therefore, the suggestion of Sir Victor Horsley, the Bishop of London, and others, were adopted—that is to say, the entire dispensation or abrogation of forcible feeding, a militant suffragist would—as indeed they are for the most part now—be set free to commit another crime possibly more atrocious and drastically than the original crime, well knowing the immediate penalty could not be inflicted by the force of law. 

In conclusion, Sir, it is my answer to all this to say: "Then cast in your vote." This is merely evading the question of forcible feeding, and reverting to a political question which does not concern a medical journal. The entrenchment of women has nothing to do with either Sir Victor Horsley (so I understand him), with forcible feeding. On the other hand, it is essentially a medico-legal question, and as such I venture to intrude on your columns.

I am, Sir, yours truly,
CLEMENT H. SEES, M.R.C.S.
5, Chancotbury Road. August 7th, 1914.

NEO-MALTHUSIANISM.

To the Editor of The Medical Press and Circular.

Sir,—Since my last letter appeared activity has been given to a whole mass of factors bearing upon the international position of our peoples, the results of which have been touched upon in my previous communications. The book must be therefore closed upon these theories for the present; it would be grossly unseemly to discuss them at this moment, but there seems no reason why many of the principles included in what is styled "Neo-Malthusianism" should not be examined with advantage and propriety. It would be a great gain at the outset if we were clearly and explicitly informed of the Neo-Malthusianism. With my knowledge I can only interpret it as the cult of a doctrine which avows that most of the evils of the world can speedily be put an end to by a narrow limitation of the population. "Neo-Malthusian" charges me with "taking a limited view of the matter." He thinks "I am imbued with the idea of imperial domain both for France and England." This passage may serve as a fair sample of Neo-Malthusian's style throughout. It is vague; a solid statement is difficult to discover anywhere. Where does he really mean, for example, by "imperial domain"? He declares "that more important than the welfare of France or of England is the welfare of the world." The propagation of the Patagonians, Zulus, and the stationary backward races of the East is as important as that of the progressive peoples of the West. There is a passage in one of Charles Kingsley's books—it is quoted in the recently published life of Florence Nightingale—in which he points out the empty vast domains in British Colonies, and pleads for population of these territories by what he eloquently demonstrates is the finest race on earth—the Anglo-Saxon. He writes of the waste of infantile life in his time to neglect of sanitation alone; shows how the diseases keeping up the death-rate are mainly preventable, and
argues for the rearing of our broods by known methods in fixed and well-selected localities from which they may be distributed. We should not, indeed, be ashamed if our colonies be the nucleus of the future world. The world has already become the family of man, and the future history of mankind is to be written in purely geographical terms. The conditions under which we live and our economic institutions should be planned on a geographical basis, just as the plans of our cities, with the growth of the population and the rapid application of scientific knowledge, have become largely dependent upon the geographical conditions.

The conclusion of the essay is that the world is now a single unit, and that our common interests and ambitions should be based upon this fact. The thesis that our colonies may be the nucleus of the future world is supported by arguments that the conditions under which we live and our economic institutions should be planned on a geographical basis.

In the essay, the author concludes that the world is a single unit and that our common interests and ambitions should be based upon this fact. The thesis that our colonies may be the nucleus of the future world is supported by arguments that the conditions under which we live and our economic institutions should be planned on a geographical basis.

In the essay, the author concludes that the world is a single unit and that our common interests and ambitions should be based upon this fact. The thesis that our colonies may be the nucleus of the future world is supported by arguments that the conditions under which we live and our economic institutions should be planned on a geographical basis.
MEDICAL NEWS IN BRIEF.

A Tuberculosis Dispensary for the City.

The Local Government Board has approved the establishment, under the National Insurance Act, of the proposed tuberculous dispensary at St. Bartholomew's Hospital for a period expiring on October 31st, 1915. It is expected that the dispensary will be opened on November 1st, probably not without some ceremonial, though nothing has yet been definitely decided on that point. The Corporation, it is understood, has arranged to subsidise this interesting experiment for one year at an estimated annual expenditure of £500 to £700.

Royal Dublin Society.

We are asked by the Council of the Royal Dublin Society to announce that, in consequence of the present national emergency, and the occupation of the Society's premises at Balls Bridge by the military authorities, the Autumn Horse Show and the Art Industries Exhibition announced to be held on August 24th to 28th must be abandoned.

The Metropolitan Hospital Sunday Fund.

This Council of the Metropolitan Hospital Sunday Fund has last week under the presidency of Sir William Church. The sum of £291,457, the total of the fund for the year, was allocated in awards to 253 institutions, being less than last year. Of the total sum 4½ per cent. was appropriated to the purchase of surgical appliances and 24 per cent. for district nursing associations. Sir William Church was elected to represent the Fund on a committee which is dealing with the coordination of district nursing institutions.

Among the proposals recommended by the Committee of Distribution and approved by the Council for the year 1914 may be mentioned the following General Hospitals:—Charing Cross Hospital, £1,080; French Hospital, London, £2,250; Northern Central Hospital, £1,205; Guy's Hospital, £1,692; Hampstead and North-Western London Hospital, £712; Italian Hospital, £205; Kensington General Hospital, £570; King's College Hospital, £4,145; London Fever Hospital, £1,507; Phillips's Memorial Homoeopathic Hospital, £143; London Temperance Hospital, £608; Metropolitan Hospital, £1,707; Mildmay Homeopathic Hospital, £530; Walthamstow Hospital, £250; Miller Hospital and Royal Kent Dispensary, £54; Poplar Hospital, £537; Prince of Wales's General Hospital, £292; Royal Free Hospital, £1,276; St. George's Hospital, £2,041; SS. John and Elizabeth Hospital, £448; St. John's Hospital, £675; Lewisham, £221; St. Mary's Hospital, £1,875; St. Thomas's Hospital, £478; Seamen's Hospital Society, £1,400; The Middlesex Hospital and Convalescent Home, £2,461; St. George's; £1,830; Walthamstow, etc., Hospital, £140; Woodwharf, Bollingbrooke Hospital, £317; West Ham Hospital, £500; West London Hospital, £1,131; Westminster Hospital, £1,603.

Conjoint Board of England.

New Diplomas in Public Health.

NOTICES TO CORRESPONDENTS, &c.

Correspondents requiring a reply in this column are particularly requested to insert their names and addresses. No letter should be sent unless the action of the Committee is required, and to avoid the practice of signing themselves "Respectfully, "the name of the author shall be given. Such confusion will be spared by attention to this rule.

Original Articles or Letters intended for publication should be sent to the Editor only, and should be accompanied by the name and address of the writer, not necessarily for publication, but as an indication of identity, as the case may require.

Inquiries—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the Editor that they do not wish to prevent the distribution of their papers. This should be done when returning proofs.

DR. CHRISTOPHER ADDISON'S APPOINTMENT.

It was announced in the Liverpool Western Mail on July 31 that Dr. Christopher Addison, M.D., has been appointed Parliamentary Secretary to the Board of Education at Westminster.

The Metropolitan Asylums Board.

It is announced that the Metropolitan Asylums Board have raised the salaries of their medical staff by £20 a year in the case of the majority, with sums ranging between £30 and £70 in the case of senior officers.

Tuberculous Milk.

In America experience has decided that one-third of the milk supply comes from tuberculous cows, in which 5% per cent. show clinical disease. The cow is a very important animal in the demand for attention and inquiry in this country. The significance of the contagion is seen, and the control of such tuberculous infected milk must be consummated, which compels local sanitary authorities to take a comprehensive line of action.

H. T. M. (Swindon).—The cause of science and particularly of research must, necessarily, receive a severe check through the war. No germ may be used, can, of course, reach those shores for some time to come.

The New "British Pharmacopoeia." The General Medical Council has announced that the publication of the new edition of the "Pharmacopoeia" has been indefinitely postponed in view of the war and other changes.

Workmen's Compensation Act, 1906.

The Home Secretary gives notice that in consequence of the deaths of Dr. C. T. Vichell, one of the Medical Referees for Carlby and Hiley County Courts, and of Dr. J. R. Robertson, Medical Referee for the Shetland District of Caithness, Orkney, and Shetland, the appointments held by them are now vacant. Applications for the posts should be addressed to the Private Secretary, Home Office, Whitehall, S.W., and should reach him not later than the 30th August, 1914.

L. S. A. (Hertford).—The use of perchloride of iron was advocated some time ago for raising the blood. It cannot be said to be superior to iodine when employed as soon as the disease is recognised, but wherever possible radiotherapy is to be preferred.

Apostles' Hall of Ireland.

Correspondents are reminded that a fresh address for the apostles' hall of Ireland, with reference to supplying temporary surgeons for the Army and Navy in the existing national emergency, the apostles' hall have decided to hold a special qualifying examination on August 19th. Inducting candidates should communicate at once with the Registrar, Apostles' Hall, 40 Mary Street, Dublin.

Foreign Correspondence.

The usual letter of our French correspondent has not reached us this week. The letter of our Austrian correspondent came to hand as we were "at press" too late for our present issue; it is held over for our next.

Vacancies.

Certificate Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Dutable (Beds.), £200 per annum. Hulme Dispensary, Dale Street, Stretford Road, Manchester.—House Surgeon, Salary £150 per annum, Applications to Honorary Medical Secretary.

Ref. E. W. Ashton, Morningside.—Assistant Physician, Salary £150 per annum, Applications, with full particulars, to the Medical Superintendent.

Lancashire Education Office.—Two Assistant School Medical Officers. Salary commencing at £200, rising to £250 per annum, Applications to the Lancashire Education Office, to the Town Clerk of Municipal boroughs. (See advert.)

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer. Salary £150 per annum, Applications to Medical Superintendent, Cornwall County Asylum, Bodmin, (See advert.)

County Asylum, Whittingham, Preston, Lancashire.—Assistant Medical Officer. Salary £250 per annum, with board, furnished apartments, &c. Applications to the Medical Superintendent, (See advert.)

HULME DISPENSARY, DALE STREET, STRETFORD ROAD, MANCHESTER.

WANTED a HOUSE SURGEON duly registered and fully qualified. Salary £250 per annum. Annual increase of £25 per annum, Applications, with testimonials, at once to Honorary Medical Secretary.

Appointments.

DEBURY, PENNOX, L.R.C.P., L.R.C.S., I.M.R., Medical Superintendent, Royal Cornwall County Asylum, Bodmin.

GIBSON, E. W., M.C., M.C., Royal Medical and Dental Staff, Hospital for Inebriates, Banbury.

GIBSON, J. A., M.D., C.M., Medical Officer of Health of East Coast.

HINCH, CHARLES T. W., M.R.C.S., L.R.C.P.Lond., House Surgeon, Royal Dental Hospital, London.

SIME, EDWARD RICHARD EDWARDS, M.B., B.Ch., F.R.C.S., Education Officer, Royal Infirmary, Hull.

STACEY, W. G., M.R.C.S., L.R.C.P.Lond., Medical Superintendent of the State Institution for Mental Defectives at Moss Side, Liverpool.

Deaths.

ADAMS.—On August 7th, at Zürich, Switzerland, Henri Amédée, civil engineer, son of the late Louis Auguste Amédée, of Neuchâtel, to Alice Maud Dodd, M.B., B.S., eldest daughter of Arthur and Alice Dodd, of Fairlight, Redhill, Surrey.

BARKER.—On August 7th, at 51 Fourth Avenue, Hove, the wife of Roderic Arthur Clapham, M.A., M.D., of a daughter.

BELSHAW.—On July 14th, at Coimbatore, Southern India, the wife of Major Henry Belshaw, C.I.E., of Chesterton, Shropshire.

BRADLEY.—On August 1st, at 49 George Street, Portman Square, W., the wife of G. A. Aaron, M.A., M.B., M.R.C.S., of, of.

FRANKS.—On August 6th, at St. Oswin's, Upper Norwood, the wife of William Frankes, M.R.C.S., L.R.C.P., of.

Marriages.

ALLAN.—On August 20th, at Zurich, Switzerland, Henri Amédée, civil engineer, son of the late Louis Auguste Amédée, of Neuchâtel, to Alice Maud Dodd, M.B., B.S., eldest daughter of Arthur and Alice Dodd, of Fairlight, Redhill, Surrey.

BARKER.—On August 7th, at St. Peter's Church, Chichester, Captain R. E. Seymour-Swaby, M.S., second son of the Rev. R. H. Swaby, Chaplain of the 82nd (2nd South Lancashire) and 8th (Coldstream) Regiment, to Miss Sewell, of Jerusalem, and Mrs. Sewell, of Sutton Very Warmister, Wilts, to Dorothy, youngest daughter of the late William Town and Mrs. Dean, of Chichester.
To assert that disease claims a greater number of victims among armies in the field than injuries sustained in actual warfare is merely to state that which history records and past experience confirms. Since the fighting strength of troops is in direct proportion to their powers of physical endurance, the need for insisting upon the observance of the principles of military hygiene becomes paramount. We are glad to note that a memorandum upon the importance of early resort to antityphoid inoculation has recently been issued by the War Office. The risk of infection by uninfected typhoid carriers must always be reckoned with when large bodies of men are massed together in camp and are exposed to contact with the inhabitants of a country in which typhoid fever may be present. As a means of further safeguarding the health of our troops, it is understood that a new unit has been formed by the Royal Army Medical Corps, under the title of the Sanitation Corps. Consisting of one hundred trained officers and men, the new unit is to be entrusted with the special duty of testing food supplies and water, more especially with a view to the detection of poison, and they will also take charge of all sanitary arrangements. The prompt disinfection and removal of organic refuse and the adequate supply of pure food and water can best be carried out by officers specially versed in the science and art of military sanitation.

**Open-air Hospitals for the Wounded.**

Among the numerous offers of help received by the War Office in the shape of housing accommodation for the sick and wounded are many buildings such as schools, dwelling-houses, church institutes, etc. However much one may appreciate the generosity of the donors, it is obvious that the construction of many of these buildings is most ill-adapted for the reception of patients. As Professor Robert Sandlau has pointed out in a recent letter to the Times, an abundance of light and fresh air are a sine qua non in the treatment of the sick and wounded. These essentials are not always conspicuous even in modern buildings, unless they have been specially designed, while in many more ancient habitations they are so lacking as to render them wholly unsuitable receptacles for the sick. Professor Sandlau’s condemnation of the policy of “converting” buildings not intended to serve as hospitals, and his plea for a greater use of balconies and the erection of sheds in public parks, are based upon a sound recognition of the value of open-air in the treatment, not only of consumption, but also of diseases and injuries the results of war. Needless expense and damage to property may both be avoided by the putting up of temporary open-air hospitals in convenient situations. The managers of those hospitals that are fortunate enough to possess gardens or balconies attached to wards know full well their value in reducing the average length of stay of in-patients, whilst institutions deprived of these accessories to convalescence are correspondingly handicapped.

**Hospital Routine in War Time.**

Since so many of the visiting and resident staffs of the voluntary hospitals have either been called away or have offered themselves for active service with the Forces, some re-arrangement of the ordinary routine of hospital life must necessarily follow. In some cases out-patients are being discouraged, only urgent cases being received as casualties. At one large provincial infirmary the out-patients’ waiting-hall has been converted into a sick ward, the patients themselves being asked to attend at an adjacent public dispensary. As a large number of hospitals have agreed to place a certain number of their beds at the disposal of the War Office the view has been expressed in some quarters that the claims of the poor in the immediate vicinity of the institutions in question will suffer in consequence. It should be stated at once, in justice to the hospital authorities and in the interests of the public, that every possible means will be taken to prevent the infliction of any hardships upon the regular clientele, so to speak, of the civil hospitals. Under ordinary circumstances a number of incurable cases are admitted to general hospitals for short periods for teaching purposes or for the trial of some new therapeutic method. There are also certain surgical cases in which the postponement of an operation for a few weeks, or even months, will not prejudice the health of the patient. Here are two classes of cases, therefore, that need not be admitted when the exigencies of war demand bed space for the treatment of the sick and wounded in action.

**A Little Extra Squeezing of Beds.**

The Doctor’s may be legitimately allowed in an occasion of emergency such as may arise at any moment, though in times of peace any overcrowding would, of course, be justly condemned by a watchful medical superintendent. Not only in his capacity as a hospital physician or surgeon is the civilian-medical practitioner directly affected by the war. In many other ways his practice is influenced, whether this be of a consulting, cash, or panel character. At a special meeting of the South Western Branch of the British Medical Association held at Exeter the other day, the need was discussed for approaching the
military authorities with a view to the consideration of the question of locomotion for medical men, as if their horses or motor-cars were requisitioned for service medical work in certain districts would come to a standstill. We understand that the Association itself has made no move in this respect to the War Office, urging that medical practitioners’ horses and cars, especially in country districts, should not be taken by the military authorities, except as a last resource. It is of the greatest importance that all delays in providing medical assistance to sick persons should be avoided, particularly at the present time when the hands of most medical men are extra full. It is gratifying, therefore, to learn that the Army Council has issued orders to the effect that where possible the horses, and in all cases the motor-cars, of country practitioners should not be requisitioned.

SEVERAL of the Universities and other examining bodies have risen Unqualified to the occasion and have announced Help, that they are prepared to hold a special final examination to enable candidates who have completed their medical training to qualify as soon as possible, so that they can offer for active service. In all directions offers of help, free or at cost, have been announced for the dependants of Regulars or Reservists or even for the men themselves at the various general and special hospitals. It is not surprising to find that the unqualified person, seeing an opening for self-advertisement, has edged his way to the front, for in the Daily Graphic, dated August 19th, we read that a certain Mr. Frank Matthews, the well-known bone and joint specialist, offers his services to the military authorities . . . either at his surgery in Charing Cross Road or at the military bases. Mr. Matthews will hold himself in readiness to be at the command of the authorities at a moment’s notice.” Since we have failed to find the name of this enterprising gentleman in the Medical Register, we may presume that the authorities will politely ignore his offers of “assistance.” Bones and joints are too important parts of our anatomy to be trifled with, much less to be “treated” when out of gear by anyone not in possession of a registrable medical qualification. Perhaps the General Medical Council may have something to say in the matter. The camp-follower in medicine is always a person to be regarded with mistrust and to be kept at a respectful distance.

LEADING ARTICLES.

IS CANCER INFECTIOUS?

Those members of the public who have been induced to favour the Times as their daily newspaper, by its reduction in price, must have been struck by the similarity which its columns bear to another journal of the same group, under the same proprietorship. The policy of the editors of the journals concerned seems to be, that having once published an article assuming a particular position, to ensure that no opportunity is afforded the public, in their columns, of learning the other side of the question, beyond meeting the demands of immediate journalistic expediency. This policy may be considered in the trivial matters of ordinary life; even if it amuses the more discerning of the readers of the journals concerned, the public are not likely to suffer from its practice. The case, however, is very different when questions of medical importance are similarly dealt with. By this means the public are liable to be much misled; to form opinions which are erroneous, or to adopt popular notions, which are opposed to scientific teaching. In this respect, we think, the editor of the Times has been unwise in leading the readers of that journal to suppose that cancer is infectious. Some weeks ago the Times published an article dealing with the question of so-called cancer houses. The impression conveyed by that article was the scientifically absurd one that houses in which multiple cases of cancer occurred were the locales of cancer infection. Then followed the usual correspondence in support of that view, and a very few on the other side were published in which its absurdity was portrayed. In short, the editor having made himself responsible, as a layman, for the assertion that cancer was probably infectious, avoided himself of his position to maintain it, despite the evil consequences which the assumption of that belief would be liable to create in the minds of his readers. A very grievous result has now probably followed. Naturally, it has been argued, if houses can become the source of cancerous infection, why not persons who are suffering from cancer? That is to say, the effect of the dissemination of this unproved doctrine has probably already led to serious aggravation of the misery of the victims of incurable cancer who are now liable to be regarded askance and avoided as though they were suffering from some deadly infectious disease.

Until the germ of cancer has been definitely isolated, if, indeed, it be caused by a micro-organism at all, we are not in a position to say deliberately whether malignant disease be infectious or not. Recent research would appear to favour the view that there is no danger whatsoever of infection, but the public, unfortunately, will scarcely be satisfied with a mere expression of opinion, even though this emanate from a high scientific authority. Thus does a leading lay journal, in attempting to discuss matters of medical concern, become the medium of the dissemination of misconception and errors of fact the absorption of which by the public mind is calculated to be productive of an inconceivable amount of mischief. The fact that the Times should have raised the question of cancer houses at all only emphasises once again the need which exists in this country for an inquiry into the subject of cancer by a Royal Commission. The director of the Cancer Research Fund has always strenuously opposed this suggestion. He has now a concrete example of the inexpediency of his opposition. Public opinion could not avail itself against the considered and weighty report of a Royal Commission, but public opinion has been created in favour of the infectivity of cancer and cancer houses, a subject which the commission would have very properly and naturally dealt with, and nothing
THE TREATMENT OF LEG ULCER.

At a visit to the casualty, surgical, or dermatological department of any large hospital one may generally come across several cases of ulcer of the leg of all grades of severity. The treatment of these lesions always seems more or less of a reproach to medical science, for it is mostly handicapped by the fact that the patients are seldom able to rest the limb. The ambulant treatment, therefore, of an ulcerated leg, be it varicose or of an uncertain origin, presents a clinical problem which is not easy of solution. If syphilis be the cause of the ulcer the treatment is somewhat easier, for in the face of modern specific remedies few syphilitic ulcers refuse to heal. It is the large, indolent and sloughing ulcers, with evidences of deficient nutrition and impaired vitality, that sometimes prove a veritable bugbear to the practitioner. From time to time the appearance of a new drug or method which promises to promote rapid cicatrization is hailed with delight, only to fall into disuse after trial. It may be that sufficient attention is not paid to the technique of the application, especially to the preparation of the base of the ulcer first, for it is little use applying any healing agent in the presence of active suppuration. It has been said that most, if not all, ulcers of the legs will disappear after prolonged rest in bed and ordinary cleanliness, and there is a good deal of truth in the assertion. But the practitioner will seldom be able to enforce such a period of rest, for the majority of cases of ulcerated legs occurs in working folk who have to be up and about. The most he can do is to strap the ulcer, or apply a zine-gelatin-paste with bandaging of the whole limb. If he wax enthusiastic over one of the newer cell-proliferants he frequently has his ardour dampened by the complaint of the patient of the pain and irritation produced thereby. When the use of certain aniline dyes, notably scarlet red and fuchsins, came into vogue for the treatment of leg ulcer, it was thought that at last the perfect remedy had been discovered. Similarly, with the discovery of allantoin in the root of the common comfrey, our hopes were once more raised. It must be admitted, however, that the use of these remedies, intelligently applied, having due regard for individual idiosyncrasy, has constituted some advance, if slight, in the therapeutics of leg ulcer. The whole subject has been ably reviewed by Dr. A. Ravogli (a) in a paper read before the Section of Dermatology at the Sixty-Fifth Annual Session of the American Medical Association, at Atlantic City, N. J., in June last. The typical stages of ulceration are divided into those of necrosis, sloughing and repairation, and upon these periods depends the selection of the treatment. In the first stage the application of pastes is regarded as judicious, weak solutions of sodium bicarbonate or bichromate being preferred. The use of nascent oxygen, ichthyol, or boric ointment is to be preferred in the second stage, while the process of repairation must be carefully watched over, all young granulations being protected from infection and irritation, so that excessive proliferation may not occur. The practice of massage or of the division of the cutaneous nerves surrounding the ulcer, after the manner of Nussbaum, may be advisable to assist the final process of healing. At the same time, the internal treatment of associated morbid conditions cannot be dispensed with. Provided that every indication for treatment be duly recognised and suitably met, there is no reason why the treatment of chronic leg ulcer should not be placed upon a more satisfactory footing than it has hitherto been.

CURRENT TOPICS.

The Profession in Ireland and the War.

It is impossible as yet to foresee to what extent the ordinary conditions of professional life in Ireland are going to be affected by the war. Comparatively few medical men in that country are connected with the Territorial Forces, though many have promised their services to one or other of the two bodies of Volunteers. If the Volunteers are organised and taken over by the Crown the services of these gentlemen will doubtless be required. In the meantime nearly all the young qualified men in the country have offered themselves for active service, though up to the present few have been called. There is, indeed, some discontent among these young men at the fact that those who personally offered themselves at the War Office have been selected in priority to those who, in obedience to instructions, handed in their names at Dublin Castle. There is little doubt, however, that in time they will all be wanted. Their departure will inevitably cause some difficulty in the working of the hospitals, as most capable and spirited young practitioners will prefer the chance of service in the field to the comparatively hum-drum routine of a house surgeon's work. The several licensing bodies are, it is true, endeavouring to meet the unusual demand by holding special final examinations. Perhaps a more serious inconvenience to the hospitals is caused by the calling in the hospital reserves, and the volunteering for service of nurses who were not in the reserve. In another way, the sudden demand for training in first aid and home nursing work is affecting medical practitioners. Classes are being rapidly formed, and an appeal has been made by the St. John Ambulance Association to the members of the staffs of the Dublin hospitals to

assist by giving lectures in first aid, home nursing, and ambulance work. So great is the interest in such work at present that there is a danger that many persons, whether or physicians or students or surgical or nursing work, will join the classes and prove a hindrance to really effective progress. We notice that certain of the Dublin hospitals are accepting a limited number of young women for work in the wards for periods of training of a few weeks. The wisdom of such a course is open to question.

The Results of the Friedmann Treatment.

It is only within the past few months that it is possible to form an opinion of the results of the treatment of tuberculosis carried out in America by Friedmann early last year. Dr. Maimheimer, of New York, has recently (a) published a note on the present condition of eighteen patients treated under his supervision by Friedmann. The results are certainly not encouraging. In no less than seven cases abscesses developed at the site of injection. Of the entire number of patients three were lost sight of, and three are known to be dead. Of the others who are still under observation, in seven the disease progressed and in five the condition is unchanged. It is obvious that the results are not any better than might have been expected without the use of any special form of treatment. The occurrence of abscesses as the direct result of inoculation in so high a proportion of cases is distinctly disquieting, and the claim of Friedmann's that his vaccine is innocuous, judged by results, therefore, there does not seem to be any further justification for the use of Friedmann's preparation, and, as he has refused to divulge the secret of its manufacture, we are prevented from forming any opinion as to the possibility of eliminating the evil results.

The Healing Power of Nature.

Such is the mystery of human existence that the supreme efforts of art and science, combined for the relief of the physical woes of mankind, are powerless to influence the processes of disease, unless they act in accordance with or otherwise assist the operations of Nature. This mighty hidden factor is directly under observation and in certain conditions, for Nature is quick to resent any interference with her methods and plans, and she wreaks fierce vengeance, long-delayed, perhaps, but nevertheless unrelenting, upon the too self-reliant practitioner who has left her out of his reckoning. In spite of her sternness, Nature is in most cases a sure, if a slow, healer. There are those in the present day who claim loudly for "Nature study" and "Nature cures," unmindful of the fact that the most successful physicians, teachers, and philosophers are those who, consciously or unwittingly, follow Nature's principles and imitate her methods. It was a happy thought that inspired Dr. J. Arthur Thomson, K.B., the Professor of Natural History of the University of Aberdeen, to select for his "Popular Lecture" delivered at the recent annual meeting of the British Medical Association at Aberdeen the subject of the "Six Medicatrix Nature." Full of the most interesting and instructive biological allusions, Dr. Thomson's able discourse fully vindicated the propriety of delivering a scientific address to which laymen are invited as well as medical men. We all, professional men and laymen alike, and especially theformer, need to be reminded of the healing power of Nature, particularly in the way in which she ministers to our minds, only too often distracted by the wear and tear of modern civilization, by steadying and enriching our lives with beautiful impressions.

Summer Drinks.

In the summer time all men's fancies turn to thoughts of liquid refreshment. By which statement we do not mean to imply the unwholesomeness of cool imbibitions in other seasons of the year, but in the summer the call of the cup becomes insistent. Now there is a vast but often unrecognized difference between liquids and drinks. Liquids for our present purpose are the fluid essences of our physiology. Drinks are something more. They usually lack the crude ordinariness of necessity which is replaced by qualities appealing alike to our conscious senses and aesthetic attention. They may be divided into two classes, those which contain alcohol and those which are supposed not to be in this category. The first class is easily dealt with. It consists of wines, diluted spirits, and the various beers. Its qualities are familiar and its consumption immense. The second class is vaguer and more variegated. Probably one of the chief reasons for the admittedly too great consumption of alcohol is the non-existence of a non-alcoholic beverage that is worth drinking. One would think that a pleasant drink with some character and a few real qualities, which are not situated in the present day, it is the least little, glass of artificial drinks are terrible. They consist mostly of sugar and CO₂ in solution with clovey, pungent or bitter flavouring. A few sips make a full man, not a happy, satisfied man, but an aerated one with his attention centred on his distended epigastrium. It must be bad for him, but that does not affect the retailers. "Minerals," are cheap, handy, and show a large margin of profit, and the public seems to demand effervescence. CO₂ tickles its palate and temporarily increases its flow of saliva. In a short time it wants another bottle. That is why we live in a time of effervescent bibularity.

Medical Journalism in Australia.

The appearance of the first number of the Medical Journal of Australia, dated July 4th, betokens the incorporation of the Australasian Medical Gazette and the Australian Medical Journal as the one official journal of the Australian branches of the British Medical Association. Union is strength, and there can be no doubt that the result of the amalgamation of the two journals above-mentioned will be a concentration, as well as a conservation, of energy and a considerable gain to the members of the British Medical Association in Australia. Under the able editorship of Dr. H. W. Armit, who is well known in London medico-literary circles, the journal has promised well. And it need not fear that their representative journal will not faithfully reflect the progress of scientific medicine or fail to give a decisive lead in matters of medico-political importance. In the leading article of the new issue we read that "a scientific journal is not judged according to its standard of literary excellence. It is purposeful—it sets the mark of the thing—which is paramount; the form of expression is subsidiary." Only to the chosen few is it given to clothe crude scientific facts in the attractive literary garb of a Ruskin. Nevertheless, we venture to assert that the style of our medical journals, regarded as a whole, is in no wise inferior to that
of other technical periodicals. In the words of Dr. A. L. Kenny, the President of the Victorian Branch of the British Medical Association, we heartily extend to our new contemporary and to its leader the wish, "Prosper, prodeo, et regna."

Sanitary Service in War Time.

We have already called attention in these columns to the effect upon the health of the community of the rapid withdrawal of large numbers of medical men from the country. The shortage of qualified practitioners is bound to react upon the physical welfare of the public, unless special means are taken to prevent such a calamity. The Local Government Board, after due consideration of the latest developments, has just issued a circular to county councils and sanitary authorities, drawing attention to the supreme importance of maintaining the efficiency of the sanitary service of the country at the present time. It is pointed out that it is essential that there should be no relaxation of any of the activities of local authorities in the prevention and control of epidemic diseases, the protection of water supplies from contamination, the promotion of child welfare, and in the securing the wholesomeness of food supplies and the general sanitary condition of each area. On this account, therefore, it is imperative that all vacancies in the minor sanitary offices shall be filled up.

Many steps which may be open to local authorities to replace medical officers of health who are absent on naval or military duty will vary in different districts. In many areas adequate temporary arrangements may be made by co-operation between the county council and district authorities or between neighbouring district authorities. The Board will be glad to be informed of each case in which a medical officer of health or chief sanitary inspector or inspector of nuisances has been given leave of absence for naval and military service, and of the steps taken to arrange for the temporary discharge of his duties. Only in this manner can it be hoped to carry on the sanitary service of the country without any break and consequent loopholes for disease to creep in unsuspected.

Photography in Medicine.

Of all the ancillary arts and sciences that have come to the aid of medicine photography may justly be reckoned one of the most important. No record of disease can be said to be complete without a photograph depicting the morbid condition, such as the size and extent of a tumour, the facial expression, the existence of some deformity or rare configuration of surface, etc. The camera has also proved a valuable detective, as when the existence of a meases rash is revealed on the photographic plate before it has become visible to the eye. It is superfluous to mention the extreme aid that photography has rendered to surgery in conjunction with the X-rays. To be a pathological photographer, or rather a photographer of pathological objects demands a good deal of special skill. The lack of this is constantly seen when ordinary photographic artists are asked to take some interesting morbid condition of the body. The resulting print, unless special instructions have been given, generally results in the display of an abundance of clothes and background, while the interesting eruption or growth is quite small and inconspicuous. Another more recent development of the photographic art which has just begun to demonstrate its utility for illustrating morbid pathological conditions, and not a few modern medical text-books have taken advantage of the method for special plates. The Paget method appears to promise great things in the direction of the faithful reproduction in natural colours of pathological subjects. Several transparencies of cases of skin disease made by this process were in evidence in the museum at the annual meeting of the British Medical Association at Aberdeen, and they were unanimously voted a striking success.

The Shick Reaction.

The present is an age of laboratory tests and specific reactions. With the growth in our knowledge of bacteriology and serum-therapy this must inevitably be the case. One result is that the art of diagnosis is in danger of being reduced to a question of minute figures and the interpretation of the consequent reaction. The latest test of this kind is known as the "Shick reaction" in diphtheria, an account of the practical application of which is given by Drs. W. H. Park, A. Zinger, and H. M. Serotu, of the Research Laboratory, Department of Health, New York City (a). The reaction depends upon the local reaction of minute quantities of diphtheria toxin when injected intracutaneously. If antitoxin be absent or in insufficient quantity for protection, a positive reaction appears in twenty-four to forty-eight hours, consisting of a circumscribed area of redness and slight infiltration, measuring from 1 to 2 cm. in diameter. This persists for about a week and gradually fades, leaving a brownish pigmentation. To prevent the appearance of the reaction it is estimated by Shick that at least one-thirtieth of an unit of antitoxin per c.c. of blood is required, but Behring states that so small a quantity as one-hundredth part of an unit of antitoxin will protect against the disease in uncomplicated cases.

The authors tested the reaction in 700 patients, and they find that the test serves as a reliable and convenient index of the susceptibility or otherwise of individuals to diphtheria. It is also of service in the diagnosis of clinically doubtful nasal diphtheria. The Shick reaction may, therefore, be regarded as a useful adjunct to our means of detecting diphtheritic infection.

PERSONAL.

Dr. H. S. Birkett has been appointed Dean of the Medical Faculty of McGill University, Montreal.

Dr. Bethel A. Solomonos, F.R.C.P.I., has been appointed Visiting Gynaecologist to Mercer's Hospital, Dublin.

Mr. H. G. Parker, F.R.C.S.Edin., L.R.C.P.Edin., has been appointed Honorary Aural Surgeon to the Bolton Infirmary and Dispensary.

Dr. James Carrick, M.B., B.S.Glas., Assistant Medical Officer of Health for Paisley, has been appointed an Assistant Tuberculosis Officer for Sheffield.

Dr. Henry Pratt Newsomle, M.B., B.Ch.Oxon., M.R.C.P., D.P.H., at present Assistant Medical Officer of Health for the county borough of Southend, has been appointed to a like position in the Surrey county health department.

Mr. Walter Joseph Harper, L.R.C.P.Lond., M.R.C.S.Eng., of Braunton, Devon, was the recipient the other day of a suitable testimonial as a mark of esteem and affection upon the occasion of his retirement from practice in the district.

CLINICAL LECTURE

ON

DIAGNOSTIC APHORISMS IN GYNECOLOGY. (a)

By ARTHUR E. GILES, M.D., B.Sc., F.R.C.S.,

Surgeon to the Chelsea Hospital for Women; Gynaecologist to the Prince of Wales' Hospital, Tottenham.

As "aphorism" is defined as "a concise statement of a principle in science," and this definition expresses with sufficient accuracy what I wish to convey in the present remarks. That is to say, I want to place before you in concise form some of the principles that are helpful in gynaecological diagnosis.

I must premise that the statement of a principle implies a generalisation, and a generalisation is an expression of a substantial truth combined with a fractional element of error.

Aphorisms are not free from this flaw. They are general truths containing a germ of error; in other words they formulate the general rules and probabilities, and do not take cognisance of the exceptions and possibilities.

Such aphorisms as I have to offer you are therefore intended to suggest the truth in diagnosis; but they do not claim to represent "the whole truth and nothing but the truth."

**Of Diagnosis in General.**

A few observations on diagnosis in general may be permitted. The first is that a diagnosis based on symptoms and unsupported by an examination of physical signs contravenes the fundamental principles of medical ethics; and anyone treating a patient on the strength of such a diagnosis might very well be regarded as "guilty of conduct infamous in a professional respect."

Without entering upon the merits or demerits of the Insurance Act and contract practice, I may say that if the "panel system" fosters the treatment of the poor on the basis of their symptoms and without due examination, that system is a dishonour to the medical profession.

I have seen the phrase, "We make mistakes; other people commit sins." A wrong diagnosis after due examination (a thing that happens to all of us) is a mistake, and a pardonable one; a wrong diagnosis (without due examination) is a thing that happens to the other fellows) is a sin; medically speaking, it is "the unpardonable sin."

That an examination was not allowed is no excuse for a wrong diagnosis. If you cannot convince the patient that an examination is necessary, quit the case; for it is better to lose a patient than to lose reputation. Moreover, do not treat first and examine afterwards; for then you may be called upon to treat not only the disease, but also the effects of your own treatment.

After an examination has been made, if still in doubt admit it. If you do not know enough about the case to satisfy yourself, it is not safe to assume that you know enough about it to satisfy the patient; this is not only indifferent ethics, but also bad policy. A celebrated American politician once said: "You can fool all the people some of the time, and you can fool part of the people all the time, but you cannot fool all the people all the time."

While I am giving advice I may offer this piece to the beginner: When in doubt, do not commit yourself to a diagnosis and then call in a specialist, for this may tax the specialist's ingenuity too severely.

A final word of advice may prove wholesome for the specialist as well as for the beginner. In the presence of the obvious, do not overlook the possible; it does not follow, because you have found something, that there is nothing else.

**Of Pregnancy.**

Probably more mistakes are made about pregnancy than about any other condition in gynaecology.

When a woman says that she menstruates during pregnancy, either she does not menstruate or she is not pregnant. Menstruation is a preparation for pregnancy, and when this has arrived Nature is not so fickle as to go on preparing for it.

Pregnancy can never be excluded on _a priori_ grounds of spinsterhood, widowhood, separation, social position, religious belief, political "convictions," or the alleged previous removal of organs; nor on the patient's affirmation that it is impossible.

Some women cannot be convinced that they are pregnant until they see the baby, and not always then. It is unsafe to state, on the ground of the condition of a woman's pelvic organs, that she cannot become pregnant unless you have yourself removed her uterus, ovaries and tubes, and even then it is wiser to say that it is improbable.

There are many symptoms and signs of pregnancy, and all of them can be simulated save one: the one infallible sign is to hear the fetal heart.

In doubtful cases it is to be remembered that pregnancy may be complicated by the presence of other conditions.

**Of Tumours.**

Speaking generally, during the child-bearing period, a tumour with missed monthly periods is pregnancy; a tumour with unaltered menstruation is non-uterine; a tumour with increased menstruation is a fibroid. When a woman has a large tumour, if she is very thin it is probably ovarian; if she is very fat it is probably uterine fibroid. We may vary this observation by saying that cystic tumours are associated with wasting, and solid tumours, except malignant ones, with adiposity.

A fixed tumour in a woman at or past the menopause suggests malignancy; in a young woman it suggests an inflammatory mass or an inflamed tumour.

A supposed ovarian cyst can sometimes be removed by passing a catheter, and a supposed solid tumour by giving an enema.

When a woman in her teens or early twenties has an irregular tumour suggesting fibroids, look out for pus tubes. Fibroids are rare before the age of twenty-five.

A swelling in connection with the uterine appendages may be a small ovarian cyst, tubo-ovarian inflammation or tubal pregnancy. The physical signs of the three conditions may be indistinguishable, and the diagnosis will turn on the history.

Speaking generally:—

An adnexal tumour without symptoms is ovarian.
An adnexal tumour with or following xanthorrhæa is tubo-ovarian.

An adnexal tumour with scanty haemorrhage following mixed periods is tubal pregnancy.

If a swelling is found, the probabilities are against tubo-ovarian inflammation; if it is bilateral, the probabilities are against tubal pregnancy.

It is well not to assume too readily that there is a tumour only on one side merely because none can be felt on the other.

When small, firm tumour can be felt on the left side, it is well to make a rectal examination. Such a tumour may be a carcinoma of the rectum or of the sigmoid.

With an adnexal tumour, the temperature is an indifferent guide. It may be normal with pus-tubes, and it may be raised with tubal pregnancy and with an ovarian tumour with twisted pedicle.

When symptoms and signs point to an inflammatory mass in the pelvis, the channel of infection should be sought. Infection conveyed up the unbroken genital tract leads to salpingitis, pus-tubes and peritonitis; infection carried through the broken genital tract leads to pelvic cellulitis and pelvic abscesses. When the symptoms and signs of a pelvic tumour are not classical, imperative difficulties and complications may be expected.

Of UTERINE CANCER.

When haemorrhage occurs after the menopause, with no previous history of menorrhagia, the condition must be regarded as carcinoma until the contrary is proved.

Cancer of the vaginal portion of the cervix is found only in parous women. Cancer of the body of the uterus is found nearly exclusively in nulliparae. Endo-cervical cancer is found in both, but much more often in parous women.

The treatment of uterine haemorrhage without examination at or after the menopause closely resembles manslaughter.

The scantier the haemorrhage, the greater the urgency; for profuse haemorrhage is nearly always due to simple tumours, whereas haemorrhage due to cancer is nearly always scanty, except in the late stages. Hardness of the cervix is not a sign of malignancy; friability is. Wasting and an offensive watery discharge are not essential to the diagnosis of cancer. They are rare when the disease is far advanced. When a woman has cancer of the uterus, the younger she is the worse is the prognosis.

Of EXTRA-UTERINE PREGNANCY.

A history of missed periods, followed by a brown discharge, leaves the thoughtful physician pondering on the subject of tubal pregnancy until the diagnosis is settled.

With a history of early miscarriage and no focus passed, a ruptured tubal pregnancy must be thought of.

Missed periods followed by median pains and free loss suggest uterine miscarriage; but, if followed by lateral pain and scanty loss, extra-uterine pregnancy.

When tubal pregnancy is associated with uterine haemorrhage, the tube has always ruptured or aborted, and the gravid tube and hematocele become a fixed mass. Therefore, a mobile tumour associated with uterine haemorrhage is not a tubal pregnancy.

The pregnancy may be closely simulated by a retroverted or laterally deviated gravid uterus, and by a small ovarian cyst or distended tube associated with an early impending miscarriage.

Of THE MENOPAUSE.

Normally, the menopause is no more a critical period than is puberty; the cessation of menstruation should be as uneventful as its onset, but both epochs are liable to be associated with some functional disturbance. The menopause may engender functional disorders but does not cause disease. Disease may, however, be synchronous with the menopause.

Menstrual infrequency or diminution in the flow may be functional, and attributable to the approaching menopause.

Increase in the frequency or the amount of loss is due to disease.

Increase in haemorrhage at or near the time of the menopause, or any haemorrhage at all after the menopause, renders an immediate examination necessary.

The menopause does not cure disease any more than it causes it. To tell a patient to wait for the menopause is as bad as sending her to a quack.

Of SYMPTOMATIC DISORDERS.

Dysmenorrhœa and menorrhagia are not pathological entities, but symptoms of which the cause must be ascertained.

When dyspareunia is present from the first, it is usually due to uterine stenosis or vaginitis; when it comes on later, it is usually due to tubo-ovarian disease.

When coitus is followed by haemorrhage in later life, look out for urethral caruncle, cervical polyposis, and malignant disease.

When sterility is accompanied and associated with dysmenorrhœa, it is probably due to uterine and ante-plexion; when it is associated with a history of xanthorrhœa, it is probably due to salpingitis.

When sterility is not associated with definite physical signs, the husband should be examined before the wife is treated.

When a woman complains of pelvic pains assume that there is a definite physical cause until such has been excluded.

Never call a woman neurotic when you do not know the condition of her pelvic organs.

The LAST WORD.

There is no sign or symptom that may not be fallacious. The most experienced judgment is fallible.

Note.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by R. Oswald Moon, M.D., Oxon., F.R.C.P.Lond., Consulting Physician to the Western General Dispensary, Marylebone; Physician to the Hospital for Diseases of the Chest. Subject: "Mitral Stenosis, its Prognosis and Treatment."

ORIGINAL PAPERS.

ACUTE GENERALISED INFECTIVE PARALYSES IN ADULTS.

By W. B. Warrington, M.D., F.R.C.P., Hon. Assistant Physician, Royal Infirmary; Examiner in Medicine, The University of London; late Physician to the Northern Hospital, Liverpool.

Every now and then we are confronted in practice by cases of rapid and widespread paralysis the extent of which is so great as to cause much alarm, sometimes justifiable. No obvious cause is, as a rule, to be discerned. Although paralyses of this acute nature present marked similarity, yet that they are of a different pathology is proved by the course of the disease and the marked difference in prognosis. Several acute diseases may attack the nervous axis and its peripheral nerves and bring about an extensive paralysis: (a)

(i) Acute toxic polynicræ—cause agent is rarely recognisable, and few opportunities have occurred for a study of the anatomical basis.
Acute poliomyelitis—doubtless due to the same infective organism which causes the ordinary form of infantile paralysis, and characterized by the same pathological lesions.

Electrical examination—a disease the nosological position of which has been much discussed, but which, in the writer’s view, is certainly a distinct clinical and probably an equally distinct pathological entity. The importance of a diagnosis is obvious when it is stated that in acute toxic polyneuritis the terminations begin abruptly; complete recovery by Landry’s paralysis the event is either rapid death or complete recovery; whilst in poliomyelitis a fatal result is rare but some permanent damage usually remains.

I shall give a typical illustration of these several types, and also add an account of a case of acute ascending myelitis, which, although comparable was a very acute and terrible course, yet if its symptoms are known can hardly be confounded with the other forms. A particular feature of interest attached to this case is that the evidence seems to show that it was due to the organism of mumps, certainly a most rare sequela, though this disease sometimes has cerebral and meningeal complications.

Acute toxic polyneuritis.—Thomas J. was a young man of twenty-two years of age. He was a total abstainer and of previous good health. The only antecedent of any importance which could be discovered was that for the last few months he had constantly been wet through.

His chief trouble was headache, vomiting, and paraesthesia of tingling and numbness in the feet and hands. It is not known whether he was feverish; the course of the disease during the time he was under observation was afebrile. Weakness soon appeared in the legs, and in a week he was unable to stand. If he were supported and attempted to walk, he moved his limbs about in a wild and vacillating manner. On examination of the muscular power, both lower limbs were greatly affected, but the distal parts much more so than the proximal segments, so that, whilst he could barely move his feet or toes, there was some power in the knee-joint and even more in the hip. Slight wasting in the front of the leg was evident at first. The appreciation of loss of power was found to be present in the upper limbs: the small muscles of the hand were distinctly wasted, the grasp and movements of the interossei weak, whilst the larger elbow and shoulder joints retained a fair amount of power.

The cranial nerves also shared in the paralysis; the lower part of the face on the left side and the left vocal cord were obviously weakened in their movements. The remaining cranial nerves were normal; and at the time he was first seen the thorax, abdominal muscles, and the diaphragm were acting well. There, was no affection of the sphincters.

Electrical testing showed distinct diminution, though not an absence of, faradic excitability in the weakened muscles.

A striking feature was the muscular hyperesthesia, but we were not able to detect any loss of cutaneous sensation or inability to appreciate passive movement. All the deep reflexes were absent, but the abdominal, cremasteric, and plantar reflexes were present. A slow but uneventful progress to complete recovery took place.

The diagnosis was not difficult, but, before commenting on this case, I will relate an example of generalised paralysis which I have recently met, and am still in some doubt whether we have to deal with polyneuritis or poliomyelitis.

Mr. W., a patient of Dr. Sélater, aged twenty-six years, was quite well on the day previous to the onset of this illness, which began with a feeling of weakness and feebleness, vomiting, slight fever, and a dry patch on the knick of his throat. At the end of a week double vision appeared, but this only lasted for a few days. This symptom came on before any signs of paralysis. Then the left leg became weak, and, the loss of power rapidly invading all four limbs, he was not able to sit up or move at all, and there was "twitching" all over the body.

There was no difficulty in swallowing, nor any other affection of the cranial nerves. There was a slight hesitancy in passing water, but no other bladder trouble. Pains in the thighs were marked, and there was a great tenderness of these muscles. No tingling of the feet or fingers was evident, and he apparently began to improve rapidly.

About three weeks later, in the right upper limb there was distinct atrophy of the first dorsal incosseous muscle, though this and the other small muscles of the hand could be moved, but the second or third fingers could not be extended. The deltoid was very feeble, but all the other muscles showed some, though diminished, power. In the left upper limb the deltoid was powerless, but all the other muscles, including the small muscles of the hand, could be moved. The right lower limb had recovered and could be lifted from off the bed, and he could extend the toes, although the paralysis was more marked in the feet than in the muscles of the thigh. In the left lower limb the loss of power was extreme, and only very slight movement was possible in the knee-joint and hip-joint, and there was nearly as much power present in the extensors of the feet. There was no loss of sensation either superficial or deep. The diaphragm and thorax were acting well. The ankle-jerks and the knee-jerks were gone; the planter response was feeble, but the abdominal and the epigastric reflexes were brisk. Electrical testing showed that all the muscles of the upper limbs reacted to faradism. The right deltoid gave a very feeble response, and with the right trieps the response was just barely perceptible. The left deltoid responded feebly, but the triceps, latissimus dorsi and pectoralis acted fairly well. All the muscles of the right lower limb acted to a strong current, but the only muscle excitable in the left lower limb was the quadriceps.

From personal experience and the studies of Dr. Farquhar Buzzard, the following are the points on which one mainly relies in making a diagnosis:

<table>
<thead>
<tr>
<th>Toxic Polyneuritis</th>
<th>Poliomyelitis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Onset</td>
<td>Quick, but not sudden, malaise, fever.</td>
</tr>
<tr>
<td>Extent of paralysis</td>
<td>Limbs and especially their peripheral parts most affected, trunk may be invaded, and direct marked incision of the skin is possible.</td>
</tr>
<tr>
<td>Cranial nerves</td>
<td>Face most commonly affected, sometimes vocal cord, palate, oesophagus nerves.</td>
</tr>
<tr>
<td>Sensory</td>
<td>Muscular hyperesthesia, sometimes in the face, and slight objective loss of sensation.</td>
</tr>
<tr>
<td>Superficial reflex</td>
<td>Usually lost or diminished.</td>
</tr>
<tr>
<td>Electrical reaction</td>
<td>Usually lost or diminished.</td>
</tr>
</tbody>
</table>

Mr. W. was a typical case of "papilledema."
It has been my fortune to see two cases of Landry's paralysis with complete recovery. If the opportunity occurs to watch this paralysis from its inception, I do not think its diagnosis presents great difficulties.

The steady march upwards, segment by segment, the paralysis of the abdomen and thorax, and then of the diaphragm, which may cause the fatal termination; or, if this is escaped as it were by a hair's-breadth, from some remaining excitability of the respiratory muscles, the progress of the disease to attack the centres in the medulla, again threatening life, makes the typical disease at least a striking and dramatic picture.

The first case that I relate I saw with Dr. Shaw a number of years ago. M. was a young man of 20 years of age, who had suffered an illness, supposed to be influenza, some two weeks previously, which compelled him to stay in bed for about ten days. He then went back to his work, and on the Wednesday; suffered from pains in his legs, of a dull, aching character, and accompanied of a feeling of numbness and tingling in the feet and in the fingers. He was seen by me on the Sunday, four days later, and was then lying helplessly in bed. The lower limbs were greatly paralysed, so that he could not lift them from off the bed; there was practically no movement in the psoas-isiacus group and barely perceptible power of abduction and adduction of the thigh muscles. There was the typical power to movement in the upper limbs, and he was able to make very slight movement of the ankle-join; the calf muscles appeared to be weaker than the extensor.

In the upper limbs the shoulder girdle muscles were markedly affected, and also the muscular movement of the elbow-joint. The wrist and the fingers were also parietal, but the loss of power was not so great as in the larger muscles of the abdomen, and the diaphragm moved well. The optic discs were normal, and there was no objective disturbance of sensation. Knee-jerks and ankle-jerks were absent, and also the plantar and epi-gastric reflexes. All the paralysed muscles acted strongly to faradism.

On Tuesday the patient was worse, and with the exception that he could extend the toes, the lower limbs were absolutely paralysed. The weakness had also progressed in the upper limbs, so that now he could not make any movement with the fingers or wrist; and although the loss of power in the shoulder girdle remained very great, the weakness did not seem to have progressed as much in the muscles moving the wrist and fingers. The thorax barely moved in respiration, and the diaphragmatic contraction was feeble.

The cranial nerves were now affected, and there was complete left-sided paralysis of the face and of the palate. The speech was slow, drawn, and monotonous, but there was no difficulty in swallowing.

The optic discs and eye muscles were normal. All the muscles still reacted to faradism.

On Thursday the absolute powerlessness of all the four limbs continued, the patient's face was still paralysed, and there was now difficulty in swallowing. The speech had somewhat improved, but the thorax showed some signs of expansion, and the diaphragm was also acting a little. The pulse was about 100, and the temperature raised a degree or so. There was no trouble with the sphincters, and the patient's mind was quite clear. Gradual recovery occurred and was complete.

The second case was very similar; my patient was a young man, aged 26, who a few days before he came under observation complained of stiffness and unsteadiness about his feet, and a day or two later of a difficulty in using his arms.

When I saw him, about a week after the onset, the lower limbs were paralysed, and flaccid; all he could do was to feebly flex the thigh; the reflexes were absent, but sensation and electrical irritability remained. I found the abdominal and thoracic muscles and the diaphragm to be acting well. The upper limbs were also greatly paralysed. The muscles which move the wrist and fingers and the elbow-joint were practically powerless, and there was very little power in the small muscles of the hands. Above this level the muscles of the head, shoulder, and neck acted well.

He remained in this state for a week; then the paralysis advanced, the intercostals and abdominal muscles being paralysed, so that breathing was almost entirely by the diaphragm. The muscles of the neck became weakened, the sterno-mastoids were almost powerless, the face on the left side was paralysed, and the larynx barely moved with phonation or in swallowing.

At this stage the patient could not make the slightest effort to sit up or flex his head; dia-phragmatic respiration appeared the minimum, dyspnoe became pronounced, respiration appeared almost to depend on the activity of the trapezius and the pectoral muscles.

Next the right side of the face became paralysed, and one felt that the slightest further spread of the disease must be fatal.

After another week in this precarious state the intercostals began to expand the thorax, and power in the diaphragm returned, the face regained tone; then the muscles of the shoulders, the arms and hands; next the legs, the neck muscles, and the back muscles began to recover. Improvement continued, so that in five weeks, from being in a most desperate condition, the patient was able to sit up. Power rapidly returned, and in another week he could walk with a little help, whilst in a fortnight he was convalescent. Throughout the disease there was no atrophy of the muscles, no loss of sensation, no alteration in the electrical reactions, and no affection of the bladder.

The diagnosis of Landry's paralysis, if the case can be watched for a day or two, may perhaps be so difficult. At the onset the pain and constitutional disturbance are less than in either toxic poliomyelitis or poliomyelitis. The electrical reactions are of great importance.

Landry's paralysis is often fatal, and it has long been known that in these cases the muscles were excitable to the end.

My two cases show that this capacity for response continues, and at once forms a certain diagnostic point in distinction from poliomyelitis and almost so from toxic poliureutis.

In conclusion, I relate the case of acute ascending myelitis, at once distinguished by the gross loss of sensation and the affection of the sphincters. My patient was a young man, aged 15, who, with brother, some ten days previously, bilateral parotitis, diagnosed, no doubt correctly, as mumps. On the Friday she complained of pain at the back of the neck, was up and walked on the following day, but had eventually to give up on account of the pains. On Sunday the pains were worse, especially on movement, and on Monday weakness in the legs and numbness set in. On Tuesday night the temperature rose to 101°, and she was slightly delirious. I saw her on the Wednesday, and she was lying in bed with her head kept to the left. She was moving restless, with clouded mind, but there was no obvious paralysis of deglutition or articulation, though she spoke with difficulty, the
words lacking their normal volume, and she said that it seemed to her as if the food stuck on the back of her throat.

There was nystagmus in all directions, of long range and slow rhythm. The optic discs were normal. There was complete flaccid paralysis, with absent reflexes of the sphincter and relex was absent. The bladder was distended and dribbled.

The thorax was paralysed, but the muscles of the shoulder girdle supplied by the upper cervical roots and the diaphragm were acting well.

There was total anaesthesia on the right side up to the fifth dorsal segment, and on the left as far as the first lumbar segment. Above this, diminished sensation as high as the neck-body line—i.e., to the level of the second dorsal—and this loss of sensation could be traced along the inner border of the upper limbs. There was obviously, therefore, an affection of the spinal cord reaching up to, but not involving, the fifth or sixth cervical segment. In the upper limbs there was great paralysis, especially in the fingers and the small muscles of the hand. The muscles supplied by fifth and sixth roots acted fairly well.

A week later the patient was obviously much worse; the face was cyanosed, little air was entering the lungs, and bubbling rales were heard. The thorax and abdomen were completely paralysed, the respiratory function was maintained by the feeble action of the diaphragm. The girl was wandering, the disease had spread into the higher part of the cervical enlargement, and anaesthesia had become almost absolute. Death occurred two days later.

TWO CASES ILLUSTRATING THE USE OF THE DIURETIC THEOCIN-SODIUM-ACETATE.

By CHARLES PEDDIE, M.A., A.MED., M.R.C.P.

Medical Officer for the Brindley District, and Certifying Factory Surgeon, Chorley, Lancs.

Before beginning the description of the cases I may say that I have always employed the following formula:

R. Theocin-sodium-acetate, gr. 80
Tr. Digitalis, dr. iss
Tr. Sella, dr. iiij
Casc. Evacuant., dr. 1
Acq. oz. ad. viij
Sig.—A tablespoonful every four hours until further orders.

The tinctures I have prepared from Parke, Davis & Co's. fluid extracts made up to the proper strength with glycerine and chloroform water. In this way the use of alcohol, undesirable in kidney cases, is easily avoided. The preparation of fresh infusions advised by some writers is impossible for the busy practitioner and I have never had any cause to complain of the digitalis prepared as above.

Case 1.—Male, 47.—This patient had been under the care of another medical practitioner for four months during which time instead of improving he gradually got worse. When I saw him first in February, 1911, there was extensive oedema of the lower extremities and a fair amount of ascites. He was also very much troubled with "dry bearing" as well as almost continuous belching of wind, a symptom very common in heart cases, and causing only momentary relief (this is a purely nervous condition, its cause is obscure and may be insufficient blood supply to the stomach) and also suffered from insomnia, which was exceedingly difficult to relieve. The urine was loaded with albumen.

The first point of attack was the heaving and collecting of wind in the stomach, and this I was able to influence by hypnotic suggestion, the insomnia being also relieved by the same means. The suggestions were renewed twice a week for about three weeks and then discontinued. I prescribed the theocin-sodium-acetate mixture for him with remarkable results; the pain dropped entirely disappeared within a fortnight's time, and the albumen was very rapidly, His intake of fluids was limited in order to assist the absorption as well as the elimination of fluids from the tissues. The biliary attacks and the blood pressure symptoms were treated as they arose.

The dietary prescribed was as follows:—

Breakfast, 8.30.—An egg lightly boiled, poached, or fried in bacon fat, with a little toast well buttered when cold. (I have found it an advantage in the preparation of toast to have it dried first in the oven before toasting in order to ensure its being crisp).

Dinner, 5 p.m.—Fish, fowl or chop with green vegetables cooked with plenty of butter.

Tea, 5 p.m.—A little China or decaffeinated tea.

Supper.—Repetition of dinner with the exception that it was varied—if he had fish at mid-day he would get a chop or fowl in the evening etc.

He was a life-long teetotaller and a tablespoonful of brandy was prescribed with a little hot water, before he settled down for the night. It should be noted that he had very little milk, and practically a saltless diet.

In the end I was rewarded by his complete recovery in about five months.

He resumed work in the beginning of July and from that time until his death on October 21st, 1913, he never lost a day's work, even though he was kept at it from 6 a.m. until 6 p.m., without the chance of getting home for his meals. He did lose 3 hours' work about 3 weeks after commencing, but this was due to a bilious attack, brought on by a six-mile walk on Saturday, in a boiling sun. He thus remained perfectly well for 2 years and 4 months. On Monday, the 20th October, 1913, he returned from work, complaining of a slight pain in the chest and feeling a little out of sorts. On retiring, the pain gradually got worse, and about 7 a.m. I was telephoned for, but on arrival found that death had ensued from heart failure.

Case 2.—Male, 57.—In November of 1912 a patient consulted me, complaining of shortness of breath and inability to get through his work with the wonted ease. On examination I found nothing organically wrong, but the patient was exceedingly stout and had been overworked, and I believe the heart action had been interfered with on account of the fat. There was no trace of albumen or sugar in the urine. I prescribed a heart tonic combined with a mild diaphoretic, and strongly advised a holiday, which, however, he was unable to take.

I did not see him again for nearly a year, and heard that he was being attended by another practitioner. I was informed that on September 18th, 1913, he was sent to see a specialist in Liverpool who gave the prognosis that with rest and careful dietary he would get perfectly well. On October 1st, I was asked to take the case, which had been given up as hopeless by the bowen towns acting for his usual attendant. When I saw him he was in a semi-comatose condition, fighting for breath, the pulse rate being 136. He had oedema of the lower extremities and great scrotal swelling.
LIME SALTS IN CHILDREN'S DISEASES. (o)

By J. C. McWALTER, M.A., M.D., F.F.P., and S.

All diseased children have deficient lime in their tissues, and a smaller proportion of calcium in their bones. All weak animals have less lime in the osseous framework than their healthy brethren. At once it seems sound sense and rational therapy to give some sort of lime to a delicate child, but so soon as we do we encounter the pharmacologist who assures us that our labour is in vain, and our attempt but a proof of our ignorance. We are assured, in fact, that all these efforts to introduce lime into the system are futile, and that none of it is retained—that normally, in fact, it passes out unchanged.

Two or three incidents have lately tended to resurrect the faith of the profession in the efficacy of lime salts. One is the marvellous influence which the administration of thyroid substance has in certain developmental diseases of infancy. Coincident with these observed good results comes a theory that hypothyroidism results in an excretion, or at best the inability to absorb in the salts containing the necessary salts—as chloride of sodium, phosphate of lime, etc. We have then staring us in the face the broad fact that metabolism is impossible without calcium, that the simplest tissues hunger for it, and are rendered powerless to function or to grow without it, and the defective growth, as well as all diseased conditions, are associated with a deficiency of calcium compounds. There is the further important fact of which the French school attach great importance—namely, that tuberculosis is, chemically, a decaying process, that its essential manifestation is an exaggerated excretion of calcic and other salts, and that in the face of deficient tissue supplies, have be in increasing the intake of suitable mineral salts, mostly calcie.

If lime salts do good, how shall we give them? Lime water is an old and favourite remedy, but the pharmacologists tell us that it only acts as a simple alkali, and represents nothing more than a dilution of the salt, which brings about a more rapid dilution of the urine and reduces the amount of lime in the body. The mothers of families, seems to prove a real influence in lime water in modifying intestinal and stomachic disorders, which certainly is not exhibited by a weak solution of potash or soda.

Lime water, we shall agree, is useful, but the half grain or so of lime which it contains per ounce is certainly a weakly way of giving a calcium salt. Much more useful is a solution, now almost gone out of use, the saccharated solution of lime, which contains about 14 times as much lime as lime water. Children who in their earlier years are probably given some suitable salt of lime, are liable to the disease of deciduous teeth, to hemorrhage if the Eisen temperature system is broken down, to tuberculosis affections, especially of the bones, than those whose lime content is subnormal. Fixity of tissue is the result of sufficient lime content in the organism. The bones are hard, wiry-like; the teeth are strong; there is no tendency to fluxes, whether of the intestinal tract, the mucous membranes, or from the nascent system.

A very suitable way to give calcium is in the form of powder—carbonate of calcium and precipitated phosphate of calcium. They can be mixed with sugar or sugar of milk, and may be given at much less about half-hour or doses twice or thrice daily, blended with a little milk.

The pharmacologists will assure us that these salts are perfectly inert, and pass out unchanged. Possibly this may be true of 0.5 per cent. of the salt—if all remained in the organism doubly so. Retention would give rise to the formation of insoluble salts, to hemmorhage if the Eisen temperature is broken down, to tuberculosis affections, especially of the bones, than those whose lime content is subnormal. Fixity of tissue is the result of sufficient lime content in the organism. The bones are hard, wiry-like; the teeth are strong; there is no tendency to fluxes, whether of the intestinal tract, the mucous membranes, or from the nascent system.
THE CHOICE OF THE METHOD OF OPERATION IN THE TREATMENT OF GASTRIC AND DUODENAL ULCER, WITH A REVIEW OF MY EXPERIENCE ACCUMULATED IN THE LAST TEN YEARS. (a)

BY PROF. FREIH. VON EISELSBERG, M.D.,
Vienna.

In spite of all the progress in the diagnostics of gastro-intestinal diseases, amongst which 1 place Rontgen photography amongst, the choice of the method of operation in gastric ulcer and its complications can best be made at the autopsy in vivo when the abdominal cavity is opened.

It is most important that the operator should satisfy himself whether there is an ulcer on the surface or a healed ulcer—in fact a scar—and whether the ulcer is situated at the pylorus or at a distance from it. When in possession of these facts he is in a position to decide which operation is to be recommended, whether gastro-enterostomy only, or pylorus exclusion, or, lastly, a resection.

The operations for the acute and chronic conditions met with in gastric ulcer are amongst the finest achievements of modern surgery.

That the operation of the straitifying one is justified and justly fills the surgeon with pride and satisfaction will be confessed by anyone who has witnessed how a patient with an acute perforation of a gastric ulcer is rescued from the deathbed on which he was found by laparotomy, irrigation of the peritoneal cavity and incision of the ulcer.

Or, again, how a patient with a chronic pyloric stricture is relieved of his chronic illness and weakness and converted into a healthy and flourishing human being.

Gastro-enterostomy especially has come to be considered as an operation most frequently attended with beneficial results, and today there is no operation so often done in the gastro-intestinal canal—excepting, of course, surgical treatment of ulcers—whether we use the method as an universal method of treatment in all cases of ulcerated processes of the stomach, where it is possible to do it.

But the happy results of gastro-enterostomy just now mentioned are not evident in all cases. In cases of persistent ulcer particularly its cures are not so numerous as in the cases of ulcers already healed. In cases when the ulceration is at a distance from the pylorus, the results of gastro-enterostomy is not so good as in cases when the ulceration is situated at the pylorus. To my pupil, Claimont, especially is due the credit of having shown this.

And, finally, one must always bear in mind that peptic ulcer is not merely a matter of the underlying cause but that tumour formation, in which cases obviously only removal is efficient, while a gastro-enterostomy can have, at most, a palliative value.

In consideration of the fact that gastro-enterostomy has become so usual in the treatment of gastric ulcers, it behoves us to look very carefully into its merits.

My deductions will be particularly directed to this question: the value of gastro-enterostomy as compared with other operations for gastric ulcer; and especially will I define the position of the stomach.

My former pupil, Prof. Claimont, has helped me very considerably in the collecting and arranging of this great mass of material. He will shortly publish a large work going with our united experiences in the department of the operative treatment of gastric ulcer. Out of a total of 334 operations of gastro-enterostomy for gastric ulcer, 17 died after the operation (in 12 of these cases the ulceration was on the pylorus; number 8 died from causes referable to the ulcer itself for instance haemorrhage from the ulcer, progressive ulceration). Thus it will be seen that gastro-enterostomy in some cases not only did not stop the haemorrhage, but apparently induced it.

Of the 32 "unrelieved" cases in 8 the ulcer was situated at the pylorus; in 11 the ulcer was situated at a distance from the pylorus; 8 were duodenal ulcers: in 4 the situation of the ulcer was not known; there were adhesions, and probably it was a question of duodenal ulcers in these cases—total, 31.

The interesting point is demonstrated: that ulcers situated at a distance from the pylorus (Pylorunfen) are, by a long way, not so much influenced by gastro-enterostomy as those situated at the pylorus.

Standing at the head of the causes which are responsible for this failure of the operation to cure is the development of a post-operation—peptic ulcer of the jejunum.

This occurred 7 times in 334 gastro-enterostomies. Of this formidable complication after gastro-enterostomy I will speak fully later on. Finally, with regard to the cases shown under the heading "died at a later period," only a limited number of causes of death are known.

(i) 13 patients died of cancer of the stomach (or about 10 per cent.).

(ii) In 6 cases continuance of the growth and development of the ulcer after the operation was the cause of death: (a) 1 patient developed the morphia habit through the pain he suffered and died; (b) 1 haemorrhage caused death; (c) 1 death followed perforation of the ulcer; (d) 1 patient suffered pain and haemorrhage—jejunostomy was performed, but the patient committed suicide; (e) in 1 case the pains continued, but further details are unknown.

(iii) 3 patients died of tuberculosic of the lungs.

(iv) 1 patient died of acute cholecystitis.

(v) The cause of death in the remainder of the patients is unknown.

We see, therefore, that of 41 patients who died a long time—more than 17 years—after the operation of gastro-enterostomy, 13 (that is, nearly one-third) died of carcinoma, whilst 6 died through the progressive continuance of the symptoms of the ulcer.

In 36 cases of ulcerative processes of the stomach and duodenum these ulcers were of ulcerative type and pylorus exclusion was performed. This operation was in some instances done in the case of still ulcerated and bleeding ulcers in the neighbourhood of the pylorus, and in some instances cases of ulcers localised in the duodenum, for which situation pylorus exclusion appears to be especially suitable. Twelve operations were performed during 1911; the interval after operation is too short.

Eleven patients made a complete recovery after the operation. Some of these belong to the years 1905 and 1906.

Under the heading "improved" are included even cases complaining of insignificant symptoms. They might show most of them under the heading "cured.

Of the 4 cases which were "unrelieved" it is to be noted:

(i) In one case the extirpation of the whole ulcer was done for continuance of the pains, with the result that a cure followed.

(ii) One patient still suffers from attacks of haemorrhage.

(iii) Two patients developed symptoms of peptic ulcers.

Finally 3 cases died at a later date, about whom the following is to be noted:

(i) One case developed cancer of the stomach.

(ii) Two patients developed peptic ulcer.

SOME REMARKS ON PEPTIC ULCER.

As the topic of the development of peptic ulcer again occurs before me, I should like to go into the subject with more details, especially as it seems to me that the knowledge of peptic ulcer of jejunum is not so general as it deserves to be.

As H. Braun of Göttingen, the discoverer of this serious complication of gastro-enterostomy, has already pointed out, peptic ulcer appears to be caused by the continuous passage of the acid gastric juice into the small intestine (duodenum), causing the mucous membrane to be eroded and giving rise to the growth of an ulcer of the same size in varying intensities. In the less severe degrees symptoms taking the form of simple pains, such as an ulcer usually causes, can occur. In such a case—as in all

operative processes—repair on the part of the organism can bring about a cure. In these cases of spontaneous cure the contracting structure and stricture of the gastro-enterostomy wound area seems to take place very easily. I cannot explain in any other way what I have already observed. In other cases, however, the Kehr described case of Vienna—namely, the *shrinkage* of the gastro-enterostomy fistula, which I made of normal size to one-third of its size without any appreciable induration occurring, is the only case of this kind to which I can compare the above-mentioned case of Kehr. In other cases the fistula itself spares width, and with the serious and tragical issues of this we have hitherto to deal to-day.

I have observed the formation of a peptic ulcer 7 times in 317 gastro-enterostomies. Added to this I have found 10 peptic ulcers by other surgeons and on whom I myself did a relaparotomy, so that in all 12 patients a peptic ulcer was verified at the autopsy in vivo. Finally came 4 patients in addition in whom by the aid of a peptic ulcer followed unilateral pylorus exclusion. In these 17 cases the chief symptom was the development of a very painful in duration in the neighborhood of the gastro-enterostomy fistula, the discomfort and pain becoming so great that not a single person could eat or drink. In these cases the diagnosis of peptic ulcer was verified by the subsequent relaparotomy. Two patients were not operated on. Either another gastro-enterostomy, jejunostomy or finally an excision of the whole ulcer was carried out. In these 2 cases more than one of these operations was done either on one occasion or in several stages.

My table of the cases in which peptic ulcer developed shows that in six patients a fresh gastro-enterostomy was done, which was relaparotomized, but the ulcer itself was otherwise not touched. Only one of these patients was substantially improved after an interval of 6 months. One was unrelieved, one was lost. Two others died, one of the two fatal cases dying immediately after the operation. In the other the resection of the pyloric stump and the other later from the relapse of the ulcer.

In one patient, as the gastro-enterostomy did not give the hoped for relief, jejunostomy was done in addition, and in this case the stomach was entirely placed out of action. Here, on the contrary, the laparotomy was done on July 27th, 1912, when an ulcer was found in the duodenum, for which unilateral pylorus exclusion was done. After operation the acidity did not diminish—anyhow, not so much as usual—and hemorrhage kept occurring. October 16th another relaparotomy was done and a very large peptic ulcer was found, which seemed to be non-operative. A jejunostomy was now done, and a completely satisfactory improvement took place. The patient believed himself nearly well the second. I in turn urgently wished to dispense with the catheter. Unfortunately we yielded to the very strongly expressed wish—alas! all too soon. The catheter was left out, and the fistula had spontaneously closed on January 27th, 1913, 5 months after the relaparotomy. This case is very high, and the patient appeared to me to be lost. This man had too high an amount of hydrochloric acid, and one should not have dispensed with the jejunostomy so soon. Maybe one could still treat him successfully with adrenalin injection. In the present case, a female patient we obtained a favorable result with jejunostomy alone. A girl, at 27 (who in her seventh year had been successfully operated on by Billroth for hydatid of the liver), had pains in the stomach, moderate losses of blood and the constitutional symptoms of stenosis of the stomach. June 7th, 1910, gastro-enterostomy retro-colica posterior was done. Soon after the commencement of a good recovery a hard tumor in the abdomen developed, attached to the jejunum and extended to the wall. Suspecting a peptic ulcer, relaparotomy was done, and the suspicion proved to be correct. In consideration of the extension of the tumor, and the fact that it was intimately connected with surrounding parts, an ulcero-jejunostomy was done. It was done nearly three months after the first operation.

The patient for three years was given all her food by the fistula, and the tumor disappeared entirely, so that one was able to feed her from above and allow the fistula three or four times in the day. Simple removal of the catheter was sufficient, and the patient has now been quite cured for 2 years. This case illustrates the success of jejunostomy.

In the case of another patient with gastro-enterostomy and jejunostomy, one operation was done on the same day. This operation had been done upon September 25th, 1909, for a very high general acidity combined with an unhealed ulcer which extended into the duodenum; a unilateral pylorus exclusion was done. No improvement occurred, and the patient was relaparotomized on January 22nd, 1910, and a peptic ulcer found situated at the place of the gastro-enterostomy. Therefore a new gastro-enterostomy anticoelia anterior, plus entero-anastomosis, was done, and a jejunostomy as well was done. The patient died with symptoms of hematemesis. At the post-mortem five recent ulcers were found distal to the jejunum stump; one of the ulcers was on the point of perforation. The base of the old gastro-enterostomy was an annular ulcer, which appeared to be turning into a gastro-colica fistula.

In two cases first gastro-enterostomy and then the resection of the peptic ulcer was done. One patient had to be operated on 4 times, a gastro-enterostomy anticoelia anterior plus entero-anastomosis were done. One month’s relief from symptoms followed, then stomach trouble again occurred and the development of a tumor in the neighborhood of the whole ulcer. In the neighborhood of the ulcer, on June 17th, 1911, a second relaparotomy was done, the ulcer peptic was resected widely, the incisions passing through the quite normal tissue, and a fresh gasstro-enterostomy anticoelia anterior entero-anastomosis made. There followed an improvement lasting only a short time, and stomach trouble again set in, and on November 30th, 1911, the patient died with symptoms of a gastro-colica fistula.

Finally in three cases resection of the whole ulcer was performed. Of course, at the same time a fresh gastro-enterostomy fistula was established. This was necessary because we could not make a direct suture of the wound of the fistula.

In the case of the patient with a fresh gastro-enterostomy retro-colica posterior anastomosis was applied after resection of the peptic ulcer, whereas upon there was at last improvement. In the case of the second patient the subsequent history was lost sight of. One patient died after this resection. In this case the growth of a peptic ulcer of the jejunum presents a very serious complication; even repeated operations where really severe measures are employed are useless, and patients have succumbed to their peptic ulcer at last. Other authors have also repeated radical measures are necessary. Of these authors I mention v. Haberer, of the Innbruck clinic.

If we inquire into the causes of these ulcerous ulcers with hydrochloric acid value of the ulcer, it must be mentioned before. In some cases the patient had vascul
lar disease, either an arthritis and enteritis or a periarthritis.

It is observed this formidable complication of peptic ulcer in a surprisingly large number of cases and I cannot tell why I should have met with it more frequently than other surgeons. I should not like to say how much technique has to do with it. Peptic ulcers appear to me to be more frequent during the last years, and I am inclined to attribute its frequency to the fact that open or unhealed ulcers are operated on more frequently than before.

It is certain that many ulcers which are known to cause much tumorous formation and severe symptoms have led surgeons to think that cancer was present, and so the question of further operations has been laid aside.

Care must in the after treatment of cases possibly go far in the prevention of the development of peptic ulcer. For peptic ulcer which has already declared itself a total excision is the best treatment.

A short time ago I operated on just such a case, on which the primary gastro-enterostomy was performed elsewhere—an exceptionally difficult one, where the whole peptic ulcer together with the loop was excised.

I made the blind suture of both openings of the jejunum, and then the implantation of the distal one with a long loop of the stomach to the distal one. So far the progress of the cure has been rather satisfactory.

What I wish to emphasise is that whenever possible the patient must be excised, and that we make no experience neither gastro-enterostomy nor jejunostomy are sufficient in themselves, and in many cases both operations combined are of no avail.

We have already mentioned among the cases five patients on whom the first gastro-enterostomy operation was performed by other surgeons. I am therefore somewhat sceptical when I hear from other surgeons that they have never met with a peptic ulcer.

Cases in which Excision of the Ulcer was Done.

In the nine cases of death after operation the following proved to be the cases:

(a) Six times post-operative peritonitis—namely: four times caused by leakage of gastric juice (in spite of the strongly acid gastric juice the discharge from the ulcers was of a weak alkaline nature; it has repeatedly been shown to contain streptococci); once caused by leakage of the duodenal stump; once a chronic peritonitis was present.

(b) On a patient pylorus resection after method Billroth I, had been performed, where a fatal hemorrhage. In this case the total acidity was enormously high—so high even resection was unable to prevent the repeated formation of an ulcer. This patient had a very strong tendency to the development of peptic ulcer.

(c) One patient died later from the formation of a new ulcer, which perforated.

(d) One patient died forty-eight days after the operation method Billroth I, had been performed. He died of a secondary stenosis of the gastro-duodenal suture. In this case a gastro-enterostomy might easily have been helpful.

Subsequent Results of Resection.

(4) The 41 cases shown as cured are all quite well but of these there were 1 operated on in 1913.

(6) First improved and subsequently operated on. (1) In one case only an excision of the ulcer and at the same time a gastro-enterostomy retro-colica posterior was performed; (2) in one case a resection by method Billroth II, was made.

(c) Unrelieved 21. (1) In this case a wedge-shaped excision of the ulcer was done, then stenosis at the place of excision followed, and therefore gastro-enterostomy ante-colica anterior plus enterostomies was performed. This is direct evidence against the method of excision of the ulcer, and the operation should be replaced by resection. Whether in this case the repeated formation of the ulcer was traceable to a process analogous to the formation of a peptic ulcer must be left undecided. Wedge-shaped resection can easily lead to a sharp kinking of the vessels, and so may lead to a disturbance in the circulation and its resulting consequences—such as cicatrices or perforations. (2) One case resection Billroth II, 1911. Patient had recurrence of the trouble. Died 2.

(d) One patient died after three years of stomach trouble; one patient died after three years two months of cancer.

Subsequent results of resections (Table 5) showed good results. 41 cases are cured.

In the case of improvement followed by relapse after resection (Billroth II) had been done, it should be observed that the patient was well for 14 years, and then began to suffer pain in the left side.

The second case of excision which was not cured had relaparotomy performed on account of recurring trouble. In spite of a wedge-shaped resection a stenosis of the duodenal suture had formed. Finally, in a series of cases jejunostomy alone was performed. We need not wonder at the high mortality of the operation, as it was performed in the weakest and the most of all the cases, when the conditions were so complicated and nothing else was possible, or where the patients were so weak and worn out that one could only do the shortest operation it was possible to do under local anaesthesia. There are 24 cases with 12 deaths. Of these:

8 died of peritonitis.

1 died of hemorrhage from the ulcer, in other words, hemorrhage in spite of the jejunostomy.

1 patient was found to have tubercular complications, from which he died.

1 died of degeneration of the heart muscle.

1 died of marmasus.

Twelve cases survived the operation. Of these 2 died later, both of carcinoma.

1 case was improved.

4 cases were lost sight of.

5 cases were completely cured.

So we can lay down the following

Rules for the Choice of Method of operation on the basis of our observation:

(1) For acute perforation the best method is the earliest laparotomy, with irrigation of the peritoneal cavity and closure of the orifice of the perforation. Whether gastro-enterostomy should be done afterwards depends on the situation of the ulcer and the general condition of the patient. If the patient is so weak that a gastro-enterostomy is out of the question, and can take nothing on account of the peritonitis being already far advanced, then jejunostomy is the most simple operation, as it makes it possible to feed the patient uninterrupted for a long time.

I will here remark that in other complication of ulcer which we fear so much—namely, hemorrhage, operation is in most cases better left alone. When the hemorrhage is severe, expectant treatment is best, for it has repeatedly occurred at the operation that the bleeding point could not be found. This is one of the most hopeless situations in which a surgeon can find himself, for the patient may die during the operation. On the other hand, it is surprising how much blood a patient may lose without dying. One can stop a good deal of hemorrhage with rest in bed, ice bags to stomach, injections of gelatine, serum of horses, the administration of calcium lactium. In hopeless cases we can make use of strong chloride (1 in 1,000) solution for irrigation. In extreme cases jejunostomy should be performed, as one can give the stomach absolute rest and at the same time give the patient nourishment. If the hemorrhage is severe, but has stopped for the time being, one should operate at once, before the hemorrhage recommences.

(2) In typical stenosis of the pylorus, especially when, in the case of a long-standing ulcer, no new symptoms have occurred, and gastro-enterostomy is the operation to be chosen. Sixty per cent, of cases of stenure of the pylorus are completely cured by gastro-enterostomy, while in the cases of open ulcer gastro-enterostomy is only successful in 41 per cent, of cases. Among 134 gastro-enterostomies in ulcer of stomach and duodenum and its complication. 78 deaths occurred. Of these, eight (nearly half) occurred through con-
continued bleeding from the ulcer; therefore gastro-enterostomy is not in all cases a complete protection against continuance of the haemorrhage.

(3) Unilateral pylorus exclusion, which I did first in 1894, offers the greatest security in dealing with ulcer and its complications. It should receive special consideration if the ulcer is still fresh and causing much pain, and finally in cases of duodenal ulcer. It seems to offer the best guarantee of stopping haemorrhage and for guarding against a perforation. For ulcer situated at a distance from the pylorus, simple gastro-enterostomy is not so feasible as in cases of ulcer of the pylorus itself. This my pupil Clairmont was the first to show, on the evidence of the collected experience, that it offers more successful cases, as contrasted with 54 per cent. successful cases of pylorus ulcer. Perhaps this can be partially explained in that an ulcer, situated away from the pylorus, produces fewer symptoms than one at the pylorus, and is therefore not recognised so soon, and is not operated on till much later and in a far more advanced condition.

(5) High hydrochloric acid values of the gastric juice by distinctly favouring the development of post-operative peptic ulcer detract much from the value of gastro-enterostomy and exclusion. Whether, as it almost seems, this post-operative peptic ulcer appears more easily after pylorus exclusion is not yet certain. We have not many exclusive cases. In duodenal ulcer, when an ulcer appeared spontaneously in the small intestine, so that the small intestine already seemed predisposed to the formation of an ulcer.

(6) It has been this post-operative peptic ulcer after operations done by myself and my assistants in the hospital as well as in patients who had been operated on by other surgeons, so that the growth of such an ulcer cannot be attributed alone to our perhaps faulty technique. The ulcer of the pylorus is especially apparent in such cases where gastro-enterostomy was not strictly indicated. There are cases in which the history of the patient given by his history collector is such that the signs of gastric ulcer are wanting at the laparotomy. There may be perhaps merely a relatively small stenosis of the pylorus, some adhesions or cicatrical tissue in the stomach, In former years it was more easy to decide on gastro-enterostomy in such cases. One regarded it as a safety valve, and also a prophylactic against a stenosis occurring later, and therefore being more serious. It is certainly an advantage if it can be easily done to remove the appendix at the time any and its complications, but if the case is full of cases of duodenal ulcer, when an ulcer appeared spontaneously in the small intestine, so that the small intestine already seemed predisposed to the formation of an ulcer.

In cases when, by autopsy in vivo, I have found no other condition to indicate what one had expected to find, judging from the history of the case, and nothing to show what sort of an ulcer it was, I have done an exploratory laparotomy simply, and have refrained from doing what we may term a "concession gastro-enterostomy."

Among 15 cases of post-operative peptic ulcer of the jejunum which I have seen following gastro-enterostomies performed in my own clinic and some by other surgeons, of whom the cases of pylori were so complicated, were tried to reproduce normal conditions. Only one patient was cured, four improved, three unknown, two unrelied, five died. So we see that peptic ulcer represents a very serious complication.

(7) In cases of ulcer situated at a distance from the pylorus, as well as in cases where there is a high hydrochloric acid value, transverse resection seems to me the operation of choice, as this of all other resection, offers the best security against subsequent complications. It must be made wherever there is the least suspicion that the tumour under consideration may be of a malignant nature. Of 200 patients on whom gastro-enterostomy was performed in my clinic, and who could be kept under observation for some time after, 41 died at a later stage, from carcinoma, whilst six died with continuance of the symptoms of the ulcer and five with perforation. On the other hand, transverse resection, planned by Riedel, also advocated by Payr and Kuntner, is a relatively safe operation. We had, up to January, 1914, done twelve transverse resections, to which six cases more can be added up to July 1st, 1914, making eighteen and not a single death. I have never seen a peptic ulcer or any ulcer after this operation.

When transverse resection cannot be done, method Billroth II, should be employed. Method Billroth I is the third in order to be considered. Partial excision is to be entirely rejected.

In extreme cases only, when other operations are not feasible, jejunostomy may be considered, as it has already suggested in cases of perforated ulcer, when the patient is so weak that he must be fed immediately after the operation. Jejunostomy makes it possible for nourishment to be given even on the operation table. Further, in cases of peptic ulcer, in which for exceptional reasons complete exclusion, is the easiest and most rapid of all operations for gastric ulcers, and above all it leaves the stomach undisturbed. As it has only been done in extreme cases, one cannot wonder that it had met with so little success, and that no special complications in such cases have been associated with it. They were patients whose peritoneum had lost its power of resistance.

Now a few remarks on the Technique of the Operations under discussion.

Gastro-enterostomy in my clinic is, whenever possible, done after the method of Haecker, with Lasso postero-intestinal resection. As has been said, without any length of bowel between the stomach and jejunum. The transverse mesocolon is found, and an aperture is made in a part comparatively free from blood-vessels; through this the stomach wall is pulled forward and then secured with a Doyen clamp at a place which is as near as possible to the greater curvature. The small intestine at the junction of the duodenum with the jejunum is brought to this place, and a continuous knot of Naht; when this knot is fast, the description of the suturing. It is done in the typical way after Wölfler's method: (1) "Innere seromuscul. Naht"; (2) "Innere mucosa Naht"; (3) "Innere mucosa Naht"; (4) "Innere seromuscul. Naht"; and then four Lambert sutures applied.

It appears to me of special importance that the silt in the mesocolon should be properly sutured. In Königstein I once had an opportunity of observing a case of lues in which a mesocolon silt, made during a laparotomy, was left unsutured by my predecessor in the professorial chair. This led to an internal strangulation. Since then I have always been especially careful in suturing the silt. My successor here has agreed with this complication in a patient of my own on whom I had performed gastro-enterostomy at a period before I had learnt the importance of this suture. Finally, we had a short time ago a bad case in our clinic, where, after a gastro-enterostomy, the silt, which secured this silt to the stomach, gave way and led to an internal strangulation.

The technique of pylorus exclusion was done thus in all the cases I have mentioned: The stomach is divided between two Kocher's clamps by a Paquelin's cautery, and both proximal and distal ends are sewn up by a continuous suture while the clamps are on. After removal of the clamps, a few sutures are done "for safety." I lay very great stress on the importance of the fact that in unilateral exclusion the nerves of the stump may be severed. This happens only when they are cut through, and not when simply a band or fold of fascia is laid round.
The technique of transverse resection of stomach will be more easily understood from the picture than from a lengthy description. One is always astounded how much is gained by removal of the central portion, so that one always fears that the transverse suture will not be possible; but it is easier than one would think. It is necessary when doing this operation to supplement the longitudinal incision with a transverse incision in order to get plenty of room.

The technique of the jejunostomy is especially simple, and the method has not changed since I described it in 1889. It is simply the principle of Witzel, substituting jejuna for stomach, and I would emphasise especially this point—that the catheter should not be introduced into the intestine at any point lying higher in the abdomen than the mculo, otherwise it may lead to a kinking of the intestinal loop.

OPERATING THEATRES.

PUTNEY HOSPITAL.

ACUTE INTUSSUSCEPTION IN A YOUNG INFANT—OPERATION—RECOVERY.—Mr. Sampson Handley operated on a child, aged 7 months, who had been admitted to the Putney Hospital, and was suffering from intussusception, with vomiting, paroxysmal crying, and a passing of blood and mucus from the rectum. The symptoms had begun at 8 a.m. and she was seen by Dr. J. J. Edwards. The child did not look ill, and its crying was not distended. Dr. Edwards suspected intussusception, and deep abdomino palpation evidently caused some pain, but no definite swelling could be felt owing to the resistance of the recti muscles. The following morning Dr. Edwards brought the child up to the Putney Hospital where an anesthetic was administered. A definite sausage-shaped mass could then be felt in the hypo-gastrum. Rectal examination disclosed no tumour, but blood and mucus were present on the examining finger.

Fourteen hours after the onset of symptoms Mr. Handley opened the abdomen in the middle line. A large intussusception was found occupying the situation of the transverse and the descending colon. The intussusception was very much congested and blue, and reduction was effected with great difficulty, the peritoneal coat of the large gut cracking in many places during the process. The intussusception, which included the appendix, was greatly swollen and congested and infiltrated everywhere with effused blood. The mesentery of the ascending colon seemed to be deficient and the cecum was very long.

Bezoars were not at all obvious as predisposing causes of the intussusception, Mr. Handley anchored the ascending colon and excised the peritoneum of the right iliac fossa by two fine silk sutures. The peritoneum was then closed with fine catgut, and the abdominal wall with figure-of-eight fishing gut stitches.

The operation occupied about 20 minutes. Mr. Handley said that the principal interest of the case lay in the extreme youth of the patient. Children so young do not stand abdominal operations well. It was very important, he pointed out, that the operation should be done quickly, and that the surgeon should be as gentle as possible in his manipulations during the operation, as it was very important to avoid still, and if possible, the reduction of the intussusception should be carried out without delivering it from the abdomen. There seemed to be no doubt, he remarked, that the principal factor in the case was the disposing cause not only of volvulus but of intussusception as well.

The following day, after a simple enema, flatus was passed, and a large quantity of blood mixed with blood. About thirty hours after the operation the child vomited large quantities of greenish fluid of offensive odour, but not definitively faeces, and the abdomen was distended. Collapse appeared imminent. Dr. Newman administered 5 minims of pituitary extract. An hour later the little patient was practically pulseless and appeared in a desperate condition. Hot fomentations were ordered to the abdomen. The following morning the condition had greatly improved and the bullet was said to have been expelled. Subsequently the child made good progress and left the hospital sixteen days after admission.

SPECIAL REPORTS.

THE EIGHTY-SECOND ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT ABERDEEN, 1914.

[By Our Special Representative.]

CONCLUDING ADDRESS.

THE ANNUAL EXHIBITION.

Despite the fact that most of the exhibitors held duplicate displays in London and Aberdeen, owing to the clashing of the two Congresses, there was, nevertheless, a very good show of medical books, appliances, instruments, foods and drugs. The exhibition was conveniently housed in two spacious rooms already well-known to the members of the various sections. Messrs. Burroughs Wellcome and Co. were well to the front, and in an elegant display were to be seen their well-known specialties, including "Tabloid and Solod" products, and the very elegantly-decorated polemic medicaments. Among their recent preparations was to be seen "Laxamol," a refined paraffin jelly of service in chronic constipation. Messrs. Cadbury Bros., Ltd., were showing their high-class preparations of cocoa and chocolate. Among the attractive exhibits at the stall of Messrs. John Wright and Sons, Ltd., of Bristol, were to be seen "The British Journal of Surgery," "The Medical Annual," and the two valuable books on the treatment of "Differential Diagnosis of Main Symptoms" and "An Index of Treatment," by Drs. Herbert French and Robert Hutchison respectively. The Regal Syndicate, Ltd., showed their ingenious combination of agar-agar with cascaria sagrada. Messrs. Ingram and Royle, Ltd., presented for inspection specimens of the famous waters of Carlsbad, Giesshuber, Vichy, etc. At the stall of Messrs. Zimmer and Co., Ltd., were exhibited, among others, Messrs. Hamilton Pegler’s "New Map Scheme of the Symptoms and Distribution of the Fifth Nerve (Trigeminus) with its Ganglia and Connections;" Dr. Harrower’s "Practical Hormone Therapy;" and "Prof. De Quervain’s "Clinical Surgical Diagnosis;" The Charles H. Phillips Chemical Co., were well in evidence with their milk of magnesia, phospho-muriate of quinine, and digestible cocoa. Of the preparations exhibited by the Saccharin Corporation, Ltd., novocain, trinalin, a harmless substitute for morphia, and phytin (eial), a natural phosphorus salt, commanded attention. The well-known "Ranuk" polishes, stains and stoppings were to be seen at an attractive stall. Messrs. Brand and Co., Ltd., were showing their own well-ground meat essences and lozenges, as well as "Ferrocrinis," a pleasantly flavoured preparation of iron and meat-juice. The Horlick’s Malted Milk Co. exhibited their valuable food, both in powder and tablet form, and in addition to their usual advantages for morphia and phytin (eial) were demonstrated to interested inquirers. At the stall of the Bayer Co., Ltd., were a large number of pharmaceutical specialties, prominent among which were "Adalin," a salicylic hypnolac; "Istin," a synthetic lacto-"Polystrool," a scientific galactogogue; and "Cymarin," a cardiac tonic and diuretic, in addition to the three somatose preparations. Some useful voice pastilles were exhibited by Messrs. Meggisson and Co., Ltd., as well as "Vocalzone" solution and gargle for use in tonsilitis, nasal catarrh, pharyngitis, etc. At the stall of Messrs. D.
Appleton and Co. were to be seen many interesting medical works, among which may be mentioned a new edition of Dr. Essex Wynter's "Minor Medicine," Dr. W. Gilman Thompson's "Occupational Diseases," and J. R. H. Reves's book "Pneumonia in its Microscopic Aspects." H. K. Lewis presented a large number of important medical books, among which were to be seen Dr. C. K. Millard's "The Vaccination Question in the Light of Modern Experience," a second edition of Dr. Lewis Jordan's "Heredity," and a much-admired "Mechanico-therapeutics in General Practice." Lemo and Oxo were well to the front with their high-class nutritive preparations. Among the exhibits of the Nestlé and Angell were of especial interest. A brand of cheese particularly pure "Milk Maid Brand of Pure Rich Thick Cream," free from preservatives. The Apollinaris Co., Ltd., had samples of Apenta, Eddowes, and Johannis waters and table beverages. A number of well-known medical books were on view at the stand of Messrs. W. B. Saunders Co., including Dr. Crile's work on "Ano-association," Sir Berkeley Mylnihan's "Abdominal Operations," a new edition (11th) of Anders' "Practice of Medicine," and Dr. Ray's "Opera-1." The well-known hygroscopic and antiseptic application "Antipilostigmine" was much in evidence at the stand of the Denver Chemical Manufacturing Co. The various preparations and adaptations of "Calcium" were demonstrated by J. E. R. McDonagh. Dr. M. C. W. Young showed a preparation illustrating the derivation of a coccus resulting from heating the B. anthracis. Some interesting photographs were shown by Dr. D. B. Barlow of cases of yaws and of specimens of wax casts, colour photographs and drawings of rare dermatological conditions were exhibited by Drs. Norman Walker, Alfred Eddey, and Haldin Davis. X-ray pictures, pathological specimens, and one of a case of scabies were exhibited, attracted much attention.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

AUSTRIA.
Vienna, Aug. 2nd, 1914.

DYSTONIA MUSCULORUM DEFORMANS.

At the recent meeting of the Gesellschaft für Innere Medizin and Kinderheilkunde, Dr. B. Bischof exhibited a case of dystonia musculorum deformans (progressive torsion-spasm, Ziehen-Oppenheim Disease). The history of the case dated from an insidious commencement of five years ago, from which it had gradually evolved, and for the past three years had manifested itself in the form of pains in the feet, which were accompanied with a sensation of dragging weight. There were also stabbing pains in the back. When the patient assumed the erect posture, the right lower extremity always displayed a position of torsion, the foot presented a characteristically club-foot, while the spasmodic condition of the spinal musculature produced the distortions of lordosis and scoliosis. The spasm subsided when the patient made a controlling effort, or when he was supported, or assumed a position of repose. The small muscles of the feet are in an atrophic condition. The neck is held in a position of slight backward inclination, as a result of which the muscles of the cervical region stand out in a state of strong tension. Slight twitches are observable in the muscular system. The patient now walks only with extreme difficulty. The atrophy of his left arm is due to the muscular spasm and organic change of the central nervous system. Is this one of the cerebellum, or of the nerve-paths leading therefrom?

NASSO-PHARYNGEAL TUMOUR WITH CEREBRO-SPINAL METASTASES.

Dr. A. Finzi demonstrated the case of a male patient, aged 22, who presented a nasso-pharyngeal tumour which had proceeded to metastatic developments in the base of the brain and in the spinal cord. Two years ago, 'a tumour had formed in the neck, and a quantity of pus un mixed with blood was removed therefrom by operation. Paroxysmal radiating pains subsequently appeared, especially in the form of left-sided cephalalgia. Large lymphatic swellings gradually developed in the neck, and the olfactory and auditory sensations had become more obuse on the left side. On application of the radium treatment some improvement was manifested, but this did not continue long. The patient now suffered from acute left-sided cephalalgia, left occipital pains radiating from the vertebral column. There was also paresis on the left side, which was accompanied with a slight degree of exophthalmos, of which condition a slight occurrence was described. There was also a slight paresis of the left arm. There was analgesia which extended over the left half of the face, marked lowering of the olfactory and gustatory sensibility on the left side, a slight degree of paralysis of the left lateral half of the velum pendulum palati, and the presence of a hyperaesthetic zone at the level of the fifth and sixth dorsal vertebrae, which was also the seat of radiating pains. A sarcomatous tumour occupied the nasso-pharyngeal space; this grew from the wall of the epi-pharynx, and its surface had become partially ulcerated. Metastatic tumour of the cervical lymphatic glands had developed, and had also apparently formed in the middle fossa of the base of the skull and in the structures of the vertebral column.

TREATMENT OF TRACHOMA WITH ULTRA- VIOLET RAYS.

Dr. F. Rössler has just published his experiences of the Finser ray, temperature treatment of trachoma, accompanied with the formation of small "sago-grain" nodules in the tarsus and fornix, or with papular hypertrophy and the development of numerous secretory formations. The effectiveness of the Finser rays has been found by him to yield the best results of any, and in the minimum interval of time. In the other stages, "blue-stone" had been found to prove the best local application. In cases which had reached the stage of panus formation, any application of the Finser-rays was contra-indicated.

USE OF ARTHION IN IRITIS.

Dr. H. Krebich has published a paper which gives his experiences of the use of Bruck's arthion, administered by way of intra-venous injection, in cases of gonorrhoeal iritis. The indications of use of arthion had found that it gave surprisingly favourable results, and was absolutely without danger.

THE ETIOLOGY OF ULCUS VENTRICULI.

A great deal of interest is now directed here to the recently published theory of the genesis of ulcus ventriculi which has been formulated by Dr. H. Sieben (Basel). Dr. Sieben has based his researches on this much-debated question. He has arrived at the conclusion that such conditions as cause an increased formation and frequent regurgitation of the intestinal contents into the cavity of the stomach can always be guaranteed to produce typical specimens of ulcer ventriculi. This fact he has proved by carefully repeated experiments. He had found that after ligature of the pancreatic duct, when the most unfavourable conditions were created for the unrestricted action of the intestinal ferments on the lining membrane of the stomach, no ulcerative process
CORRESPONDENCE.  

was ever found to develop. On the other hand, feeding with trypsin was always found to be followed by the appearance of typical ulcers. Accordingly, the conclusion becomes unavoidable that, in the experiments on the cat, the formation of an ulcerous membrane was no other than the trypsin which functioned, so to speak, as a foreign body in the cavity of the stomach. It has also been found, besides dealing with the formation of an ulcus tyrannum—and under conditions of which the development in the human organism is quite readily conceivable.

**UNITED STATES OF AMERICA.**

**New York, Aug. 5th, 1914.**

**THe ILICIT CONSUMPTION OF OPIUM AND OTHER NARCOTICS IN THE UNITED STATES OF AMERICA: ITS RELATION TO THE GROWTH OF AND TRAFFIC IN OPIUM IN THE ORIENT.**

It is the large Chinese population in America which has impelled the United States Government to inquire into and endeavour to regulate the consumption of opium by unauthorised persons. In the course of this inquiry, it became manifest that far more opium was being imported than could be accounted for by what the Chinese knew, and which they presumed to be legal. At the same time, it became generally known that the number of secret takers of drugs was becoming very large, and that a large proportion of these were takers of derivatives of opium. A little later, the researches of the Chinese authority on the Acupuncture, which has reached an extent to menace the health of the nation to an even greater degree than has been the case in China. It will surprise these unacquainted with the fact to learn that one hundred and fifty thousand pounds of crude opium for smoking were imported in one year. The manufacture of this was permitted on payment of the nominal license of ten dollars per annum. The total amount of opium accounted for by the United States is found to be one hundred and fifty thousand pounds. In addition to this, a considerable amount is smuggled, especially since the prohibition of the importation of smoking opium.

Customs returns since 1860 show that about 25 per cent. of the imports of opium is used for smoking. Deducting this proportion from the amount entered at the Customs Office, the following results of imported opium are revealed—a Decade 1850-1860, from 358,194 lbs. of crude opium to 741,663 lbs., being an increase of 111 per cent., the increase of population only being 34 per cent. A large amount of opium was, besides, used for medicinal purposes, and this is estimated at about 20 per cent. additional to that entered at the Custom House. In the following five years occurred the civil war; and a great deal of opium was believed to have entered the United States on account of the war. In the Customs returns show an increase of only 48.5 per cent., with a population increase of 22 per cent. It must be remembered, too, that the medical demands were greatly increased by the war.

For the decade 1870-1879, the importation was 1,020,023 lbs. as against 1,103,041 lbs. for the preceding decade, being an increase of 74 per cent., while the population only paid duty for a part of the time, and was imported in enormous quantities to anticipate the Dingley tariff. Hence in the following decade ending 1890 the importation was 2,500,000 lbs., and the population 1,926,023, 4,800,088 lbs., while the population increased 15.9 per cent.

Taking the whole period from 1866, we find that there is an increase of 341 per cent. in the amount of opium imported in the last decade, against an increase of population of 133 per cent.

This increased amount is by no means due to the increase of Chinese in the United States. Thus, in 1866, the Chinese population of the United States was only 188,000. From a survey of the Chinese quarters in the largest cities it has been estimated that 35 per cent. of these people smoke opium. These may be divided into heavy smokers, who use six pounds per annum; these number about ten per cent.; light smokers, who use 1½ lbs. per annum, who number about 15 per cent.; and social smokers, who use about one oz. per annum, to a number of 10 per cent.

From these figures we can calculate a total Chinese consumption of 90,750 lbs. As the average importation is 145,168 lbs., if we calculate the importation of smoking opium as about 25 per cent. of the total importation, this amount, when converted into units to be accounted for by non-Chinese smokers. It is true that the foregoing statistic does not agree with that submitted by the United States to the International Opium Commission at Shanghai; but since that estimate was made further data have been derived from the Japanese inquiry in Formosa, from figures submitted by the Chinese members of the Commission, and by the investigations of the United States delegates in the Far East. In that dependency, it is believed that Chinese opium is smuggled, that 32 per cent. of Chinese male adults smoke opium.

But on the other hand there must be added to this $8,418 at least 20,000 lbs., which is smuggled into the United States from Canada, besides what is surreptitiously manufactured in the United States.

The Hon. Mackenzie King, now the Minister of Labour for Canada, reported that there were at least seven factories manufacturing smoking opium in the Pacific Coast Cities of Canada. In 1907 their receipts were over $600,000. The owners of these are Chinese, who import the crude drug from China and manufacture it, and the whole is entirely consumed in Canada itself. Mr. King concludes that much of it is smuggled into the United States, and this opinion is confirmed by the American Customs collectors, who find it impossible to prevent the smuggling, and estimate that 20,000 lbs. a year crosses the border.

It is difficult to estimate, however, the number of American opium smokers, for the practice is generally not considered worth while. It is calculated that about 10,000 are regular smokers, who are able to smoke only when they have money and are not in gaol. Thus, the consumption per caput is smaller than that of the heavy-smoking Chinamen. Nevertheless, as the United States is a land of doctors, physicians, and intelligent opium smoking Chinamen, it is computed that in New York, Chicago, and San Francisco, there are between 5,000 and 15,000 Caucasian and negro smokers of opium. Taking 7,000 as a fair average. From the foregoing figures, it is seen that this figure represents a large number of the population, it might be estimated that there are 150,000 white and black opium smokers. This would correspond to a consumption of about half a pound per annum for each. Of the assumption that 68,000 lbs. are consumed, in accordance with the foregoing calculation.

The danger has been long realised; it has not only permeated popular literature, but both States and municipalities have legislated against the evil. Efforts
LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE WAR AND THE NEWSPAPERS.
To the Editor of The Medical Press and Circular.
Sir,—It was impossible without sympathy to read your frank statement, with regard to the totally undeserved injury which medical papers must sustain through the indirect effects of the truly terrible struggle which the whole Empire has entered upon, and no less stiffening to view the attitude of the great bulk of leading papers. These papers set the fashion to the mass of inferior fry. They follow what is called "commercialism," and their newspaper is a struggle to amass money by any means that does not include felony, although there are some professional guardians of the public welfare who do not stick at felony when they have made themselves tolerably sure that when put into the dock finally for trial a flaw will be found in the indictment. Then they will be heroes to their pals and sure of a biography after their deaths.

To-day being the Sabbath, it is truly edifying to notice the shreds of advertisements, of whose character the proprietors and managers are men who are forth in special Sunday editions to deceive and injure our soldiers—those gallant men about whom the papers write in blasphemous terms. I send you some sheets from Forrest papers of the day. It would not be better to give eloquent appeals to the Almighty to guard our noble soldiers, instead of assisting to exploit and injure them by the publication of advertisements of these fraudulent quack medicines.

I am, Sir, yours truly,

Scribner.

Sunday, August 16th, 1914.

INFANT MORTALITY.
To the Editor of The Medical Press and Circular.
Sir,—At this time of year infant mortality among infants is always high, and since it is to the young generation that the country must eventually look for its strength, it is of the utmost importance at this juncture to prevent all unnecessary waste of life. At an emergency meeting of the Executive Committee of the Association of Infant Consultations and Schools for Mothers, which has just been held, it was decided to ask the co-operation of the press to point out to all those who have charge of young life the danger of deaths and much illness may be prevented by the observance of a few quite simple principles of mothercraft, of which the most important are:

1. To persevere with natural feeding up to the end of the ninth month; even if supplementary feeding by night is not possible, the mother is compelled to go out to work. Employers of female labour are earnestly requested to give nursing mothers opportunities for feeding their babies.

2. That in those cases in which such opportunities are impossible weaning is by no means necessary. A supplementary feeding of cow's milk will not disagree with the infant and may save the infant's life.

3. That the chief causes of illness among nurses and other babies is irregular and too frequent feeding by day as well as by night: intervals by day should not be less than three hours, and at night a long interval of some six-eight hours should always be provided.

4. Expectant mothers should also seek advice as to their own health, either by consulting their doctors or by attending at schools for mothers.

5. That stimulants are not only unnecessary, but are harmful both to nursing and expectant mothers.

Yours, etc.,

ERIC PRITCHARD, M.A., M.D.Oxon.,
Chairman of the Association of Infant Consultations and Schools for Mothers.

ELEANOR Ritchie, M.D., Secretary of the Association of Infant Consultations and Schools for Mothers.

4 Tavistock Square, London, W.C.,
August 15th 1914.
OBITUARY.

DE W. H. CARTHEW DAVEY, LIVERPOOL.

We greatly regret to have to announce the death of Dr. William Henry Carthew Davey, of 50 Princes Road, Liverpool. Deceased some years ago, from some accident sustained in an electric furnace which had a fatal termination on the 11th inst. Before his illness he was the fullest health and bustling in work. The announcement of his death will come as a great and painful surprise to his numerous circle of friends and admirers. Dr. Davey was born in London in 1867, studied at Charing Cross Hospital, where he afterwards held an appointment as House Surgeon. Later he obtained the appointment as House Surgeon of the Royal Northern Hospital, Liverpool, and upon relinquishing this he was appointed Surgical Tutor at the Hospital and settled in practice in a central part of that city, where he soon succeeded in establishing an extensive and lucrative practice. He held several public appointments, amongst which were the Surgeoncy to the Liverpool Orphanage, Myrtle Street, the Agency to the Admiralty, as also the medical referee to one of the largest insurance companies in the year 1899. He married—Sara, daughter of the late Robert Thomson, of Belfast, J.P., by whom he is survived. Two children, both of whom are boys, are also left to mourn his loss at a period of life when their parents' care and advice were of untold value. He was a member of a number of learned societies, amongst which may be named the Liverpool Medical Institution, and a firm supporter and contributor to this Journal. His funeral (by cremation) took place on Friday last, the 11th inst.

DR. J. FLETCHER LITTLE.

We regret to announce the death of Dr. John Fletcher Little, which took place at 33 Dorset Square, N.W., on the 9th inst., aged 71. The deceased, who qualified as L.R.C.P. and S.Edin. and L.M. in 1866, received his medical education in Dublin, Liverpool, Charing Cross Hospital, and the University of Dorpat, in which he became M.B. in 1888. He was elected M.R.C.P. Lond. in 1889. Dr. Little was well known in Marylebone, and he had served on the London County Council. He was also Medical Officer of Health for Harrow. He was a Vice-President of the Medical Graduates' College and Polytechnic, and was formerly Physician to Mount Vernon Hospital for Consumption, the London Temperance Hospital, the West End Dispensary, and Marylebone General Dispensary. He had previously held the appointment of Physician to the Ben Khwidd Establishment and the Liverpool Convalescent Institution. Dr. Little had contributed many articles to medical journals, including articles on "Massage and Mechanico-Therapeutics" to the Index of Treatment. He was also the author of a work on "Rheumatoid Arthritis."

REVIEWS OF BOOKS.

TWO YEAR-BOOKS.

One of the main objects of the reviewing of books is to call the attention of readers to those that are worth purchase and perusal, and, on the other hand, to warn against, just as the case may be. For this point of view there is little need to write a review of Messrs. Wright's "Medical Annual." (a) for, every medical man who reads at all must know that it is indispensable. Each successive issue makes its wonder more and more, so that it is not out of place to include in the review at all, in fact, anything that has appeared in this series, in order to give the public a digest of what has been done in the year. The most remarkable feature of this work is its completeness and thoroughness. It is a compilation of all the important communications of the year dealing with those subjects as the cause of death under chloroform, intractable anæsthesia, spinal anæsthesia, and anæsthesia associated with "cancer," Mr. Monsarrat quotes, with illustrations, some valuable and insuperably known work of Dr. T. F. Paul on the history of epiphrenonema and its relation to degrees of malignancy, and on "Vaccines" contained in the "Review of Therapeutic Progress" by Dr. F. J. Charteris, and is hardly sufficient, in view of the rapid development of that method of treatment. In particular, we might expect nothing more from the "Medical Annual," so far as a supplement to Messrs. Wright's current medical knowledge, Dr. Priestley supplies a useful article on "Public Health," in which he quotes the most important legal decisions of the year. The weakest feature in the present volume, as in its predecessor, is the gloom, with which the annual abounds, because, as a whole, it is all very good, it would be ungenerous to dwell on the few weak points.

The "Tuberculosis Year Book" (b) edited by Dr. Kelynnack, contains no book of useful information of all to whom are concerned in tuberculosis work. It caters for the clinician as well as for the administrator, and indeed, also for members of public boards who have to formulate and carry out tuberculosis schemes. Contributions from writers who can speak with authority we may mention specially the article by Sir Thomas Oliver on "Occupation and Tuberculosis," and that by Dr. Nathan Raw on "Bovine Tuberculosis." Those engaged in the work in tuberculous sanatoria, which, as a one-third of the book, does not appear to us to be specially useful. The volume is of cumbersome shape and is too heavy for comfort, but, as we have said, it contains considerable matter of interest.

PSYCHOLOGY AND BIO-CHEMISTRY.

The "Vorwort" of this extremely interesting and suggestive booklet is dated from St. Petersburg: May last year. That of the Russian issue bears the date December, 1911. The text is in German. "Vorwort" is editor's congratulatory course of lectures at his University. The booklet presents a well-thought-out presentation of our current knowledge of the indented bordering margin which limits and connects the respective domains of biological chemistry and psychological psychology. The transition to the great mass of enlightening (and sometimes confusing) matters of fact and opinion which the tidal wave of nineteenth century materialism set in centrifugal motion all round the world of thought. The spirit of research that was set in motion by the epoch-making synthesis of urea, which "dynamited" the barrier that had previously marked off the respective domains of organic and inorganic matter through all the centuries, encouraged a large section of enthusiastic, but sometimes also juticious, apathetical, and scientistic research and scientistic infallibility to hope for the early attainment of what has hitherto proved to be unattainable. So did the invention of the colossal "man's nest of the "Origin of Species by means of Natural Selection." But each explosive movement had unquestionably the very desirable effect of stimulating and encouraging research in every department of its special domain of knowledge, and thus furnishing an enormous collection of utilisable facts, and suggesting the book.

(a) "The Medical Annual; A Year-book of Treatment and Practitioners' Index." By various contributors. 1914 and 1915. Price £1 1s. net.

tive" subjects of thought and criticism. The dangers of
vulture hunting have been as clearly illustrated in
connection with those movements of intellectual in-
volution which have repeatedly checked the upward
ward progress of the human brain. The present
human, however, a weaknesses which may well be held
to merit a substantial share of sympathy. And
although the mass of collected facts hitherto garnered
in each special compartment will not convey to the
logical mind the persuasive power of the methods of
demonstrative proof— even when most skilfully
manipulated— every earnest inquirer has the fullest reasons
for gratitude to those who have done so much to plug
out the heart of the mystery of Nature's laws and
methods of movement, which now and then are very
partially screened off from the mental vision of those
who have eyes to see.

The great object of Dr. Justschzenko has been to
demonstrate and illustrate the mutual connection and
inter-dependence of mind and matter in the human
organism, to the present knowledge of which so vast an
amount of material has of recent years been contributed
by researches in the very interesting department of
biochemistry. Its facts are far too numerous to be even
 glanced at in any detail. We will just give for sake of
classification the list of the neurin, kreatin, neutrin, lysatin,
lysoxylein, methylguanidin; (2) santhin group (santhin,
lysoxylein, methylguanidin); (3) xanthin group (xanthin,
hyperoxanthin, adenosin, xanthinoluen, xanthinourea,
adenosinourea, with open chains (methylamin, trimethylamin,
neutridin); (5) amino-acids (glycocol, leucin, etc.); (6)
leucamines of unknown chemical constitution, such as plasmin
and spermin. Perhaps a good test of the reader's enthusiasm would be afforded by the degree of his
deliverance from this chain of investigation at its present
limit, and try to add a few more links to its crescent
longitude (7).

LECTURES ON DIETETICS. (d)
The series of lectures which comprise this volume
were delivered at the New York Post-graduate Medical
School, and the author is to be heartily congratulated in
now publishing them in book form. The subject of
dietetics has been so long the happy hunting-ground of
false authors and quacks. The book is based on sound reasoning and possesses much
practical utility.

After discussing the principles of diet and nutrition, the author deals with the digestibility of foods and
the dietary discretion of acute and chronic diseases of prolonged duration and in chronic
diseases and the diet in chronic affections of the digestive
tract next receive consideration. There are chapters on the dietetic treatment of chronic diarrhoea and the dietetic treatment of diabetes mellitus. Various
diet regimens are examined and the author concludes
with a chapter on indications for and description of the
method of diuretic feeding. It will thus be evident that much ground has been
covered in this small volume and the fact that this book is used by medical students and practitioners of the actual lectures makes its perusal all the more interesting, and enhances
its practical value. There can be no doubt that this monograph will facilitate the question of diet to the
practitioner, and will aid him in its management and
we can with confidence recommend it to our readers.

THE PRACTICE OF MEDICINE. (b)
This popular text-book having reached its tenth
edition has been very thoroughly revised, and many
sections have been recast, a notable example being the
appearance of a separate section on the glandless glands. Intuitive pathology, owing to the
researches of modern pathology, has been transferred
from the chapter on nervous, to that on infectious
diseases. The modern work on diseases of the heart has also been largely recast, and very
notable skin diseases have been added. Useful skew diagrams have been obtained from Dr. A. C. Jordan.
We do not doubt that students of the present day will appreciate this text-book as much as did their predecessors the previous editions.

MANUAL ON MASSAGE TREATMENT. (a)
The fourth edition of this useful book has just appeared in revised and enlarged form, with a chapter on
massage of the eye by Dr. A. Darier, of Paris. The first edition appeared in 1889, and so far as we
know, was the first book in English on this subject. The present volume is highly to be recommended to
the physician and surgeon alike as well as to the specialist and general practitioner as a useful text-
book and reference manual at one and the same time.

In our estimation, the British Isles, massage has by
no means reached the highest pitch of development,
for there are still large numbers of medical men who have no practical acquaintance with the methods of
application of this most useful remedial agent, and who
are unable to give practical reasons for how it should be carried out, but are content to rely upon the skill and discretion of the manipulator
whom they employ. If the latter has had a sufficient
training, little or no harm will ever be done, but for
success in treatment we still look forward to the day
when the British physician will no longer consider it beneath his dignity either to possess an accurate
theoretical knowledge of the subject, or, as on the Continent and in other places abroad, be his own
massuer. A brief résumé is impossible since the
text is very extensive. We most
cordially recommend it to medical men and students of
massage as one of the best standard works to which
they can refer.

HANDBOOK ON SANITATION. (b)
This manual of theoretical and practical sanitation is
primarily intended for sanitary inspectors and other
inspectors engaged in public health work. It is
divided into three parts: I. Sanitary Science; II.
Sanitary Practice; III. Sanitary Inspection. The
questions discussed are similar to those dealt with in
any manual on practical sanitation and need not be
detailed. The book is pleasantly written and the
author has acquired the art of marshalling his facts in
an interesting manner. The work is of course based
largely on sanitary practice as carried out in the United
States, which differs in several respects from that of
in this country. One very marked difference in this
respect may be mentioned. In this country it is
usually considered sufficient for a public water supply
to be rendered supply by the addition of chlorine to
distribution, but the author maintains that whether
this has been done or not there ought to be in every
house some means of further purifying the water.
The illustrations, though not very numerous, have been

(a) "Massage Manual of Treatment." By —. Graham.

(b) "Handbook of Sanitation." By —. Price, M.D.,
Director of Investigation, New York State Factory Commission, et al. Third
Hall, Limited, 1913. Price 65. (2d ed.)
judiciously selected and are extremely good. We have no doubt the book will have a wide circulation in the United States, and we can recommend to those engaged in public health work in this country as a useful adjunct to more standard works.

**TUBERCULIN TREATMENT. (a)**

No better test could be made of the value of tuberculin than in the case of sanatorium patients, seeing that they remain long enough under treatment and observation to determine the success of the treatment. Dr. Bardsley's report is, therefore, one which will be studied with interest by the profession, as the present time is critical, and decisions are being made as to the value of tuberculin. While too short a time has elapsed to give anything like a definite pronouncement on the subject, Dr. Bardsley's words must carry a certain amount of weight. He says that "tuberculin has not proved itself to be a remedy in the ordinary sense of the term, and no immediate or striking results are to be expected from it, even in the most favourable cases." He points out, moreover, that in a certain number of cases, tuberculin therapy has been followed by a relapse, and that "experience up to the present time shows that the administration of tuberculin is quite unsuitable as a routine method of treatment for all cases of pulmonary tuberculosis, and that its indiscriminate and careless use may have a very serious effect upon the health of the patient."

May these words sink deep into the minds of those who to-day are forward in advocating tuberculin treatment! This is a most excellent report, and we sincerely trust it will have a wide circulation.

**POCKET MEDICAL DICTIONARY. (b)**

This concise book in its new edition has been carefully revised and includes much new material. Many of the new terms which have been included from the different departments of medicine have been added, thus adding a few more pages than the previous edition and making it more complete. The Editor has made no attempt in this volume to replace the larger dictionaries, which are necessary to a thorough understanding of the language of medicine, but has made an effort to extend the possibilities of a pocket medical dictionary beyond that hitherto attempted.

The vocabulary is strictly up to date, the definitions of terms are concise and precise, and the additional space has been used to advantage. The order of arrangement is strictly alphabetical, and in addition, it also contains a considerable amount of matter in tabular form, which serves to group correlated facts, and is a valuable aid to the memory and quick consultation.

**THE DIETETIC TREATMENT OF DIABETES. (c)**

The pathology of diabetes, if not fairly definable as a *terra incognita* in our enlightened twentieth century, as it admittedly continued to be during all the preceding ages, still remains unmapped to any degree approaching the standard of precision which may now be proved useful in the provision of the successful therapeutic code which is destined to lead to the physical salvation of the afflicted. Indeed, the accuracy of the author of the booklet now before us will be challenged by few practising members of our profession, when he states that throughout the researches of physiologists, pathologists and physicans in modern times, the etiology and pathology of this ill disease remain as obscure to-day as they were in the days of Charaka and Susruta. Thus, in the interest of the disease may be said to present itself through the respective reflection of each of two of its facets—"the historical and the clinical. And, as our author has evidently devoted earnest care and studious observation to the attempted mastery of this chosen task, his views on the subject of an interesting clinical example which, if continued to be one of the most vexatious and unmanageable of that inextricable series, should receive a full hearing from all physicians. It is interesting to read that: "... hindu physician of yore were, perhaps, the first in the world to diagnose diabetes"—and it is decidedly instructive to learn that "... kidney disease is not so common amongst Indians as amongst Europeans. This is due to Indians being accustomed to the vegetarian diet, which is non-stimulating, and also to their eschewing alcoholic beverages." Every medical practitioner should test the results here claimed for "the coconut cure."

**RENAI. DIAGNOSIS. (a)**

The advances made in urology are very largely due to increased facilities for making accurate diagnoses. These modern methods are here fully set forth. The author first discusses the physiology of the renal functions, and then goes on to speak of the competency of the present diagnostic methods. He is critical, but definitely reasonable. He next refers to cryocopy and the various functional tests used in diagnosing renal affections. Finally, he deals with the significance of functional diagnosis in the medical and surgical treatment of kidney disease, and the remainder of the book is devoted to interesting clinical examples. The book is one of considerable importance, not only to the specialist, but also to the general practitioner. It is a work of quite exceptional merit, and we are pleased to find that an English translation now exists. The translator's part has been well done, and the English rendering is quite readable and, so far as we can judge, is accurate and faithful to the original. As a handy epitome of modern methods of renal diagnosis, we can strongly recommend it.

**ORGANIC CHEMISTRY. (b)**

This is a very good book, full of solid information and liberally bestowed with graphic formulas. For the student who early feels the attraction of organic chemistry the work is ideal, but for the ordinary student, especially those intended for medicine, he could have no more easily read book. In this subject, space devoted to chaining the attention by the mention of some practical application is never wasted, it minimises the strain of the lesson and allows the memorising of a fact to be easily accomplished without effort. That the book is characterised by a mass of interesting clinical examples. The book is one of considerable importance, not only to the specialist, but also to the general practitioner. It is a work of quite exceptional merit, and we are pleased to find that an English translation now exists. The translator's part has been well done, and the English rendering is quite readable and, so far as we can judge, is accurate and faithful to the original. As a handy epitome of modern methods of renal diagnosis, we can strongly recommend it.

**APPLIED SPECTRUM ANALYSIS. (c)**

This scholarly work of the late Dr. Macmunn, owes its publication to the devotion of Mrs. Macmunn and three of her late husband's friends. To those who have already mastered the elementary technique of spectroscopy, this book will prove most useful, written as it is by a master of art. That the book is characterised by a mass of interesting clinical examples. The book is one of considerable importance, not only to the specialist, but also to the general practitioner. It is a work of quite exceptional merit, and we are pleased to find that an English translation now exists. The translator's part has been well done, and the English rendering is quite readable and, so far as we can judge, is accurate and faithful to the original. As a handy epitome of modern methods of renal diagnosis, we can strongly recommend it.
botanist will find not only accurate and important information, but food for reflection as well. In the preface Professor Gamble refers to two previous works of Dr. MacMunn as “authoritative expositions.” The one under consideration is certain to be similarly accepted.

**LITERARY NOTES.**

The reprint by Messrs. John Wright and Sons, Limited, of the second edition, revised and enlarged, of Lieut.-Colonel P. C. Gabbett’s “Manual for Women’s Voluntary Aid Detachments” is opportune at the present moment, especially as so many ladies are anxious to do their bit in bearing to the sick and wounded in warfare. This useful little book does not deal with first aid, a knowledge of which is presupposed by its readers, but rather indicates the direction in which women’s detachments may turn their thoughts. It contains notes on nursing and diet, the preparation for emergency operations, list of equipment required for a temporary hospital, training and field drill. The last chapter deals with the question of how and where to train to become a qualified member of a W.V.A.D. The price of the book is 1s. net.

* * *

“The Year Book of Radiology for 1915” is announced by Messrs. Longmans, Green, and Co. as in preparation, edited by Robert Knox, M.D., and James H. Gardiner, F.C.S. The object of the work is to give an account of the most recent advances in our knowledge of radium, X-rays, and the allied phenomena, both from the medical and the physical point of view. The volume will comprise a series of authoritative articles by specialists working in radiology, and a directory of qualified medical men practising in radium, X-rays, radium and electro-therapeutics, both at home and abroad, also a list of hospitals and institutions where such treatment is carried out.

Our contemporary, The Medical Officer, has issued a leaflet on “The Best Foods to Buy during the War.” It is compiled from publications of the Croydon Health Department, the National League for Physical Education, and the National Food Reform Association. A moderately complete list of flesh, fish and vegetable foods is given, and their nutritive values and low market prices stated as a guide to poor people and all others who desire to economise during the present crisis. The advice is based on the preparation of some cheap and nourishing dishes, all of which appear to be framed on sound lines, and will, if followed, prove of value to those for whom it is devised. The leaflet is being supplied to Public Health Authorities for distribution.

* * *

The twentieth series of “Quiet Stories” from Truth, like its predecessors, furnishes suitable reading for the railway carriage or the waiting-room. The stories are, as usual, entertaining, though perhaps the element of unexpectedness is not as marked as in previous years. Most of the writers make no pretence to literary style, but even complete lack of pretence does not prevent a certain infinity to the stories. The stories of the supernatural are among the best, and it is a tribute to the power with which “Lady Magpie’s Leap” is written to say that even reading it in a railway train, it gave us a creepy feeling.

**MEDICAL NEWS IN BRIEF.**

Plague at Hon-Kong.

The Secretary of State for the Colonies received on Monday last telegraphic information from the Governor of Hong-Kong that five cases of plague had recently occurred during the week, and that there had been five deaths, Gift of a Convalescent Home to a London Hospital.

The freehold residence of Sea Copse Hill, Whimingham, Isle of Wight, with grounds of nine acres, has been presented by Mrs. Frederick J. Kirchner as a free gift to the Royal Waterloo Hospital for Children and Women, to be used as a convalescent home.

**MEDICAL WAR ITEMS.**

Several medical men have enrolled themselves as special constables during the last few days. The price of hospital bedsteads has advanced 33½ per cent, owing to the increase in the cost of raw material.

Of the members of the St. John Ambulance Brigade 4,000 have mobilised, while there is a roll of 2,000 men waiting to sign on at a moment’s notice. Several X-ray specialists from London are proceeding to Belgium with apparatus to assist the surgical officers in cases of wounded, in the detection of bullets, fractures, etc.

The King has given to the Westminster Division of the British Red Cross Society, 74 Vincent Square, Westminster, an ambulance and a pair of his own horses for use during the war.

There is a considerable rush to attend classes in first aid and home nursing at the present time, and centres for such instruction are being given in many parts of London and other places.

A number of Cambridge men have volunteered to man a hospital transport ship to work between the Fleet and hospital ships and hospital cases on shore. Lady St. Helier, of 31 Portland Place, is acting as treasurer.

A new naval hospital, to be called “Queen Mary’s Royal Naval Hospital,” is to be opened immediately at Southend-on-Sea, for the purposes of which the Palace House has been placed at the disposal of a special committee which has been formed, of which Dr. W. Hale White is Chairman and Consulting Physician.

A dental unit, says the Guy’s Hospital Gazette, is proceeding shortlv, to Wimereux (Pas de Calais) to assist Mr. Newland Pedley, Consulting Dental Surgeon to Guy’s Hospital, in the formation of a private clinic for the dental treatment of the French and English troops, including the treatment of fractures of the jaw.

The Great Northern Central Hospital, Holloway, has placed 100 beds at the disposal of the Government, and a number of the 165 beds in the London Homoeopathic Hospital in Great Ormond Street, W.C., will be devoted, when required, to naval and military patients. The Board of Management of the Metropolitan Ear, Nose, and Throat Hospital have also decided to offer their services in support of the War Office, the staff having unanimously offered their services for the care of war patients. The Governors of Guy’s Hospital have offered the whole of the resources of their dental department to the War Office for the treatment of men offering themselves as recruits who have been rejected on the ground of defective teeth.

**NOTICES TO CORRESPONDENTS.**

Correspondents requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscribers," etc. Much confusion will be spared by attention to this rule.

**SUBSCRIPTIONS.**

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free on orders for abroad, 25s. Foreign subscribers who pay in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents, and will be supplied with this journal. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town, Messrs. Gordon, Robertson, of Sydney and Melbourne, are our special agents for Australia.

**OUR ARRIVALS.**

For Our Inscription.—Whole Page, £3; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following are made by the Press:—Whole Page, 13 insertions at £3 10s.; at £3 2s.; 52 insertions at £1 1s., and pre rates for smaller spaces. Small announcements of Practice, Assistances, Vacancies, Books, etc.—Seven lines or under (50 words), 4s. 6d. per insertion: 6d. per line beyond.
"Business as Usual." The partial paralysis of trade and all the complicated mechanism which goes to make up social existence, consequent upon the first declaration of hostilities in this country, is now, happily, beginning to show unmistakable signs of a revival. Thanks to the prompt intervention of the Government, food prices, which at one time threatened to be outrageous, have now been regulated, and there is every reason to believe that in this respect matters will further improve as the great trade routes at sea become once more opened up. Slowly but surely the masses are taking a saner outlook upon the general conduct of business, and hope, one of the greatest of mental stimulants, is beginning to awaken men's responsibilities to their King and country. It would be unreasonable, even on the part of the most independent citizen, to expect neither loss nor dislocation of some kind at this critical time in our history; but, at the same time, it is the bounden duty of every loyal subject to preserve, so far as may be possible, normal relationships with his fellow men and not, from motives of self-advancement or greed, to make their lot harder. There are many benevolent and combatant who will go under in the present strife. Let each one see to it, then, that he place no stumbling-block in his brother's way by making the conditions of life unnecessarily harder in this time of stress. Now that the wave of panic is subsiding it behoves us all to depart as little as possible from the ordinary tenor of our lives. In the foolish spirit of cancelling all holiday arrangements as short-sighted as it is selfish, for change of air is as necessary for tired workers as an influx of visitors into the seaside hotels and boarding-houses. In short, the motto of "Business as Usual" should be adopted in spirit, if not in letter, by all British subjects.

In some ways the medical profession in this country will be hardly hit during the war. Those practitioners who have left their practices and resigned their appointments to minister to the greater need of the sick and wounded abroad can rely upon their places being kept open for them by loyal and able auxiliaries. Some have returned to their practices in the absence of their partners, and others are suffering actual loss, probably of only a temporary character, from lack of regular patients and from the addition of extra gratuitous work. It is understood that, in order to adjust medical practice in Scotland while so many practitioners are away, a special Medical Service Emergency Committee has been formed which has made certain suggestions for the carrying on of medical work at home with as little dislocation as possible. This body has recommended that retired practitioners who are willing to step into the breach should send in their names forthwith to the Committee for registration and ultimate allocation to temporarily vacant practices. The suggestions that the visiting staff of public institutions should themselves undertake certain of the duties usually assigned to junior resident officers during the absence of the latter, and that school medical officers should be permitted to give at least part of their time to general work, strike us as being thoroughly practical, even if a trifle revolutionary, but in times like the present many of the accepted rules of medical etiquette and practice must be waived in favour of the common good.

Some wise advice was given by Lord Kitchener to the soldiers of the British Expeditionary force upon their departure to the front. After the usual martial and patriotic monitions he dwelt upon the desirability of each man keeping himself as fit as possible, in order that he might serve his country to the best advantage. At that point the ordinary cut-and-dried official manifesto would have ended, but the War Secretary is not given to general phrases in a matter of this kind. He wound up with a specific warning against the temptations of wine and women to troops on active service. This is almost certainly the first occasion in modern times that a General has given detailed advice of that kind to his army, although it was common enough in Puritan and Presbyterian armies and others having strong religious convictions.

In one way this new departure reflects the greatly increased value War, Wine and some wise advice was given by Lord Kitchener to the soldiers of the British Expeditionary force upon their departure to the front. logical factor is therein concerned. Reducing the matter to its ultimate terms it seems probable that any harm to the individual soldier arising from intercurrence is not so much due to the act itself as to the risk of contracting venereal disease. In any case the British soldier will do well to lay the words of Lord Kitchener to heart. In times of peace the strength of the Army is seriously drained by the sickness due to venereal diseases. In times of war the injury inflicted by that class of disease is immensely increased by expending force, in which it is necessary to maintain the highest possible standard of general health.

A Famine in
"606." Of late the incidence of venereal disease has been reduced in both Army and Navy. Not only has the actual number of cases been lessened, but the average stay in hospital has undergone a similar decrease. To some extent this satisfactory state of affairs is no doubt due to the better class of men who now enter the ranks of the Army, and also in part to a better knowledge of the facts of the case and more careful supervision by the authorities. Another important factor is the great improvement in venereal which has taken place in the treatment of venereal disease of all kinds. It will be interesting to note what effect the sudden shortage in the supply of salvarsan and neo-salvarsan have upon the health statistics of the Army. Both forms of "606" are made exclusively in Germany by German firms by processes of the secret of which is carefully guarded. The course of time will be no doubt possible for the English chemists to produce salvarsan synthetically, but at the best they could hardly hope to achieve so difficult a task without many months of arduous investigation and experiment. Meanwhile war with Germany means a famine of salvarsan and neo-salvarsan, that is to say, after the available stock on hand in the United Kingdom is exhausted. It would be difficult to furnish a more striking illustration of the far-reaching effects of war than that afforded by the spectacle of syphilis wreaking its dread ravages upon a populace depleted of the marvellous specific remedy evolved by the genius of the great German scientist, Professor Ehrlich. It is curious to note that a philosophy ridden nation should devote its energies with equal fervour and success on the one hand to the destruction and on the other to the saving of human life.

Anesthetics for the Front. One of the most pressing needs of the military hospitals at the present moment appears to be chloroform, and there are also wanting men to administer it. It is appalling to think that the beneficent and conservative operations of surgery may be seriously hampered, and many of them rendered impracticable, by the lack of the all-important anaesthetic. Morphine may act as a partial substitute, but it is vastly inferior in any of the recognised general anaesthetics, while its use may jeopardise the success of many an operation, even in these days of rapid surgery. It will be interesting to learn whether intraspinal anaesthesia will be employed to any large extent in the base hospitals. For general simplicity of administration and rapidity of induction, the use of one of the chloroform mixtures with ether will probably still find favour, especially with civilian surgeons, not professional anaesthetists, who are called upon to act in that capacity. There can be no doubt that the prevention of shock from an operation is largely a matter of the anaesthetic, and for this reason, as well as to enable surgeons to do other work, there is a real demand for anaesthetic specialists at the front, for an operation has, obviously, a much better chance of success when the surgeon is untrammelled by any misgivings with regard to the safety of the patient. It is reported that several private gifts of chloroform have been made to the Belgian military hospitals, and for these gratitude must be expressed to the donors. There is urgent need, however, for more, and the attention of philanthropic patriots may well be called to the matter.

LEADING ARTICLES.

THE WAR AND THE DRUG SUPPLY.

The general dislocation of trade consequent upon the war has, if we except food, nowhere made itself more acutely felt than in connection with the supply of drugs. The intervention of Government regulation and the partial re-establishment of the shipping routes have, happily, done much to relieve distress consequent upon the diminished supply of food. In the case of drugs, however, the case is somewhat different. A large number of synthetic preparations are manufactured almost entirely in Germany, and for many years past practitioners in this country have been accustomed to employ them on account of their superiority, in many respects, to similar remedies made by home industry. The supply of all these so-called fine chemicals is now cut off until the war is over. Other drugs such as the bromides, and particularly potassium bromide, have rapidly risen to famine prices, owing to the fact that the mineral deposits from which they are at present obtained are found chiefly in Germany. It is most opportune, therefore, that, upon the recommendation of Sir Thomas Barlow, K.C.V.O., and the British Medical Association, a professional Committee has been appointed by the Government to "consider questions arising in connection with the supply of drugs for curative purposes in the United Kingdom, with special reference to the ways in which the medical profession can assist in effecting economies in the use of these drugs of which the supplies are at present small." The following members have been appointed to act upon this Committee, of which Mr. J. Smith Whitaker is the chairman—Sir Thomas Barlow, Bart., K.C.V.O.; Sir T. Lauder Brunton, Bart.; and Drs. A. Cox, E. Rowland Fothergill, B. A. Richmond, F. J. Smith, W. Hale White, and E. W. Adams (Secretary). The principal departments of medical practice are well represented upon this advisory body which has already issued certain notes for the individual guidance of medical practitioners as to how they can economise with certain drugs. It is realised that there are many drugs, the shortage of which is merely temporary, and the sources of supply of these may be re-opened or alternative sources found, within a comparatively short period. In the case of other drugs already referred to the resources of the pharmacopoeia must be tapped in order to find substitutes, more or less efficient, no
CURRENT TOPICS.

The Way Round.

We all know that our drugs are costing us more. If we did not the confidential circular issued by the Government would make us realise it. Apart from the necessary shortage brought about by interruption of communication and an increased demand—which, after all, are only temporary factors—there is the fact that heretofore we have largely depended on the Continent for many of our supplies—notably salicylic acid and its many derivatives, potassium salts and the enormous mass of synthetic products produced mostly in Germany, which have lately found favour amongst us. Now we are expressly prohibited by Royal Proclamation from trading with the enemy, which term covers any person in the German Empire. There is, however, an exception which may be a matter of considerable importance to us—"This Proclamation shall not apply to the trading or commercial intercourse carried on by such person solely from or by such houses or branches of business in such other country." Now, several of the great German chemical houses possess branches or agencies of some sort or other in neutral countries, especially in Great Britain and America, and it seems quite possible that business may be resumed in this round-about way. Of course, there is no prohibition against selling stocks obtained here previous to the declaration of war, and it is apparently possible that we may in the way indicated obtain a share of such subsequent supplies as are available. The question of patriotism hardly occurs. To refuse goods on which the health or even the life of our people may depend, in order to keep a few shillings out of the enemy's pocket, would be a short-sighted policy indeed. And, in addition, in our professional capacities, we are international. We are not combatants but adjusters of the results of combat. We would do our best for the friend or foe who needed us alike. So it were the veriest folly to deny ourselves lawful therapeutic weapons needlessly.

Ambulance Work in War.

The whole country is responding to the Government's call. Everywhere we hear of nothing but corps and rumours of corps. The first idea of the man in the street is to get to the enemy; his ideal is a pair of puttees and a rifle. So be it. In addition to the civilian definitely militant, we find the civilian expectant—the man who thinks to a certain extent and realises that there is such a thing as disorganisation in various forms. Business, family or other reasons keep him from volunteering, and, accompanied by his womenkind, he applies to the varied powers that be for ambulance training. Everybody is taking out courses in first-aid and kindred arts. A great many are impelled to do so by an unquenchable and highly laudable impulse to do something, no matter what. Comparatively few ask what is or will be the ultimate use of so many lectures, demonstrations, and examinations. They realise that the short training they will get will not fit them to understudy the Royal Army Medical Corps on the march in battle, and therefore do not know what else there is for them to do. It is for the medical profession, who will be called upon to teach these eager and largely ignorant throats, to know the exact why and wherefore of all these efforts, and, as we have often found a discreet vagueness in answering the insistent "qui bono?" of the class, let us get the thing down plainly for once.

B.O. 183, issued by the St. John Ambulance Brigade, contains the following as the duties of Brigade Volunteer Aid Detachments:—"They will be expected to be able to give intelligent assistance in the transport of and attendance on sick and wounded in a war of invasion under the direction of senior officers of the Army Medical Service. They will be employed on the lines of communication between the field ambulances and the general hospitals in the following positions: Clearing hospitals, entraining stations, ambulance trains... Rest stations, private hospitals, conveyance homes." Here we have our duties in a nutshell; they apply to all, that is, we now know what our ambulance detachments are part of the country's considered scheme, and for the future we hope to hear no one suggesting that ambulance and nursing classes are a waste of time or a work of supererogation.

The New Recruits.

The physical standard of the new recruits has surprised and delighted the War Office. The number of rejections for physical unfitness has reached a record, far below anything that was expected. This, no doubt, is largely due to the class of men which is presenting itself for enlistment. In times of peace the War Office finds its efforts limited principally to the wastrel class, the poorer members of the community to whom enlistment in the army offers the only chance of relief from degrading poverty. Their descent appears to be mostly the result of the want of sustenance to stave off the pangs of hunger, they contract the habit of smoking to excess cheap cigarettes; tobacco takes the place of food, and from its baneful effects the candidate for enlistment is mostly rendered unfit for the requirements of military service. On the other hand, this class of recruit is largely drawn from the most favoured classes of the community. In them, no doubt, is reflected the good purpose served to the nation by the manly spirit of athleticism. From
the cricket fields, the tennis courts, the football fields, the golf courses and hockey clubs, there have promised various opportunities, and, amongst youths, whose energy and physique have been built up by their passion for the national games. Every now and then the cry has asserted its pessimistic note, that as a race we are degenerating; the proof of which was claimed in the evidence of the rejection at the recruiting stations. The reports in this regard have from time to time made some impression upon the public mind that the pessimists had good ground for their assertions. Happily, however, this war has clearly established that the pessimism of the pessimists was unfounded and wrong. Poor underfed kids are no reflex of the manhood of the nation; but even they, with good chances, can often be converted into good material for the nation's requirements.

The Medical Profession and Bonesetters.

The claim by laymen for bonesetters—so-called—to be entitled to a niche in the temple of medicine is perennial. They talk of justice, of fairness, of the trades unionism of doctors, and punctuate their convictions by pointing to the expert knowledge of bonesetters. And the absence of it in regular members of the profession. Of course, many cases of marvellous cures are related, where the doctors have failed and the bonesetters succeeded. A few weeks ago a long discussion was maintained in one of the morning papers upon the skill and capability of a certain bonesetter, of which examples were given. The editorial was leftly expressed against the medical profession, and howls of execration greeted the insertion of a communication from a medical man who ventured to express the professional aspect of the case, by succeeding correspondents. Curiously enough, too, one or two medical men took the laymen's side, and affirmed their belief in the bonesetter's art. But we do not propose to reopen these arguments in explanation of the attitude of the profession upon this question. That ethical position has been clearly defined upon many occasions. We should, however, like to point out that laymen make the mistake of believing that it is with the power to admit bonesetters, as members of their community. That power does not belong to the medical profession. The question is one which bears solely upon the medical acts. Unqualified practitioners of medicine or surgery are not recognised by the State. On the other hand, if qualified members of the profession, even in good faith, lend any of their support to unqualified practice, their action in this regard becomes illegal, and punishment overtakes them. With the public, however, the matter is different. There is no law prohibiting a layman employing whom he likes to cure him of his ills. But the State cannot tolerate the unqualified and unskilled practice. If the layman elects to consult a bonesetter the matter is purely one between himself and the man whom he chooses. We do not deny that evidence is in favour of the usefulness in some cases of the manipulations of bonesetters, but this can scarcely be urged as a plea in favour of medical men lending their support to unqualified practice—apart from the illegality of the proceeding.

Vaccination in Ireland.

Until within the last few years Ireland was the best vaccinated part of the kingdom, and one of the best vaccinated countries of the world. Unfortunately, the anti-vaccination campaign found a footing in certain districts, and boards of guar-

dians refused to enforce the vaccination laws. The Local Government Board, with whom the responsibility devolves upon them and the medical officers of Irish counties neglect their duties, contented itself with giving mild advice, and took no real measures to see that the laws were obeyed. The results are shown in a return recently published by the Registrar-General. In the year 1912, 82 per cent. of the children born were returned as successfully vaccinated. In 1909 this had fallen to 78·3 per cent. In 1911 it was 72·6 per cent. In 1912 it was further reduced to 66·3 per cent. The falling-off is definitely associated geographically with the anti-vaccinist campaign. It is most marked in the south-east corner of Ireland, and hardly noticed at all in Ulster. Thus, in, e.g., Wexford, only one in seven children born was vaccinated. In Tyrone, Antrim, and Londonderry the percentage of those unvaccinated and preferred to be left unvaccinated was negligible. The Local Government Board, by its negligence, has allowed a very serious condition of affairs to arise.

Sugar and the War.

By doubling the price of sugar, the war has brought home to the householder the need for economy in the consumption of this useful commodity. Sugar may be regarded in two aspects: first as a necessity, and secondly as a luxury. In both respects it is liable to be consumed in excess. As a necessity, of course, sugar is invaluable in the form of a nutritive substance. It serves the double purpose of increasing the nutritive value of other food, while at the same time rendering the latter more acceptable to the palate. In the form of a luxury it figures as so-called "sweets," of which the confectioner's art has produced an endless variety. Hence the person who is said to have a "sweet tooth" is one to whom all sweet things are agreeable, and so is engendered the habit of gratifying that "penchant upon all available occasions. But sugar in excess "dumps" into the human machine is by no means harmless in its effects. Many human ills, directly or indirectly, are the consequence. In the indolent, inconvenient phlegm is a common tendency; dental trouble, again, is often a direct result, for sugar possesses a solvent action upon the enamel which preserves the integrity of a tooth. Again, gastric disturbance is provoking dyspepsia, destructive intestinal fermentation, and the changes produced in the blood indicated in the evolution of certain dermato-

The Psychology of Patience.

The man who first described patience as a virtue was a philosopher to whom the world has since been indebted. His simple enunciation of a great truth showed the means by which the great
burden of exercising patience could be lessened and more easily sustained. Patience, having been endowed with the dignity of a virtue furnishes an ideal at which to aim, namely, that of a high degree of mental control, both of mind and body. The "immortal William"—not the gentleman at present suffering from a bad attack of megalomania—has said: "How poor are they that have not patience," and again:

"Tis all men's office to speak patience To those that wring under the load of sorrow."

The burden of exercising patience has been cast upon us in this country; the patience of waiting for news which never comes, the patience of the moment, in which is concealed from us information which the exigencies of the occasion demand to be kept secret. Among many thousands of our countrymen and women this burden of patience will exact much fortitude and resolution to prevent the support of moral courage from breaking under the strain. Let these, therefore, bear in remembrance that a healthy mind in a healthy body is the first necessary condition to enable them to deal with the burden under which they labour. The maintenance of strength of body and of mind is a sure means for combating successfully the trials of the situation.

Water-borne Diseases. Many rumours have been current during the past week or two of attempts being made to poison the water supplies in various districts, the majority, if not all, of these being absolutely without foundation. Local authorities are fully alive, however, to the possibility of such malicious contamination of water destined for drinking purposes, and the curious sight may be witnessed in some parts of London of the guard rails of the entrances to reservoirs by Territorials. As a matter of fact it would be almost a physical impossibility to poison drinking-water by chemicals in bulk without being detected, and even if this were to be carried out it is doubtful whether the quantity so introduced would be sufficient to produce the desired effect. Far more deadly would be the contamination of a water-supply by pathogenic microorganisms of the variety known to be transmitted by this channel. There is a greater necessity than ever of keeping water supplies up to the bacteriological standard of safety. This warning was uttered only last July at the Congress of the Royal Institute of Public Health, held in Edinburgh, when Prof. J. M. Beattie read an address in the absence of Prof. Ritchie before the Section of Bacteriology and Comparative Pathology on the relationship of bacteriology to water-borne disease. In some country districts the danger of polluted wells still exists, and even in places where the supply is taken from rivers or reservoirs it not infrequently happens that coliform bacilli find their way into the water. The frequent bacteriological examinations of water supplies, however, are almost all admissible in the interests of public health, and never was it more urgently required than at the present time. In the meanwhile it is safer to boil all drinking water in cases where the slightest doubt exists as to its purity.

The Office of Coroner. A movement is on foot in America to abolish the office of coroner. It is held that in order to determine the exact cause of death the coroner is compelled to call in the aid of experts to decide the matter for him. Again, it is maintained that the coroner's jury is a useless expense, inasmuch as their verdicts are in accord with instruction furnished by the expert evidence. The idea seems to be that instead of a coroner being called upon to inquire into the cause of death the case should be made over to the police from the beginning. So in America a Board of Inquiry would be constituted, consisting of a skilled pathologist, the district attorney, and a representative of the police department, to investigate every case in which the cause of death was uncertain, either in consequence of the suspicion of crime or from any other reason. This board would be empowered to summon witnesses, and the cause of death having been determined, the matter would end, save in cases in which evidence was forthcoming of the commission of crime, when the police would take action with a view to the arrest of the suspect or suspect person. The proposed change seems to have been suggested on the score of economy, though it is doubtful if it would be more efficient than the present system. The coroner's court is admittedly a costly process in this country. The advance, however, of medical science has removed some of the difficulties of ascertaining the cause of death, and an inquest seems to be in some cases as a person of some expense and the means of making public facts which expert knowledge has already revealed. One advantage of such a reform may be best illustrated in the numerous cases in which inquests result in verdicts of death from natural causes. For example, an elderly man suddenly drops down as the result of a heart attack because no one can tell the means by which death took place, the machinery of the coroner's court is set in motion to determine the point. Then a post-mortem reveals rupture of a cerebral artery and cerebral hemorrhage. Under the alternative system the dead body would at once pass into the hands of the police; the police would then summon a coroner, and having found that the man had died naturally from cerebral hemorrhage, the matter would end. It is urged that economy, simplicity and efficiency would be attained, in the place of unnecessary formality, expense, and the interruption to business generally entailed upon the attendant jurors. The details of the system, of which the above is a mere outline, would naturally require careful consideration in order to achieve the object in view. Some responsible official would have to preside at such an inquest, and it hardly seems likely that the ancient office of coroner, held as it generally is by professional men qualified in medicine and law, will be superseded in this country yet awhile.

PERSONAL.

Dr. EARLDEY HOLLAND, M.D.Lond., M.R.C.P., F.R.C.S., has been appointed Assistant Obstetric Physician to King's College Hospital.

Dr. H. Drinkwater, of Wrexham, has been elected President of the North Wales Branch of the British Medical Association for the ensuing year.

Dr. Alexander Gibb Glass, M.A., M.D.Edin., D.P.H., has been appointed an Assistant Medical Officer under the Durham County Education Committee.

Dr. Oliver Field has been appointed Deputy Medical Officer of Health for Wandsworth during the absence of Dr. P. Caldwell Smith, who is serving with the Territorial Force.

Two private wards at the Newbury District Hospital were opened the other day as a memorial to the late Dr. R. J. Kerby, a well-known practitioner who was greatly esteemed in the district.
CLINICAL LECTURE

ON

MITRAL STENOSIS: ITS PROGNOSIS AND TREATMENT. (a)

By R. OSWALD MOORE, M.D.Oxon., F.R.C.P.Lond.,
Consulting Physician to the Western General Dispensary, Marylebone; Physician to the Hospital for Diseases of the Heart.

Clinically the ordinary picture of a case of mitral stenosis is well known to all practitioners. The most common case is that of a young woman, say, between 17 and 30, who comes complaining of shortness of breath, or headaches, or cough, or some symptoms of indigestion. To all appearance it might be a case of anaemia, simple dyspepsia, or perhaps phthisis; at this stage nothing but an examination of the chest will disclose the cardiac lesion, which is frequently detected without there being any cardiac symptoms at all. In this guise the previous history will generally disclose the fact that the patient has suffered from rheumatism, chorea or frequent quinsies, or it may be scarlet fever; in very many cases, however, there may be no history of previous illness. Nearly all such cases are, I think, primarily rheumatic, especially when one realises how slight and indolent may be the manifestations of rheumatism in early child-hood—nothing more, perhaps, than transient pains in the limbs which may be mistaken for growing pains, or a temporary stiffness of the neck. As compared with mitral regurgitation there is no doubt that mitral stenosis is associated with less pronounced forms of rheumatic fever. Some, however, have maintained that mitral stenosis is sometimes of congenital origin, but I have failed to discover any satisfactory evidence of this.

Mitr al stenosis does, indeed, sometimes occur as a result of arterio-sclerosis, but this is not at all common, and appears at a later age than the more ordinary form. Speaking generally, mitral stenosis is more frequently met with than mitral regurgitation, and we find most frequently in women between the ages of 22 and 40. It is rare to meet with clear evidence of mitral stenosis under the age of 10, though mitral regurgitation is common enough in quite early childhood, but the lesion of stenosis takes some time to develop, as it is due to the slow contraction of mitral fibrous tissue. It is true in children the left auricle does not usually contract with sufficient force to give rise to the presystolic murmur. On the other hand, cases of mitral stenosis in patients over 40 are more usually of the arterio-sclerotic type.

Diagnosis.—In its more obvious aspect mitral stenosis is the easiest to diagnose of all the cardiac lesions; palpation along the left side of the chest being often sufficient for the purpose, as the presystolic thrill (often best felt in the sitting posture with the body bent forwards) is most characteristic of the lesion and the long, rumbling presystolic murmurs running up to the first sound and varying in limited area is equally significant. In my experience this murmur is often heard in the recumbent posture, when it has not been audible with the patient standing up—particularly if he is made to raise the left arm. The only case in which a presystolic murmur can lead us astray in diagnosis is when, in aortic regurgitation, the regurgitation of blood into the left auricle brings about a virtual stenosis at the mitral orifice; this goes under the name of Flint's Murmur. It may be distinguished from the true presystolic murmur of mitral stenosis as follows: (1) It is never so loud or rasping; (2) the presystolic thrill very rarely accompanies Flint's Murmur; (3) the systolic shock is tapping in mitral stenosis, forcible and rather heaving in aortic regurgitation with a Flint's Murmur.

In an ordinary well-compensated case we should expect to find accentuation of the pulmonary second sound, owing to the increased tension in the pulmonar y area caused by the obstruction at the mitral orifice. At times we may find a reduplicated second sound in the pulmonary area or at the apex, where it is due to the first inrush of blood in the ventricle, such inrush being more sudden and forcible than under normal conditions from the increased blood pressure in the left auricle due to obstruction of the mitral orifice. The cardiac dullness is increased to the right; owing to atrophy, rather than hypertrophy, of the left ventricle, the dullness is not likely to be much, if at all, increased to the left. There is often a more pronounced enlargement of the right side of the heart in mitral stenosis than in mitral regurgitation.

In those cases which develop in connection with arteriosclerotic disease, however, the increased pressure of the second sound, because the blood pressure will be raised in the systemic circulation owing to: the arteriosclerosis no less than in the pulmonary area, hence the two sounds will be approximately equal and there will be no reduplication.

As the disease progresses the auricle becomes gradually weaker, and consequently it has no longer sufficient force to produce the presystolic or auriculo-systolic murmur, hence we may hear in its place a mid-diastolic or even an early diastolic murmur. This latter one must be careful not to confound with the murmur of aortic regurgitation, which is softer and more bounding in character, and not less obvious in the region of the apex. This is the point at which to speak of auricular fibrillation, about which so much has been said by recent writers on cardiac disease. Though auricular fibrillation may occur under a variety of circumstances in which there is degeneration of the myocardium, it is with mitral stenosis that it is particularly associated, so I will just say a few words about it here, though it would be more suitably dealt with in a lecture on cardiac arrhythmia.

Now, the ordinary beat of the heart starts at the mouth of the great veins opening into the auricles, and this is known as the 'sino-auricular node.' Beginning here the impulse passes down the auricles along the auriculo-ventricular band or bundle of His to the ventricles. This is the normal mechanism of the heart beat. But, in various conditions of disease the impulse does not start in the normal place, but in other positions, and then the fibres of the auricle may contract irregularly with no sort of co-ordination; the muscular walls of the auricles are in a position of diastole, complete systole is never accomplished, the structure as a whole rests immobile, close observation of the muscle surface reveals extreme and incessant activity, rapid and minute twitching with an un-
Clinical

Definitely has had well he the mentalization normal of frequent presystolic sound only which aortic sound are mistaken of hemiplegia, catarrh, usually traction. whipped the feet, dilated in tissue; insurance of passive congestion, may be mistaken for indigestion, or general malaise, and the physical examination discloses a pre-systolic thrill and murmur at the apex; such symptoms are probably not due to the cardiac lesion, they may be readily removed by some quite simple treatment, and years may elapse before the patient again appears with signs of a definitely broken compensation. Women, by reason of the greater tranquillity and sedentary character of their lives, are able to continue for a longer time than men unaffected by this lesion. As, however, the narrowing of the orifice becomes more pronounced, only a small volume of blood is ejected into the arterial system at each systole, the general nutrition becomes correspondingly poor, the complications in the lungs become more probable, the normal metabolic processes are interfered with and general nutrition becomes defective.

When once the compensation has broken down it is restored much easier than in the case with mitral regurgitation, because the narrowing of the mitral orifice causes an imperfect filling of the left ventricle, so that the heart itself obtains an insufficient supply of blood and thereby cardiac weakness is promoted. When mitral stenosis is established in late childhood it has a worse prognosis than if it first occurs in adult life, partly owing to the progressive tendency of the constriction of the orifice, which is more marked in early life, and partly owing to the fact that the stenosed orifice does not increase in size while the growth of the heart continues.

In considering the case of a young adult of either sex with a compensated mitral stenosis, the prognosis will depend on the nature of the work and the ease with which the patient can continue his occupation, and on the first premonitions of an impending breakdown; then again, the whole condition of his life, the house in which he lives and the climate must be considered. Still more important is it, in my opinion, to take fully into consideration the rheumatic history of the parents and collaterals, for the likelihood of a further attack of rheumatic fever will have a most unfavourable influence upon the prognosis.

In the case of women the question of pregnancy and childbirth often comes before us, and in many cases I think we may take a fairly favourable view; thus, if the cardiac lesion is well compensated, matrimony may be permitted; if there have been one or two previous breakdowns, if allowed at all, it must only be after giving full warning of possible dangers. Should the patient have reached the stage of pulmonary congestion with albuminuria, then marriage is clearly quite out of the question. As an instance of how well these patients may pass through pregnancy and childbirth: (1) I had a woman, art. 24, who came to me at the hospital suffering from mitral stenosis and regurgitation—she had had her marriage at the age of 12, and her mother had suffered from it four times; palpitation of the heart and dyspnoea were severe. She improved very much
under treatment, and compensation was restored.
I did not see her again till five years later, when
she came to the hospital at my request, and
found that she had married three times previously
and had given birth to a child which she had
nursed for 13 months. The physical signs were
unchanged, but she had no cardiac symptoms. (2)
Another case was a woman, act. 22, with mitral
stenosis and regurgulation, who improved a
good deal while an in-patient at the hospital for six
weeks. She appeared again four years later, when
she had been married 18 months, had had a
child seven months old, which she had nursed for
two months; though short of breath, her general
condition was distinctly better than when I had seen
her four years previously.
A few months ago I had a letter from a doctor
in Nova Scotia detailing the case of a woman who
had mitral stenosis in early life, but passed success-
fully through 12 pregnancies and reached the age
of 50 before there was a serious cardiac break-
down.
Hemoptysis, pointing to engorgement of the
pulmonary circulation and rupture of blood-vessels,
is rather a serious symptom. Hemiplegia, due to
thrombosis, generally admits of a speedy recovery,
which may be permanent.
Secondly with regard to prognosis may be
derived from the physical signs. It is important
to note carefully the second sound at the apex; so
long as the second sound is audible at and beyond
the apex, there is little or no liability to the
occurrence of symptoms, and no immediate danger
of a cardiac breakdown; when, however, the
second sound is no longer audible at the apex
through any cause, it will be no symptoms under
ordinary conditions of life, any slight extra exertion
may provoke them. The disappearance of the
presystolic murmur and the substitution for it of
a mid-diastolic or early diastole murmur is an
unfavourable sign, indicating as it does an in-
creasing feebleness of the left auricle; the advent
of the auricular fibrillation is a definitely unfavour-
able condition, though it is fairly amenable to
treatment, and a patient with it may live as much
as ten years, yet the compensation of the heart
is never completely restored. It is important to
note the accentuation of the second sound in the
pulmonary area, for, as it diminishes in intensity
we get evidence of the failing of the right ventricle.
The cases of mitral stenosis associated with
arterio-sclerosis have, of course, a much less
favourable prognosis, because the lesion is
necessarily progressive. The future, in fact,
depends on the rapidity of the advance of the
sclerotic process of the valves and heart muscle.
In these cases the dyspnea is particularly distressing,
and they sometimes die suddenly from angina
pectoris. Thrombosis is common in this form of
mitral disease, whereas embolism is more
characteristic of the endocarditic forms which we
have been discussing, giving rise, if pulmonary,
to infarcts and a localised pneumonia, while, if
cerebral, causing hemiplegia. Cardiac arrhythmia,
which is not so common in the pure forms of
mitral stenosis, occurs frequently in these arte-
ro-sclerotic cases, owing to the sclerosis of the
myocardium and the fact that the heart has to
struggle against hypertension in the systemic as
well as in the pulmonary circulation.

Treatment.—This does not differ materially from
that of other forms of valvar lesion; it is always
a question of estimating the strength of the heart
for doing its daily work and considering how far
this may be reduced. At first when the patient
comes complaining of breathlessness on exertion,
it is quite possible to resume ordinary life
again in a somewhat less active way. Later on,
when there is a definite breakdown, the question
of drug treatment arises. In many cases con-
siderable benefit will be found to arise from
ordinary tonic doses of iron and arsenic, if these
are unsuccessful, small doses of digitalis may well
be tried; in those cases in which small doses of
digitalis continued over a long time prove so very
efficacious. When, however, the condition is one
which is described as auricular fibrillation, of which
we have spoken above, then is the time for large
doses of digitalis—say, m. x. every four hours, of
course, with the patient at rest in bed. The
digitalis is here thought to act by protecting the
ventricle against excessive stimulation from the
auricle by inhibiting the conduction of impulses in
the bundle of His. When there is much oedema
of the legs it is difficult to improve on the well-
known diuretic or Niepceur's pill, which consists of:

Pil. hydr., gr. j.;
Scillae, gr. j.;
Digitalis, gr. j.,
which is most effective in removing the oedema
and minor degrees of ascites. When this line of
treatment fails, I have found most satisfaction from
theobromine, gr. v. t.d.s., which is a powerful
diuretic and also has a tonic effect upon the
heart. In cases where the ascites or pleural effusion
is at all considerable, tapping must, of course, be
resorted to. In the cases in which the mitral
stenosis is associated with arterio-sclerosis and, as
is often the case with renal cirrhosis, then the line
of treatment must be mainly dietetic, and consists in
avoiding nitrogenuous food and all uric acid
producers, while employing drugs which lower the
arterial tension, such as the iodides and nitrates.
Digitalis, on the other hand, is usually unsuitable
in this form of mitral stenosis.

Note.—A Clinical Lecture by a well-known teacher
appears in each number of this Journal. The lecture
for next week will be by Sir Arbutniet Lane, Bart.,
M.S., F.R.C.S., Senior Surgeon to Guy's Hospital,
and to the Hospital for Sick Children. Subject:
"Fractures."

ORIGINAL PAPERS.

THE
EMPLOYMENT OF HYPOPHYSARY
OPERTHERAPY IN GYNECOLOGI-
CAL PRACTICE: ITS IMMEDIATE
RESULTS. (a)

By PROF. M. F. JAYLE.

[Specially Reported for this Journal]

The relations between the ovarian gland and the
other ductless glands have now been for many years
the collective object of researches, of which the
results, although they are still in large proportion
without the limiting border of accurately definable
precision, are nevertheless capable of translation into
the language and applied practice of some positive
realities. One method of studying these relations
consists of the recurrence in clinical experimentation
of the time-honoured methods of ophotherapy.

(a) These researches were carried out in the gynecological
clique of the Faculty (Prof. S. Puzzi), at the Hospital Broa.
In this way I have recently been led to try the effects producible by the administration of pituitary gland to female patients affected with various utero-ovarian pathological troubles.

In carrying out these clinical investigations I had recourse to the hypophyseal fluid prepared by the method adopted by Choay. The gland selected is that of the ox, of which the mean weight is 2.2 grammes; 1.8 for the anterior lobe, and 0.4 for the posterior. (b) The hypophysis is treated by desiccation in vacuo, which yields 0.5 grammes of powder for the whole organ, 0.4 for the anterior lobe, and 0.1 grammes for the posterior. This powder is used in the preparation of the solution to be injected. It is divided into three parts; of these it is treated with solvents which extract from it certain active substances of which the nature has not hitherto been precisely ascertained. The solution thus charged with the active substances is subjected to a process of concentration till a dry residue is obtained. This residue is then dissolved in an aqueous solution of sodium nitrate, to which a solution of the base is added; and then the latter is gradually heated to ebullition, so that the thermostable constituents only are now left, and the noxious principles produced by microbiic action have completely disappeared. The direct consequence of following out this mode of procedure is that the injected solution contains but a restricted proportion of the active substances of the gland; the powder which has hitherto utilised only the solution prepared from the posterior lobe. Each ampulla contains 1 c.c. of this solution which corresponds to 0.05 grammes of the powdered posterior lobe of the hypophysis—that is to say, to one-half of that lobe.

The hypodermic injections were made beneath the skin of the posterior aspect of the thigh, on the upper outer, and a little below it, and the injections were given at intervals of two days, and daily in some exceptional cases. The quantity administered was at first that contained in a single ampulla, but I have been led by experience to recommend commencing with a third or a half, with the object of minimising the slight, but quite clearly defined, indications of intolerance in My cases, especially at the initial stage of the treatment. It has seemed, in the progress of my experience, that emaciated and intractable women bear somewhat large doses less well than do those of other types. Thus I have come to arrange a quadruple system of dosage (Nos. 1, 2, 3, 4), corresponding to the respective quantities of 2, 1, ½, and ¼ of the posterior lobe of the hypophysis, and I recommend beginning the course of administration of the remedy with the No. 1 dosage and a gradual increase till the No. 4 has been reached. In treating hemorrhages, I practise daily injections; in other cases, I adopt a series of ten injections, administered on alternate days, and the intervals between which are successively twenty-four, forty-eight, or six days, according to the requirements indicated by the conditions of the individual case. The amount of dose can also be graduated in the course of treatment from No. 1 to No. 4.

The injections are either painful to a very slight degree or quite painless. In my series of more than 400 cases, only one patient was found to have ever produced the effects are immediately manifest. The patient blanches at once and retains the palloid tint for several hours. She usually experiences some colicky pains, and in a good many instances complains of headache during the first day and insomnia during the first night. Generally speaking, the injection produces a feeling of fatigue and I accordingly advise patients to take complete rest on the day on which the injection is administered. For this reason, too, it is best to have it given in the patient's home.

The effects obtained have been: diminution and, fairly often, complete arrest of local discharges, whether red, yellow, or white; diminution, and fairly often, complete arrest of abdominal pains; diminution of congestion, of wandering—so-called rheumatic—pains of the limbs; suppression of menstrual clottings, while, with regard to the menstrual period itself, I have in most cases noted a diminution of the interval; exceptionally an increase, and occasionally a regularisation. I have treated by this procedure various patients suffering from chronic hypophysary over-secretions, uterine subinvolutions with metrorrhagia, uterine sclerosis of the menopause period accompanied with metrorrhagia, chronic non-suppurative salpingitis, chronic ovaritis, uterine fibroma, inoperable epiphlebitis of the cervix accompanied with haemorrhage. In order to estiimate the result more accurately I have suppressed the use of all dressings, and, frequently even the vaginal injections. The immediate result has proved satisfactory, and I do not hesitate to recommend this therapeutic procedure at the present date, while awaiting the revelations of the remote ones.

Thus hypophysary epo-thetepny seems to me to render distinct service in cases of young women affected with metastatic Fallopian tubes and peritoneum, which, while of comparatively slight nature, prove rebellious to ordinary treatment; also in those of women suffering from the metrorrhagia which accompanies the period of menopause, and in patients who are habitually tormented with attacks of recurring symptoms of pelvic congestion without any specific lesion. It may also prove useful as the complement of all conservative operations, when the results obtained by the latter have not been completely satisfactory. It may probably succeed in replacing electrotherapy, radiotherapy, and radium-therapy in certain indications for therapeutic procedures which have recently been relegated to the influence of the former.

The ovary (ovaria) seems a complex one, but we observe all the characteristic signs of vascular constriction. Nevertheless, it has appeared to me from the observation of certain facts that the ovary is itself influenced in its secretary function by the effects of administration of the substance of the hypophysis. The results of some observations which I have sketched here for the reader will enable him to render count of the immediate effects of hypophysary epo-thetepny. They are taken from the reports of the series of cases which I treated in the Hôtel Broca, in the service of my chief, Professor Pozzi, and of patients treated in my city practice. I have at present fifty cases actually under treatment, and the immediate results which I have obtained in the whole, have been decidedly favourable. Those reached in the series of ten cases here specially presented, and which have been taken at random from the general report, will enable him to estimate the effects of hypophysary epo-thetepny, which have usually been very favourable, and sometimes nil (as in obs. IX.).

Obs. 1.—Metritis. The patient, at the age of 23, was a nullipara. There was an enormous hypertrophy of the cervix; the ovaritis was more marked on the left side. Ten hypodermic injections were given between January 12th and February 12th. Improvement of the menstrual disorder and relief from pain followed immediately, and the latter had completely dis-

appeared after the sixth injection. The cervix was improved, but not quite cured; accordingly treatment with hot air was commenced. The improvement continued through March; an injection was given every sixth day, and at the end of the month the patient felt well. Menstruation had occurred twice since the beginning of the treatment; the flow was less abundant and not accompanied, as before, by a sense of fatigue.

Ours. II. Chronic metritis with ulceration of cervix.

Double salpingo-ovaritis, more marked on left side (vomiting and distress with the left salpingitis.—The patient, aged 28, had menstruated at 12, and had shown some symptoms of pulmonary tuberculosis during the past ten years. Had had miscarriages at 21 and 24. There was copious menstrual discharge, also metrorrhagia. Eleven hypodermic injections were administered between January 12 and February 13. The improvement was immediate. Metrorrhagia ceased completely after the third injection. After the fourth injection the menstrual period was ten days in advance (they had usually been five or six days in advance), but there was no formation of clots—which had previously been always in evidence and very voluminous.

From the commencement of treatment, there was a history of hemorrhage. The patient, aged 26, had had an abortion on the 9th of December—after a month’s pregnancy. Loss of blood commenced from January 15 to February 10; during the last week of that period clots of the size of the closed fist had always been forming. From February 16 to 28 six hypodermic injections were administered. There was immediate amelioration of the haemorrhage, followed by its complete disappearance.

Ours. IV.—Pelvi-peritonitis without any extensive lesions.—Nulumpsa, aged 24, was neurotic and suffered from very severe pains, especially on the right side (diagnosis of appendicitis, of salpingitis, of abscess). Between January 27 and March 14 eleven hypodermic injections were administered. Marked amelioration of pain. Total disappearance of white discharge (which had not been very abundant). The last menstrual period has been greatly lessened after ten injections.

Ours. VI.—Metritis, double ovaritis, pelvis varicose, lysis.—Nulumpsa, aged 27, Menstrual period seven or eight days in advance. Loss of weight during hypodermic, 20 kilos. Had sought advice on account of the pain and discharge, both red and white, which had continued during the previous seven months, and went on increasing in quantity. Seven hypodermic injections were administered from February 6 to March 11. The pains disappeared completely; the vaginal discharges became increased. These appeared a week beforehand, and much more abundant (little more was lost during previous three months). Bowels more regular. At close of menstrual period some white and yellow discharge reappeared. At the end of March improvement continued, with the condition of continuing the treatment.

Ours. VII.—Metrorrhagia of three months’ standing.—Patient had menstruated at 15, and borne three children. For the preceding three months the red discharge had necessitated the use of a fresh napkin daily. No abdominal pain. Headache and renal pains during past ten days. Half-ampulla of cocaine injected daily for seven days. Hemorrhage almost quite disappeared after the first injection, and entirely after the third. The headache and renal pains disappeared very rapidly.

Ours. VIII.—Double chronic post-abortal salpingo-ovaritis.—Patient a nullumpsa, aged 10. An abortion of four years previous date had been the starting-point of her illness. Menstruation had commenced at 13 years; it was now a little irregular, and accompanied by clotted. She had sought advice on account of very acute abdominal and lumbar pains, and very copious yellow discharge. From February 15 to February 25 five hypodermic injections were administered, with much production of the pains and discharge. The menstrual flow then appeared at one date, less abundant and less painful, of deeper red colour, and with less clotting. After menstruation the patient felt well; then, on placing a longer interval between the injections, the pains began to regain their strength, though with diminished intensity. March 28th: improvement continues, but only on condition of continuing the treatment.

Ours. VIII. Parametritis. Pelvi-peritonitis.

Fixation of uterus.—Nulumpsa, aged 26. Miscarriage at four months, in 1910. Menstruation at 13. Since miscarriage, menstruation had been irregular and painful. Administration of fourteen hypodermic injections from January 26th to March 10th. Diminution of discharge and amelioration of pain after fifth injection. Menses appeared after tenth injection, and much more healthy than any of those of the preceding period. Pains disappeared after thirteenth injection. Menses on March 16th, which lasted four days (instead of five or six) and were accompanied with a small quantity, though with a little pain, and had appeared four days in advance. At the end of March all went well, on condition of repeating the injection every third day.

Ours. IX.—Cystic salpingo-ovaritis, with chronic parametritis and pelvi-peritonitis. Hyperplasia of hirsute system.—Nulumpsa, aged 22. From January 17th to February 10th seven hypodermic injections were given, without any satisfactory change in way of improvement.

Ours. X.—Inoperable epithelioma of cervix.—Patient, aged 48, had had red discharge during past year, accompanied during last three months with formation of clots. Very weak, stooped in walking, unable to maintain erect posture in standing, on account of severe pain in right side. The result, noted on March 24th, after ten hypodermic injections, was as follows:—Complete cessation of loss of blood; some yellow discharge only. Patient holds herself erect, walks with comfort and feels stronger. The pain in right side has greatly diminished. Urine more healthy. Constipation continues. Quite naturally there is no local amelioration.

THE PRESENT POSITION OF

OPHTHALMOLOGY IN SCHOOL HYGIENE. (a)

Dr ROBT. A. AASKINS, M.A., M.D.Dub., D.P.H.

CANTAB.

School Officer, Lancashire Education Committee.

OPHTHALMOLOGY is one of the largest branches of school hygiene, and both from the point of view of the teacher and of the child it is one of the most important, and yet it is a branch which is admittedly on a most unsatisfactory footing. One of the chief reasons for this is that eye work differs from other branches of school hygiene in that most doctors have not had the highly specialised training necessary for ophthalmic work, and it is not possible for the ordinary school child to employ the specialist; on the other hand, the country is flooded with opticians who cannot carry out the examination essential for prescribing glasses for children.

(a) Paper read at the Annual Meeting of the Royal Sanitary Institute, July, 1914.
In our schools at present there are numbers of children wearing wrong glasses. There is a further crying demand for improved methods in eye work for such problems as that which the large number of cases of squint present, a deformity which involves blindness in one eye, apart from its ugliness. In most places the decision as to whether a child needs glasses or not depends upon its failure or otherwise to read a given line on Snellen’s test types, which is a very unsatisfactory and, indeed, unscientific method. Snellen’s types are at best a very rough and often unreliable guide in the case of children, and they cannot be used for a very large and important section, viz., children who are unable to read.

At the opposite pole to illiterates, there are the children who read below our arbitrary line on Snellen’s types. There are a number of children who read 6/6 and even 6/6 and who yet require glasses. Assuming, however, that the child’s vision is defective to a definite extent as estimated by Snellen’s types, it is then absolutely necessary that the school doctor should know what is the cause of the defective vision, and for this reason alone, viz., that Snellen’s types give us no idea as to which of the widely differing causes of defective vision is present, the recommendation of children for glasses on an examination by Snellen’s types alone should be condemned. In the first place there are many cases of defective vision which are not due to refraction errors at all, and in any instance, the child may have a temporary spastic condition of the ciliary muscle, which may simply require a short rest to set right. I have known of many cases where such children have been told they require glasses. One case went twice a ten-hour journey there and back to an eye hospital to be informed of the fact. There are again cases of fundus conditions, small opacities, etc., which are brought to light by an ophthalmoscopic examination.

By far the most important point, however, is that the school doctor should know in the case of a rejected child whether the case is one of hypermetropia or myopia. I intend later to make a few remarks as to these conditions, so widely differing in aetiology, treatment, and prognosis, that the entire consideration of the case depends upon which is present, and will content myself here with stating that it is absolutely necessary for the doctor’s examination to disclose this fact.

A third reason why ophthalmoscopic work should be done in schools is the presence of a very large number of wrong glasses in schools. There are a number of children wearing actually harmful glasses, e.g., hypermetropic children wearing myopic glasses. Almost any eye will get a temporary increase in the sharpness of definition of objects by putting up a low minus glass, and this is the common resort of an unscrupulous shaman who cannot find any glass which will improve the child’s vision. The ultimate result of such treatment is disastrous. There is in addition a still larger number of children wearing glasses so bad that they are practically useless from a point of correcting the refraction error.

I need scarcely say that no doctor can tell whether a child’s glasses are correct without an ophthalmoscopic examination. It is asking the doctor to say whether the bottle and the dosage are correct before he knows what is the matter with the patient. I mention it, however, because the point is a serious one, and because there are very erroneous ideas on the subject among medical men. Assuming, then, that the present position of eye work in schools is unsatisfactory, what can be done to remedy this?

A proposal was made recently by some of the Staff of the Royal London Ophthalmic Hospital, where a large number of eye cases from the schools are treated by arrangement with the London County Council. They suggested that all children who do not read 6 0 in either eye as well as if they should be sent to the hospital or treatment centre for examination. This would, perhaps, be the ideal; but, as is sometimes the way with ideals, it is doubtful whether it would be possible to get so many children, a large number of whom do not require glasses, up to the hospital. Those who have experienced the difficulty of getting even cases we know to be serious to the hospitals will, I think, agree with me in this.

The correct plan, I think, is for the school doctor to carry out an ophthalmoscopic examination of eye cases in the school itself. With one exception, all difficulties are thus got rid of at a single stroke. This one difficulty is that the school doctor must be an experienced ophthalmologist, and really good work will not be done in this important branch of school hygiene, until all school doctors are trained ophthalmologists. The necessity for this has so often been emphasised elsewhere that I will not comment on it further here.

I come now to a point I put aside previously, a point on which I wish to lay emphasis. It is the necessity for the school doctor, having decided that the child’s eyesight is defective, knowing which of the causes of defective vision is present in a particular case.

Firstly in reference to myopia. I am quite aware that there are different views held on this point, but I think that the majority on one side is so great that we may assume that all cases of myopia should be fully corrected. In order to do this all cases of defective vision should be diagnosed by the ophthalmoscope. Further, as myopia, even of low degree, tends to increase in very many cases between the ages of, say, nine and fourteen, all such cases should be periodically examined with the ophthalmoscope in order to keep the strength of the glasses up to the proper level.

I would like to draw special attention to hypermetropia. I have felt convinced for years that in school work we are needlessly, nay, harmfully submitting large numbers of cases of low hypermetropia to the unpleasant burden of wearing glasses. I am well aware that I am hereuttering what many will regard as heresy. It may be mentioned that in the estimate given by Dorrell 77 per cent. of all people are reckoned to have such an error. As, however, the point is one which may meet with opposition, I will invoke the testimony of an ophthalmologist of the highest standing whose name is familiar to all of you. I refer to Mr. R. W. Doyne, from whose work I quote freely in what I am about to say. He expresses the point in somewhat striking terms in saying: ‘If the word “error” is used it will indicate an error.

I need scarcely say that no doctor can tell whether a child’s glasses are correct without an ophthalmoscopic examination. It is asking the doctor to say whether the bottle and the dosage are correct before he knows what is the matter with the patient. I mention it, however, because the point is a serious one, and because there are very erroneous ideas on the subject among medical men. Assuming, then, that the present position of eye work in schools is unsatisfactory, what can be done to remedy this?

A proposal was made recently by some of the Staff of the Royal London Ophthalmic Hospital, where a large number of eye cases from the schools are treated by arrangement with the London County Council. They suggested that all children who do not read 6 0 in either eye as well as if they should be sent to the hospital or treatment centre for examination. This would, perhaps, be the ideal; but, as is sometimes the way with ideals, it is doubtful whether it would be possible to get so many children, a large number of whom do not require glasses, up to the hospital. Those who have experienced the difficulty of getting even cases we know to be serious to the hospitals will, I think, agree with me in this.

The correct plan, I think, is for the school doctor to carry out an ophthalmoscopic examination of eye cases in the school itself. With one exception, all difficulties are thus got rid of at a single stroke. This one difficulty is that the school doctor must be an experienced ophthalmologist, and really good work will not be done in this important branch of school hygiene, until all school doctors are trained ophthalmologists. The necessity for this has so often been emphasised elsewhere that I will not comment on it further here.

I come now to a point I put aside previously, a point on which I wish to lay emphasis. It is the necessity for the school doctor, having decided that the child’s eyesight is defective, knowing which of the causes of defective vision is present in a particular case.

Firstly in reference to myopia. I am quite aware that there are different views held on this point, but I think that the majority on one side is so great that we may assume that all cases of myopia should be fully corrected. In order to do this all cases of defective vision should be diagnosed by the ophthalmoscope. Further, as myopia, even of low degree, tends to increase in very many cases between the ages of, say, nine and fourteen, all such cases should be periodically examined with the ophthalmoscope in order to keep the strength of the glasses up to the proper level.

I would like to draw special attention to hypermetropia. I have felt convinced for years that in school work we are needlessly, nay, harmfully submitting large numbers of cases of low hypermetropia to the unpleasant burden of wearing glasses. I am well aware that I am here uttering what many will regard as heresy. It may be mentioned that in the estimate given by Dorrell 77 per cent. of all people are reckoned to have such an error. As, however, the point is one which may meet with opposition, I will invoke the testimony of an ophthalmologist of the highest standing whose name is familiar to all of you. I refer to Mr. R. W. Doyne, from whose work I quote freely in what I am about to say. He expresses the point in somewhat striking terms in saying: ‘If the word “error” is used it will indicate an error.
is a very common thing to meet with in schools, and is more common in childhood than at any other period of life. Doyne divides eye-strain into two fairly distinct varieties, which I will consider separately. The first is due chiefly to peripheral conditions, i.e., in the eye itself. The second is chiefly due to central conditions, i.e., in the brain.

The most prominent feature of the first is pain and discomfort in the eye itself, especially at the back of the eye. This may be due firstly to a high degree of hypermetropia, error, which is definitely beyond the power of the ciliary muscle to counteract. In these cases glasses should undoubtedly be prescribed, whether for constant use or not depending upon the particular case in hand. Secondly, the cause of the peripheral eye-strain may be hypermetropia of low degree, and this is one of the classes of school children where glasses are often not only unnecessarily, but even wrongly prescribed. It is, to quote Mr. Doyne, as if a person has to walk many miles daily, and you put him to bed to develop his legs instead of encouraging careful exercise to increase his muscular vigour. Many such cases put into glasses are simply artificially manufactured invalids. Such cases require careful exercise of the eye and not glasses (except in certain instances). The child has got a little too fast and has exhausted his power temporarily. He requires to develop his ciliary muscles more carefully, by which means he can be put in a condition to do his work perfectly satisfactorily and be spared the infliction of wearing glasses. The latter course may simply mean prolonging or even rendering permanent the weakness. In cases of mild cardiac disease one does not recommend rest, but encourages a compensatory hypertrophy by means of exercises.

The second category of eye-strain to which I wish to refer is very common in school life, namely, the one due to central conditions, and chiefly to fatigue on the fusion centre. I can only go into the subject briefly, and must refer those who are interested to Mr. Doyne's paper, where the matter is fully gone into. The cause of eye-strain in cases characterised by headaches, often described as sick headaches, and confined chiefly to the frontal area. It is due not to fatigue of the ciliary muscles, but to exhaustion of the fusion centre of the brain. It is fatigue of this centre, or rather of the interaction of the fusion centre of the brain with lower centres controlling the ciliary muscles, that is the cause of the variety of eye-strain in children. It is not the ciliary muscle that is at fault. That this is the case is proved by the fact that those who have done much refractive work among children are familiar with, namely, the comparative rarity with which eye-strain is found in squinters, even where there is a considerable degree of hypermetropia, and also in one-eyed children. The reason for this is that although the ciliary muscle has just as much work to do, the fusion centre is no longer attempting to form binocular vision.

The same thing is exemplified by the extreme frequency of eye-strain in cases of anisometropia, the strain being due not to the ciliary muscle, but to exhaustion of the fusion centre of the brain which is attempting to fuse two very different images. Similarly in myopia, ocular headaches are much less common because no effort of the ciliary muscle can neutralise the myopia, and consequently the fusion centre does not exhaust itself in attempting to obtain a clear image, as it does in the case of hypermetropia. The treatment of most of these cases is suitable rest and suitable work, not glasses. At present the child is simply being, as it were, worked. I would like to anticipate an objection which will be raised, namely, that the error may cause the child to approximate its eyes to its work and so, owing to excessive convergence, possibly be a predisposing cause of myopia. If the child really cannot read comfortably without closely approaching its eyes to its work, then, by all means, put it into glasses. This will, however, only comparatively rarely be found to be the case in the class I am speaking of. I may mention that a much more fertile source of eye-strain, the eye-strain of approximation is habit acquired in infants' schools by the child doing work it is not fit to do at that age.

In summing up I would urge:—1. That the school doctor must be a trained ophthalmologist. Till this is the case we can have little hope of good eye work being done in schools.

2. That all cases of myopia should be picked out and receive a much more careful supervision than is the case at present. The ophthalmologist will discover more cases of myopia and correct them earlier than he will anticipate. All cases of myopia in the upper school should be known, got into glasses, and kept under very careful supervision, especially with the view to levelling up the glasses.

3. The recognition and careful consideration of cases of hypermetropia, and especially before ordering glasses for low hypermetropia, the estimation of the degree of the defect being a primary consideration. Secondly, the substitution of the principle of encouraging the development of the ciliary muscle rather than taking its work from it. No hard and fast rule can, of course, be laid down. Every case must be dealt with on its own merits, including the physical condition of the child, the symptoms produced, and the degree of hypermetropia.

4. As to squint. This problem can never be dealt with satisfactorily until it is, to some extent, at any rate, taken over by the school doctor. Many cases require supervision extending over long periods, and treatment in the infant school is not only carried out in school, e.g., orthoptic treatment. Till this is done thousands of eyes will be let go irretrievably blind.

In conclusion, it is no want of faith in the value of glasses that has prompted these remarks. It is, rather, faith in the enormous value of glasses which makes me urge a more scientific employment of their use and the hope of drawing some attention to the great, and at present sadly neglected, field of eye work in school life.

SOME CLINICAL POINTS ON DIET IN THE TREATMENT OF PULMONARY TUBERCULOSIS. (a)

By C. MUTHU, M.D.,
Chief Physician, Mendi Hills Sanatorium, Walls, Somerset; Consulting Physician to Lady Margaret Hospital, London.

TUBERCULOSIS is chiefly met with in children with disordered nutrition and disturbed metabolism brought about by unhealthy conditions of civilisation. The digestive organs seem to be the first to suffer from civilised life. When the sanatorium treatment was inaugurated in this country some 15 or 16 years ago the treatment consisted
in fresh air and hyper-alimentation. Now a great change has come over for the better in this respect. Generally speaking, consumptive patients at the early and curable stage do not require more food than others. As a rule the open-air treatment together with the regular life led in a sanatorium creates a healthy appetite which requires no compulsion or encouragement. It is impossible to formulate a standard diet suitable to all tuberculous patients, as they differ in age, sex, temperament, height, weight, etc. Diet constituted upon scientific calculation as efficient and satisfactory does not always work out correctly in everyday practice. Man is a living organism and a mere notion cannot be given to the digestive organs concerning the amount of proteins and carbo-hydrate from a given amount of food. The great secret of dieting sanatorium patients lies in using every natural means to create a healthy appetite and if possible avoid all artificial aid in the way of medicine or patent or concentrated foods. I believe in the three meal system. The stomach is the greatest friend of the consumptive. The gastric organs should have four hours’ rest between meals and should not be given as an excuse for breakfast, dinner and supper, except a cup of tea about 4 o’clock. The more rest given to the digestive organs the better and more efficiently will they serve the patient. Over-feeding is both unscientific and injurious. Forced feeding is not necessary in the earlier stages of the disease and is not of much use in the late stages, when the stomach is too enfeebled to digest any food. Many Continental physicians have spoken against the evil effects of over-feeding. (a) In my own experience, over-feeding induces dyspepsia, haemoptysis, dilatation of stomach and intestinal disturbances. Contrary to ordinary experience I find that an excessive meat diet feeds the disease, induces intestinal auto-intoxication, keeps up the temperature and retards the arrest of tuberculosis. A turred tongue, bad taste in the mouth, constipation, headache with slight pyrexia and sleeplessness are symptoms that the patient is having more food than he can digest, and the diet should be cut short. Meat is really the last article of diet and should be given with caution, as I have seen Europeans, Indians and Arabs get cured of tuberculosis on vegetarian and fruit diet. Especially patients with weak digestion should not be over-fed. If after a few days’ trial ordinary meals produce feelings of discomfort food should be cut short and the stomach given rest. If dyspepsia or anorexia still continues it is a good plan to try two meals a day. I have found over and over again that patients who cannot eat are all the better for abstaining from food and then their appetite returns. (b) Another plan is to have a light meal after awhile and then they are able to relish their food after a fast. In fact, fasting is a leaf taken from nature’s book. It is surprising how little women patients eat as compared with men and still gain weight. The secret of successful diet depends more upon attention to economy in diet than by giving way to extravagance. We do not sterilise milk as we used to in the old sanatorium days, as we find our patients thrive better on fresh milk. I am convinced that milk to be nourishing and digestive should not be boiled or sterilised but given in its raw fresh state. I entirely agree with Dr. Vincent, of Manchester, when he said that he could not establish any relation between the consumption of raw milk and the incidence of tuberculosis.

Patients who lose weight have a gain of weight is not always an index to the patient’s improvement in the condition of the lung. I have seen active mischief continue in fat patients and arrest of disease take place in those with slender frames. The gain of weight does not depend upon any particular time of the year. Laugh and grow fat is a scientific truth. A man with a placid temperament gets more nourishment out of a small amount of food than one with an irritable frame of mind. Behind food lies the power of digestion. Over-feeding and behind this again lie the condition of the mind. Worry and anxiety, mental strain and stress interfere with the physiological functions of the stomach and healthy metabolism. Therefore, the sanatorium physician in arranging the diet of the patient should take into consideration the mental condition and temperament, the habits of life and idiosyncrasies, and only by discrimination and individual attention and placing the patient in a happy and cheerful frame of mind can be successfully wage war against tuberculosis. (a) Professor Lawe, Dr. Mouniess, Professor Robie, in The Medical Press and Circular, Sept. 30th, 1908.

ST. THOMAS’S HOSPITAL.

A CASE OF CARCINOMA OF THYROID.—Under the care of Mr. Ender M. Corner.—Operating on a case of simple tumour of the thyroid, Mr. Corner said that there were a few details in operating on this organ. First, the area of excision should be adequately large and after the example of the “collar” incision advocated by Professor Kocher, of Berne. Secondly, there must be no haemorrhage, all vessels being clamped in two places and divided between. Thirdly, the tumour must be “shelled out” as closely as the capsule as possible so as to avoid all injury to the recurrent laryngeal nerve. An injury, such as division, of one recurrent laryngeal nerve would not be noticed at the time, or during the patient’s convalescence. Indeed, the lesion may escape notice until the first sore throat the patient catches after the operation. Then the voice is hoarse and the lesion discovered. There exists no general landmark for this nerve, and it only escapes injury by the surgeon’s keeping close to the tumour or leaving the posterior part of the lobe of the thyroid. Hence Mr. Corner believes that many more are cut than are present recognised. Fourthly, these wounds should be sewn up and not drained; though a big cavity is better drained for 24 hours. Most tumours like this are adenoma, often in part cystic. But it is no uncommon event for the pathologist to find in them carcinomatous change. The prognosis is good in such cases, though in general carcinomata of the thyroid are of bad prognosis. In this connection, he mentioned the case of a woman of about 60 years of age at the time of operation, who was discovered about six years ago with carcinomata of the thyroid. He excised the whole thyroid, but found great difficulty in removing the carcinoma adherent to her trachea. Microscopically the growth was that of the thyroid, but of a more chronic and recumbent form, and had in some cases been adherent to the trachea and picked out first one and later the other recurrent laryngeal nerve. When both of these nerves were paralysed there was bilateral abductor paralysis, and it was necessary for her to wear a tracheotomy tube. In spite of the daily use of thyroid extract the poor woman’s health got worse and worse. Kind people got her into a Home for the Dying. Mr. Corner said he had an authority that she is the only person who has walked out of that Home! With the nursing, feeding, and care the woman got slowly better and

UNITED STATES OF AMERICA.

AMERICAN LEGISLATION TO MINIMISE ILLICIT OPIUM TAKING.

(Continued from our last issue.)

The first step in this was to evade the importation of smoking opium by the Act of February 6th, 1900. But this law has no effect upon the excessive importations of medicinal opium, nor does it prevent traffic between the states of the Union. As a matter of fact, opium is largely smuggled at its lowest sell by the authorities as soon as it passes the Customs House. And as there is no prohibition against manufacturing smoking opium, this matter is left to the individual States, only a minor portion being forbidden this manufacture; and even in them the law is not always effective. This could be easily done through a prohibitive internal revenue tax of, say, a thousand dollars a pound on all smoking opium manufactured, There is mooted such an amendment to an old act of 1890.

The control of interstate traffic is, however, a much more difficult matter, for each State is autonomous, under the constitution of the Union, except in such matters as has been specifically excepted for delegation to the United States Congress. The States are jealous of the encroachments of Federal power, which have been attempted and failed in much more important matters than the regulation of the opium traffic. We are waiting for all the States to pass laws restricting the importation of opium before that traffic be properly controlled. If this is the case, we may look forward to such a scandal as has been presented by the laws for regulating divorce and for the licensing of joint stock companies, where a single State, for the sake of the accruing fees, has connived at and licensed grossly immoral situations in order that its treasury may be enriched by those to whom it pays no account of the fact that other States do not conventionalise, police, or govern adultery. It is only by a law to regulate the interstate traffic in forms of opium that some such procedure could be prevented for a long time.

Since the Act of 1890, little smuggling has been attempted, except at Pacific ports and along the Mexican border. The scope of the Act has been greatly augmented by the action of the Canadian Government; since July, 1908, it has prohibited both the manufacture and importation of opium, which was formerly so extensively smuggled from across the Canadian border. The success of the Act is largely due to the provision that possession of the drug, coupled with evidence to authorize conviction, unless possession can be explained to the jury's satisfaction.

The State of California has already modified its laws for controlling illicit dealing in habit-forming drugs (April 21st, 1909). By this Act the sale of medicinal opium is 17 per cent., less than before, of morphine 27 per cent., of cocaine 40 per cent., and the use of smoking opium has been reduced to a minimum, so much so that its price has risen from $16 to $50. Another effect is that the importation from Asia has decreased, and many Chinese are returning home, as they are unable to obtain the opium to satisfy their cravings. Besides, many addicts are entering the agricultural and sanatorium to attempt to cure this craving. The Physicians and speculators report that an increasing number of smokers believe that opium dens are a thing of the past, thanks to the provision which constitutes the possession of narcotics a crime.

COCAINE.

It is estimated by Dr. Hamilton Wright, one of the United States Opium Commissioners, that at most 20,000 oz. of cocaine are required for surgical purposes in the United States. There are manufactured at least 150,000 oz. This is mainly consumed without medical sanction by habitual users who seeks its narcotic effect. The drug is the most pernicious one used in the Western world, as it drives its consumers to a life of crime which does not hesitate at murder. The negroes of the South have become very fond of it, and it is distributed to them by unscrupulous white dealers, generally through relays of middlemen who sell it in small quantities, very often to othermen, who sell it to the consumers in still smaller quantities. It is very difficult to convict any of the chain; and the profits are enormous, as it can be bought for about $25 and sold for $300. There are generally sold in one or two grain packages for a quarter of a dollar each i.e., a profit of 480 per cent. Whisky is often charged with it and sold in the shebeens of the South. It is claimed that contractors deliberately give it to ignorant negro workmen in order to induce them to furious energy for work. It is claimed, too, that rape by negroes, for which so many have been hanged, is often contributed to by intoxication with cocaine. Its use to corrupt young girls to prostitution is alleged; but there is no doubt that the drug is also extensively penetrating the Army and Navy, and even to the educated element of the population.

TARIFF LAWS.

The new Tariff Act of February, 1909, imposes the following:

Crude opium, not adulterated, with at least 40 per cent. of morphia, 25 per pound. When dried or otherwise prepared, 82 per pound.

Morphia, or other alkaloids of opium and their preparations, for use in medicine, 35 cents per pound.

Cocaine or its derivatives, 85 cents per oz.

Coca leaves, 5 cents per pound.

Liquid preparations of opium, 40 per cent., ad valorem.

FEDERAL LAWS REGARDING COCAINE.

By an Act of March 3th, 1900, the Postmaster-General has power to prevent passage through the mail of cocaine and other dangerous drugs. There is a fine of $1,000,000, or imprisonment for not more than two years, or both, for either offence. The American manufacturers of cocaine asked Congress to place upon its prohibited list, but the prohibitionists in other States. Unscrupulous druggists or physicians may in this way imprint the drug habit in hundreds of people. Moreover, there is nothing to prevent anyone from ordering it from a manufacturer in another State that he desires a narcotic for sale in his own State, where he could not obtain it on account of not being licensed. Only by Federal control of the interstate commerce in narcotics is it possible to reach illicit dealers of this kind.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

GLASGOW.

Sir Donald Macalister in Germany.

Sir Donald Macalister, who has been undergoing the cure at Bad Emms, was, with Lady Macalister and Miss Macalister, before the exiled foreigners who were turned out of that place at very short notice. They were sent under military and police protection to Nassau, and thence to Limburg and Frankfurt. At Frankfurt, Principal Medizin, and "Universitats-Rektor," was placed in charge of a party of seven, consisting of invalids, English ladies and their maids, who had been patients at Emms. He received from the authorities a pass permitmitting them to travel by way of Holland to England. All luggage had to be left behind. The party was forwarded slowly from point to point by military train, as opportunity offered, by way of Coblenz and Cologne. Everywhere military and civil officials, private soldiers and private citizens showed the party the utmost consideration and kindness, and apart from the inevitable hardships of a state of war no incident that could even be described as unpleasant to point out. The Principal was indebted to some generous Germans, previously unknown to him, for advances of money, without which he could not have proceeded on his journey. From Cologne the party, with a large number of English and American fugitives, proceeded to the Rhine by Dutch steamer, thence to Rotterdam, whence they proceeded to Flushing by train and crossed to Folkestone. They had no news of events at home from July 27th until they reached Rotterdam on August 5th.

SPECIAL GRADUATION FOR THE ARMY.

A special final examination in medicine has taken place at Glasgow University for a number of candidates who had completed their course of study and desired to volunteer for active service. It concluded on Saturday, 13th inst., and the 22 candidates assembled about five o'clock on the same day to hear the result. Nineteen, it was announced, had passed. These were immediately marshalled in the Senate Room, seven of them wearing khaki uniform beneath their academic gowns. The degrees of M.B. and Ch.B. were conferred on them by the Vice-Chancellor (Sir Donald Macalister) presiding.

RADUN FOR GLASGOW.

The committee some time ago appointed to secure a central supply of radium for Glasgow and the West of Scotland, have received subscriptions amounting to over £7,300, and the Bellahouston Trustees have promised a donation of £2,000. For three years they will take the expense of custody and administration and afford a proper trial for the scheme, provided the future progress, in the Trustees' opinion, justifies the continuation of the grant. Arrangements have been made for the purchase of 200 milligrams of radium, which will be ample for the committee's requirements in the meantime, and the University authorities have placed a room in the University at the disposal of the Committee. This room is in course of being fitted up as a radiometric laboratory under the supervision of Professor Fredk. Soddy, F.R.S., and on his recommendation a very capable physical chemist has been appointed. Arrangements are in course of being completed by the medical authorities in the city for the treatment of patients by radium.

WAR ITEMS.

Professor Sir William Mac ewen is among those who have been appointed consultants by the Medical Department of the Royal Navy, and who in most instances have been detailed for special duties. Among the 500 first elicited from Glasgow was one which was being spread by a man apparently pretending to be one of the doctors of Stobhill Hospital, Glasgow, to the effect that some Scots Greys were lying wounded in that hospital.

BELFAST.

MEDICAL ARRANGEMENTS IN BELFAST IN CONNECTION WITH THE WAR.

The Corporation Committee of Management of Hospitals and Dispensaries of the City of Belfast has decided to offer to place at the disposal of the military authorities for hospital purposes such accommodation as may be available at the Albert Bridge Road Institute, and the Cemeteries and Parks Committee have placed at the disposal of the authorities the Exhibition Halls of the Daisy. Arrangements may be made available for hospital purposes if necessary. It is also suggested that the latter Committee, associated with the Public Health Committee, might in addition arrange for the provision of volunteer medical and nursing staffs if such be required.

ROYAL VICTORIA HOSPITAL.

The Board of Management of the Royal Victoria Hospital has sent the following telegram to the War Office: "The Royal Victoria Hospital, Belfast, offers fifty beds at once for wounded sailors or soldiers, and a further fifty beds on twenty-four hours' notice." Similar arrangements are being made throughout the province, as in Downpatrick Infirmary and in hospitals in Portrush, Coleraine, and other places. Some of the hospitals in the province of Ulster which had been intended for the use of the Ulster Volunteer Force are temporarily placed at the disposal of the military authorities.

Samaritan Hospital for Women, Belfast.

The General Committee of the above hospital have passed the following resolution: "That the General Committee of the Samaritan Hospital for Women, Belfast, desire that the number of the nursing staff and assistance of the nursing staff and assistance of the hospital be increased by the military authorities, and the practical impossibility of obtaining fully qualified nurses to carry on the work, the Committee feel reluctantly compelled to close the hospital for the present."

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

INFANT MORTALITY.

To the Editor of The Medical Press and Circular.

Sir,—The Executive Committee of the Associations of Infant Consultations and Schools for Mothers asks their co-operation in the Press to point out to all those who have the charge of young infants that many deaths and much illness may be prevented by the observation of a few quite simple principles of mother-craft. Of these principles they cite the following among the most important:

1. To persevere with natural feeding up to the end of the ninth month, or even longer, even though the mother is compelled to go out to work. Employers of female labour are earnestly requested to give nursing mothers opportunities for feeding their babies.

2. To do in those cases in which such opportunities are impossible weaning is by no means necessary. A supplementary feeding of cow's milk will not disagree with the infant and may save the infant's life.

3. That the chief causes of illness among nurses and other babies is irregular and too frequent feeding by day as well as by night: intervals by day should not be less than three hours, and at night a long interval of some six-eight hours should always be provided.

4. Expectant mothers should also seek advice as to their own health, either by consulting their doctors or by attending the schools for mothers.

5. That stimulants are not only unnecessary, but are harmful both to nursing and expectant mothers.

To me as the head of a very large mothers' meeting, where discussion of this question has for many years been kept to the front, it is annoying to see the 4th and 5th clauses without any insistence upon the need for mothers to refrain from dosing themselves or their children with anything excepting with any drug or medicine except some simple laxative like castor oil, and never to do even this without
full confidence that at any rate she is doing no harm. Infants—be they advertised in every cheap paper; their sale must be enormous, and can be found in the majority of poor homes. They help to kill and directly kill a vast number of babies yearly. This ought to be explained to mothers, and they should be implored to send for their babies or themselves to court. The mothers can be made to understand that the frequent show of pain is mostly due to the load of indigestible food it carries in its beak, which is a proper treatment for proper feeding. After clearing out the load from the bowels, and they can be made to understand that when anodyne quack medicines are given the pain may be put an end to for a time, but the form of torture continues, and the disorder advances towards death. The infamous wretches who live on quackery, unhappily at present not amenable to the law, hire clever scribes to indite their lying statements which entrap their simple victims; and the newspapers that set themselves up as guardians of the people put them in for paltry gain in the guise of editorial matter, knowing that thus they are participating in crime. I have noticed in the Lancet a few paragraphs in which it forms one of the biggest scandals of the day, especially as the great bulk of leading papers set the example. I am, sir, yours truly,

A Doctor's Wife.

Manchester.

FORCIBLE FEEDING.

To the Editor of The Medical Press and Circular.

Sir,—Dr. Clement Sers says "forcible feeding" is a "medico-legal question," that is to say, it is a question of the legal aspect of a medical act. Let us, therefore, look at it from these two points of view.

(a) Medical Aspect.—Forcible feeding is certainly not employed, as Dr. Sers asserts it is, to keep militant, hunger-striking Suffragists alive, because if it were then all such prisoners, including Mrs. Pankhurst, would be forcibly fed.

In fact some prisoners are fed and others are not, by favour of the authorities. Of course, Dr. Sers no doubt knows the Home Secretary has given up the miserable farce of calling forcible feeding "medical treatment," and that Mr. McKenna in the House of Commons even said it was a "most objectionable practice.

Clearly then, Dr. Sers must entirely alter his view of forcible feeding, and he will possibly agree that, as was indicated by the Home Secretary in the House of Commons, it is really a punitive procedure or in plain English a form of torture. That this is so is also shown by the fact that, though medical treatment (real) is given in all prisons, two prisons have been detailed for this particular purpose—namely, Holloway for England and Perth for Scotland. This leads naturally to the other aspect of the matter which we may now glance at.

(b) Legal Aspect.—Forcible feeding, though not "medical treatment," as we have just seen, is nevertheless a criminal act. Doubtless Dr. Sers would meet this point by saying that as prison doctors are sworn in as constables they are in the position of any prison warden who may be ordered to flog or otherwise punish by torture a prisoner, and the law may be true, and it often has been asserted, I have never been able to see that this special attribute of a prison doctor's work was compatible with the honourable position of being a member of our profession.

Perhaps Dr. Sers may be able to suggest how forcible feeding as practised in our prisons is compatible either with British principles of equal justice to all prisoners or with the humane ethics of medical practice.

The last two paragraphs of Dr. Sers' letter are not germane to the issue. I have shown many times since the Leighe case, five years ago, that the attempts of anti-suffragists to crush by brutality and force the movement for universal suffrage only creates outcries. Therefore, Dr. Sers must ask the anti-suffragists to find an answer to this question of forcibly feeding and that monstrous failure the Cat and Mouse Act are not answers.

I am, Sir, yours truly,

Victor Horley.

25, Cavendish Square, London, W.

August 10th.

THE INFECTIVITY OF CANCER.

To the Editor of The Medical Press and Circular.

Sir,—Although I have no desire to attempt to discuss this question from a scientific point of view, I am in entire agreement with you that the pernicious and one-sided attitude of the late Press in disseminating these (presumably) cancer "scare" amongst the general public; nevertheless I have good reason to believe that many medical men were unawakened—at any rate, until quite recently—to the infectivity of cancer, and it is only fair to state that a few years ago I wrote to your contemporary the Lancet on this very question, and, although my letter was not published, I immediately acknowledged it, and stated that his experience was not in accordance with mine. In case, however, any of your readers may still entertain doubts, I presume to offer a few facts and figures, although evidence operates differently on different thinkers, but I do so, if possible, to influence them, and probably to many others, that, inasmuch as in the vast majority of instances medical men cannot be found who have treated or attended two cases of cancer in any one community simultaneously, this affords sufficient and considered evidence, to my thinking, that this disease is not infectious, for the simple reason that the same cannot be said of any other infectious or even contagious disease, either syphilitic or parasitic. Having a special interest in the subject, I recently purchased at a second-hand dealer's an old book entitled "The Nature and Treatment of Cancer," by Walter Hayle Walshe, M.D., Physician to University College Hospital, London, which, which seems to coincide with what I have just stated. Dr. Walshe's views are briefly as follows:—"The opinion that cancer ranks amongst diseases transmissible from individual to individual by means of an infectious principle is not even at the present day without its supporter... Of the thousands of individuals engaged in attendance on cancerous persons, how many become similarly affected? Were the disease transmissible, would it not have been natural for doctors or their two or three years the bed of their cancerous wives, being seized with the malady, yet a single authentic instance of such an occurrence remains to be recorded." Yours etc.,

Clement H. Sers, M.R.C.S.

5, Chancotbury Road, Hove.

REVIEWS OF BOOKS.

ACUTE ABDOMINAL DISEASES. (2)

Since the appearance of Lejars' "Urgent Surgery" we have not met with a clearer description of abdominal emergencies and their treatment than in the present work. The teaching is sound all through and eminently reasonable. We welcome the collaboration of physician and surgeon, for acute abdominal diseases come under treatment by all members of the profession, and it is necessary to set forth every point of view. We are glad to see that immediate operation is advocated in acute appendicitis, and that the various complications which may be met with on opening the abdomen are adequately considered. The chapter on hernia is admirable; we would like to see more exact details given with regard to the treat-
of herina en glitate. There are operations for this condition, after which there is no necessity for the patient to wear a truss, and they require very little more time for their performance than the one described. Every author seems to be writing a preliminary chapter on the anatomy of the part under discussion, but we consider that if the surgeon about to operate does not already know instinctively the anatomical arrangements with which he has to deal, he had better ask the case over to somebody who does. We do not blame a surgeon for refreshing his anatomical knowledge before an operation, but we think that he would scarcely require to seek the position of the ascending colon on the course of the deep epigastric artery. If a chapter on anatomy is necessary it should deal very fully with the subject or should be confined to special details which the author has found to be of special importance. We would suggest that every surgeon who reads the last chapter on the diseases which simulate acute abdominal lesions; we are afraid that the possibility of their presence sometimes occurs to the surgeon after he has opened the abdomen. This book is a good one, and we would recommend it to everyone who is beginning the practice of surgery, and it would do the most experienced surgeon no harm to consult its pages.

**Therapeutic Value of the Potato.** (a)

This monograph is based on an article contributed by the author of the *Lancet* of April 11, 1914, and it deals with his researches into the therapeutics of the common potato. He finds two outstanding properties in raw potato-juice. First, a prompt relief from pain, and, second, a rapid absorption of fluid in cases of synovitis. At first sight the potato would not seem likely to possess any great curative effect. No alkaloid is present, and potassium salts are the chief ingredient. Anyway, in the author's hands it gave results, such as to press the juice out of the tubers, remove the starch and nitrogenous matter and concentrate with heat till an extract five times the strength of the juice is obtained. This is the *extract solium liquidam*.

An ointment, a liniment, and a plaster are made, and the sterilised extract is also put up in ampoules. Dr. Howard gives details of his methods and results, and finds that great benefit results from the use of his preparations in synovitis, gout, lumbago, rheumatism, and bruises. We hope others will be equally successful.

**Lourdes** (b)

This volume provides an account of the focus of pilgrimage which so conspicuously attracts both the exalted priest and the scientific curiously. For this man of very much emancipated generation. It is sure to be widely read, as the general attitude of the public—wide in all its conflicting views—and the very exceptional abilities of the author must combine towards the total effect of concentrating attention on a document of which the very title suggests so much of life and inspiration—and contradiction. Mr. Belloc very justly represents the *status quo* in his interesting and well thought-out preface: "Lourdes means a meeting or emotional, political, and religious theory, for which that word stands."

And we believe that we are fairly accurate in our suggestion that Lourdes may also be taken as the standard of the militant champions of the claims of the spiritual part of the human organism in opposition to the unquestionably well-worked ones of the material substratum. We will venture an opinion that Mr. Belloc has a visible as well as tangible foundation of truth for his statement that: "The men who control our Press today are as ignorant as they are brutalised by intrigue and avarice, and blinded by these and other appetites to reality and to proportion." Those who have been in intimate contact throughout with the limits of the intellectual media of the past quarter of a century must—if quite candid in the expression of their views—admit that the above presentation is by no means an unfair one of at least one profile view of the general mass of our political and social developments and engineered, as it has come to be, by the grossest mechanical materialism. Without attempting to formulate any opinion regarding the mutual relationship of mind and matter, and attempting to refute the oscillating claims for relative ascendency—which are advanced by self-styled advocates, we would just point out to the inquiring reader that the continuous influence of mind over matter—for the spiritual and emotional over this chemical and gravitational—are being continually ignored (whether unconsciously or otherwise) by persons who have every day presented to them examples of the sudden blanching of fear, the raptant glow of hope, and the ashens of hopeless sorrow with the invisible microbe always lying in ambush. The self-satisfied materialist may also be invited to ponder over the suggestion that it is to the attempt to suppress the emotional aspect of human nature and to eradicate all vital phenomena to the dictates of the rule of three that misguided humanity now owes the evolution of the nihilist and the sufrafuge. The object lesson of Lourdes may be read in very varied lights.

**Cancer of the Rectum.** (a)

For several reasons this book is noteworthy, first, because it gives the experience of a personal expansion; the surgeon who must be regarded as one of the founders of the modern treatment of rectal cancer; second, because the author's conclusions are based on a very great number of cases; and third, because the book abounds in practical details and lessons of treatment. The comfortable way of applying a T-shaped bandage is described. The book is of interest with regard to the history of the subject as it concludes with summarised conclusions written in 1876. We are more in accord with Mr. Cripps' treatment than with his pathology. The relationship described between epithelial cells and leucocytes is puzzling in the light of modern pathology. Neither do we agree with him as to the relative uselessness of the sigmoidoscope. With patience this instrument is usually a useful aid and sometimes invaluable. We find only three pages devoted to the combined method of operative and irradiating treatment. The book, however, does not pretend to deal exhaustively with the subject; it is simply a record of personal experiences in this branch of surgery, and as such is valuable.

**Applied Psychology.** (b)

The present readable and handy booklet furnishes an important as well as interesting item of testimony to the quality and prevalence of the methods and attainments of our motile democracy in its present transient stage of progressive evolution. We have here the obvious aim at popularisation of one of the most intricate subjects of human investigation, and the suggested hope of making the same available for the less learned—the lessons—lessons being presented in apparently clear and self-revealing sentences and paragraphs; and skimming, if not exactly penetrating, the receptacles of thought and displaying to view the weapons used in its arsenal. And the result obtained is what would have been anticipated by those who know something about these matters: the diction and phraseology are usually good—as such things go; the statements and style are free of the same style and the introductory "Introduction" is one of the most readable and illuminating sections of the text; and the general standpoint is apparently that of omniscient vision combined with the "total internal reflection" which veilingly and smoothly reflects all intellectual (6).

light in the direction along which their luminosity is desired. The average educated voter will have learned a good deal—though, we feel sure, not nearly so much as he will feel disposed to think—by looking down the closely read volume, that he has securely and permanently mastered. We incline to think that this compendium of things psychological and philosophical would have pleased the great Lord Chancellor Ilchester and his satellites. At the same time, the level of Herbert Spencer—an estimate which would be regarded by most contemporary writers as very high praise. It presents a contributory item in the movement of procrustean standardisation, which seems to aim at bringing all human intellects to the same uniform level, in the coming generation, all over the whole area of civilisation. The result will hardly prove a brilliant one to persons of our way of thinking: the amateurs will be sufficiently numerous to crowd out—almost to suffocate, or actually crush—the experts, whose dwindling numbers and opportunities will eventually leave the psychology and most other high-class intellectual work to be begun all over again. Meanwhile, for those who like this sort of thing, the booklet before us will, we think, prove acceptable.

**LUXOR AS A HEALTH RESORT.**

This is the second edition of a booklet of which the first issue appeared just a year ago. The date thus tells the tale of public appreciation. The name of Luxor calls up the glass picture, before the imagination of the historian, the ethnologist, the religious, and the soldier, as well as one of discriminating attraction before that of the meteorologist and the exultant of modern sophistication. At the same time the whole remains associated with the earliest extinct annals of king-craft and of priest-craft, with the most pronounced peculiarities of climate above and of terrestrial productivity below, as well as with the many recorded records of battlefield achievement and of political chicanery: of the quasi-miraculous conquests of the greatest of warriors and of the greatest of engineers.

**PROGNOSIS IN PULMONARY TUBERCULOSIS.**

This large octavo volume is thoroughly representative of the zeal, honesty and tenacity of purpose which carries the earnest citizen of the Vaterland through so many an intellectual hurdle. It is the highest quality. No available source of enlightenment—of all the beams and scintillations, old and new—that has been hitherto focussed on the dark places of the origin and destruction of the great and almost last vestiges of tuberculosis has been able to have escaped the researches of our authors. And we are glad to observe that some of the most respectfully mentioned conclusions of the endless list of authorities quoted in the present encyclopaedic volume are the old and uncontradictable observations and suggestions which are to be found embodied or outlined in the aphoristic expressions of clinical experience that date back to the days of the inspired "Father of Medicine" himself, or even earlier. Thus we find it, Gunzburg, always discussing the subject in 1861, informed his readers that the "sanguinische, plethorische, lebhafte, reizhafte Subjekte sind mehr gefährdet als solche von eher kühler Natur." Koranji expressed the opinion that: "Ruhianges Temperament, Besonnenheit, starker Wille, um schädlichen Einwirkungen auszuweichen, verbessern die Ausichten; sentimentale, bitzige, zynophile Natur verschlechtert die Prognose;'' and so forth. And thus it will go, Gunzburg, always discussing the subject in 1861, informed his readers that the "sanguinische, plethorische, lebhafte, reizhafte Subjekte sind mehr gefährdet als solche von eher kühler Natur." Koranji expressed the opinion that: "Ruhianges Temperament, Besonnenheit, starker Wille, um schädlichen Einwirkungen auszuweichen, verbessern die Ausichten; sentimentale, bitzige, zynophile Natur verschlechtert die Prognose;'' and so forth.

**INTERNATIONAL CLINICS.**

The present volume is on a par with other numbers of this well-known quarterly. It contains eighteen articles under the headings of Diagnosis and Treatment, Medicine, Surgery, Neurology, and Enginics. Rather mere prominence than usual is given to psychotherapy. All the articles are well up to the standard that the editor and publishers have led us to expect, and the illustrations to such articles as are illustrated are good.

**SCHOOL LIGHTING.**

This monograph is issued by the Medical Officers of Schools and is patronised by the School Board, and originally read. The question of both the daylight and the artificial lighting of rooms where numbers of children are to work is one of great importance. Till 1863, when Cohn made his investigations with reading type, no notice had been taken of the matter. Cohn concluded that the window area in every schoolroom should be at least one-fifth of the floor area. Various other authorities have increased the proportion of window area. Ker and others have shown that a window area actually greater than that of the floor. The amount of light can be measured by various angular calculations made from the worst lit desk as well as by Dr. Ker's instrument somewhat on the lines of a scientific camera, which can be placed on any desk and the light value immediately read off. The direction of the illumination as well as its intensity has to be considered. As we are right-handers our light must fall from the right, with artificial shadows while writing. Cross shadows and ventilation has to be taken into account, as well as the whole system of artificial lighting. In this case the chief bacteriological pathology, and with the varied clinical adaptations of the therapeutic qualities of tuberculin notwithstanding.

**PHYSIOLOGIE NORMALE ET PATHOLOGIQUE DES REINS.**

This beautifully printed octavo contains a comprehensive summary of the results which the researches of recent years have contributed towards the illumination of this domain of clinical knowledge. Indeed, it represents in its most luminous and intelligible aspect grade of achievement that has been found attainable in the characteristically "modernist" attempt to reduce the principal function of an organ of the living mechanism to the definite expression of a single element such as a chemical, while inevitably suggesting the halophilic-epigraphic laws that of correspondingly definable limiting powers may in the future be proved to control the respective functions of the various other glands of the human economy. The terms expressive of renal filtration and permeability have been shown to correspond but very remotely to expressions of actual fact. The study of the modified functions of diseased kidneys in the Hospital Nephrology is especially pointed out, and the chloruro-constants of secretion, especially the former; and the fact that the Académie des Sciences has this year awarded the "prix Monthyon" to M. Ambord, the highest distinction awarded by his country as a reward for his research on the renal and urinary physiology, in the manner in which the issue of the quality of his work. We accordingly have no hesitation in recommending the present volume to the attention of every earnest practising physician. The quantity of new and enlightening material here collected and lucidly displayed is too large, and its quality far too high, to make any attempt at critical detail either logically just or scientifically desirable. The contents of this volume should be assimilated in toto; we will guarantee their nutritive property.
difficulty is to have enough light without glare. Black boards are a frequent source of trouble, as it is often almost impossible to place them so that the writing is visible without strain by some of the roomful of children. Dr. Nasch has compressed a great deal of information into a small compass, and his book will be of the greatest value to any medical man who may be concerned with the designing of a school or similar building.

THE STUDY OF RÖNTGEN RAYS. (a)

This well-printed and well-illustrated actavo is a good introductory text-book of the very curiously fascinating, as well as instructive and clinically useful and research. It is written by a skilled expert in the domain of physical science, and in the present labyrinthine structure of one of the profoundest strata of that vast and puzzling edifice, the exposition and corroborative testimony of an expert guide is absolutely necessary. It should be at every student's disposal at all times.

It is a very valuable book, and should be recommended to all who are concerned with the teaching of the subject. It is well printed, and the illustrations are in perfect accord with the peculiar nature of the subject with which it deals. The illustrations and diagrams are very well selected and clearly printed, so that their presence adds greatly to the power of a skilfully written text. The small volume will have a wide distribution, as it seems to us to have all the qualities desirable for an introduction to the larger clinical manuals, and to the clinical practice in which Röntgen rays now take so very important a part.

INDUCED CELL PRODUCTION. (b)

Where would the sciences of physiology and pathology now stand if the amoeba had never been discovered, or created, or evolved? Echo, of course, answers—but we can all offer a probably approximate guess. The key of the doorway and pathway to all those illuminating researches is furnished by "a working hypothesis that normal cell production and benign tumours are caused by certain reagents called auxetics, such as tyrosin, creatin, etc., and that cancerous tumours are caused by a mixture of auxetics with another group of substances, called kinetics or augmenters, such as choline and cadaverine." The volume before us deals with a very great number of physiological and pathological conditions, and their possible bearing upon more important collateral movements and facts. We do not think that a majority of the questions opened have been finally answered—it is not possible, and we by no means think it should be just yet—but a great deal of new light is being continuously produced and shed on many dark recesses of the vast domain of biology. We congratulate the authors on the results already achieved, and the hope that they may go on with their good work in the increasing illumination of their own widening and deepening experience.

MANUEL DE CYSTOSCOPIE. (c)

This volume forms another addition to the valuable series of manuals on special medical and surgical subjects which M. Gittler has recently been placing before the students and practitioners of the medical art. The text and illustrations (of which there are 320—including some excellent ones "hors du texte") collectively constitute a very prominent example of the wonderful skill which has been attained during the past few decades in the adaptation of modern mechanical inventions to the treatment of so many lesions of the human organism, and the presenting illumination with which the imponderable side-lights of modern scientific invention have projected on the many dark places of the respective domains of diagnosis and therapeutics.

As Professor Legueu observes in his preface to the present volume, "Every science demands a prolonged period of preparation from the would-be expert, and cysctoscopy has proved to be no exception to that rule. But the lines of such necessarily laborious training are now so clearly laid down in the manuals of clinical illumination which are the unavoidable sine qua non, as well as of luminosity and approximate completeness of detail. The author himself comments on the frequency with which he used to be asked by anxious pupils aspiring to expert knowledge: What is the bath, E. H. Terry, L. B. Clarke, W. G. Maw, H. T. Roberts, M. dos Santos, and J. A. Watson.

The National University of Ireland.

The Senate met on Wednesday, August 19th, 1914. The Senate directed that in view of the present national crisis, and in order to facilitate the immediate entry of the majority of candidates for medical service in the Navy or in the Army, a special examination for the M.B., B.Ch., B.A.O. degrees shall be held, beginning on Tuesday, August 24th, 1914.

The written papers will be held at University College, Dublin; University College, Cork; and University College, Galway, to students of these Colleges respectively; but the clinical examination will be held only at University College, Dublin.

The candidates eligible to enter for such special examination shall be (a) those who have already entered for the ordinary autumn examination for the M.B., B.Ch., B.A.O. Degrees; (b) those whose forms of application for admission to the special examination for the M.B., B.Ch., B.A.O. Degrees, accompanied by fee and certificates, shall have been received by the Registrar at the National University of Ireland, 40, Merrion Square, Dublin, at or before 12 noon on Monday, August 24th, 1914. All candidates will be required to present themselves in either (a) all subjects of the examination, or (b), if they have already passed in any part of the examination, in the part necessary to complete the examination.

No late fee will be payable in connection with this special examination.

Intending candidates are requested to give the earliest possible notification of their intention of presenting themselves for the special examination to the Registrar, the National University of Ireland, 40, Merrion Square, Dublin.

The Senate adjourned.

Plague in Hong-Kong.

It is reported that five cases of plague occurred in Hong-Kong during the week ending August 15th. The number of deaths was also five.

Society of Apothecaries of London.

The following candidates, having passed the necessary examinations, have been granted the L.S.A. Diploma of the Society entitling them to practise Medicine, Surgery, and Midwifery—:

Summary of Recent Medical Literature

Clinical Significance of Sarcomatous Change in Uterine Fibromyoma.—Graze (Brit. Jnl. Obst., xxxiv., 3) in a study of 250 cases of uterine and cervical fibromyoma, found twelve showing sarcomatous changes in various types. In most instances the myoma were multiple with but one focus of sarcomatous change, and only one Sarcoma was found in two interstitial tumours. Only one case was a solitary fibroid. Sarcoma which develops in myoma may arise from various structures in the fibroids. The clinical history of the sarcomatous cases shows nothing characteristic. From the ages of the patients, sarcomatous change appears to be most frequent about the time of the menopause. It is in these cases that the greatest care must be exercised. To a great extent the Rontgen-ray treatment is most applicable in the cases where the frequency of sarcomatous change is highest, and also in that type of tumour in which the malignant change is relatively common, and for this reason is attended with the risk of overlooking a sarcoma.

Treatment of Retro-displacements of the Uterus.—Worrall (Jull. Obs. and Gyn. Brit. Emp., xxxv., 3) considers the most common cause of retro-displacement to be pregnancy which has ended spontaneously and death from the improper mode of living, especially during the developmental period of life. In considering the treatment, it is divided into purely hygienic, manipulative, mechanical (pessary), and operative. The first is considered worthy of trial. The others, except operability, are absolutely condemned. The numerous methods of treatment by operation are not considered except to object to the fixation or suspension of the uterus by either the anterior or posterior surfaces. The author is strongly in favour of suspending the uterus by a small portion of its surface immediately behind the line of junction of the tubes. He has not found any dystocia to follow in subsequent labours, and has had a good percentage of cures in the cases he has been able to follow up.

A Method of Sterilising and Storing Catgut.—Barlett (Surg., Gyn. and Obst., xviii., 5) advises dividing the outer strands into four equal lengths, and coiling them into rings about 1½ inches in diameter. These coils are then strung on a thread. The catgut is then dried in a dry steriliser for four hours at 80°, 90°, 100°, and 110° Centigrade. The catgut is immediately placed in liquid alcohol, where it is kept till perfectly clear, which takes a few hours, but it may be left for ten or twelve hours. The vessel containing the oil should be lined with thin paper. The oil should be left at a stated temperature being raised during one hour to 160° Centigrade and maintained the same for four hours. The put is then lifted out of the oil, allowed to drip, and then dropped into a solution of iodine in methyl alcohol, 1 part to 100 to 1 in 200, according to the size of the cutgut from No. 00 to No. 4, and is ready for use in a few hours.

Abdominal Caeasarain Section for Eclampsia.—Peterson (Amr. Jnl. Obst., Lxxx., 6), from the study of 500 cases collected from numerous operators, concludes that the maternal mortality in the five years previous to 1913 has been reduced to half that of former times. The mortality of 45.7 per cent. of the cases, is lowered by technique and selection of cases, as shown by the thirteen operators having the largest number of cases and a mortality of 18.68 per cent., and when moribund and septic cases are excluded from these the mortality is 13.15 per cent. The effects of the poison may be so great that the emptying of the uterus may not prevent death, which is reduced considerably even when they cease the recovery of the patient is not certain. Operative treatment of eclampsia has never been given a fair trial. To do this the uterus should be explored promptly after the first convulsion. This is shown by the fact that the cases which were operated upon after from one to five convulsions, and where no attempts at delivery were made below, gave a death-rate of 15 per cent. The greater the number of convulsions the greater the fatal mortality. The two mortalities are greater in multiparae than primiparae, and also in proportion to the age of the patient. Any condition which makes delivery by the natural methods difficult may be an indication for abdominal Cæsarean section.

Intramuscular Injections of Antitoxin in the Treatment of Diphtheria.—Rolleston and Macleod (Brit. Jnl. of Diseases, 21st of July, 1914) give an experience of this method of using diphtheria antitoxin. The paper is based on their experience during the last six months at the Grove Hospital, where intramuscular injections were frequently supplemented by more rapid injections of antitoxin. In all 412 injections were given to 339 patients, whose ages varied between two weeks and thirty-seven years; only 35 patients, however, were above the age of fifteen years. Of these 339 patients 43 died, or a mortality of 12.7 per cent., which is the following day, by excluding three patients who died within twenty-four hours of admission to the hospital. Patients with severe faucial diphtheria received from 16,000 to 20,000 units of antitoxin on admission, and usually the same or sometimes a smaller dose was repeated if necessary on one or two of the following days. Patients with moderate faucial diphtheria received from 8,000 to 12,000 units on admission, and sometimes a smaller dose was repeated. In spite of the large doses of antitoxin used the frequency of rashes and other serum phenomena was less than usual. From their experience the writers draw the following conclusions: Intramuscular injection, preferably in the vastus externus, preserves the antitoxin and other methods of administration of antitoxin in the treatment of diphtheria for the following reasons: (1) It is quite as simple as the subcutaneous method, ensures much more rapid absorption, is less painful, and, consequently little if any toxemia, received by the intramuscular route is shown, not by the effect on the faucial or laryngeal process, but by the lesser incidence of paralysis, especially of a severe kind.

The Action of Chloroform on the Blood.—Bean (The Australasian Med. Gazette, June 6th, 1914) records some experiments which he undertook to test the statements made by Gill as to the action of chloroform on the blood. Gill has asserted that chloroform vapour when
presented to the blood takes the oxygen from the red blood corpuscles, and becomes itself oxidised into inert products, and that the resulting anaesthesia is due to oxygen starvation of the brain, since the chloroform uses up the oxygen of the blood in its own oxidation. Bell states that he has been unable to reproduce Gill's results, and his experience compels him to adopt a different interpretation of the action of chloroform vapour on the blood. He believes chloroform is particularly active on the lower parts of the brain, and that killing it, in higher percentages quickly laking it. He believes that chloroform, when used in the minimal doses necessary for the production of surgical anaesthesia, remains confined to the lower parts of the brain and does not invade the higher regions. He believes that the chloroform in the blood causes an oxygen starvation of the tissues and brain by combining with the red blood corpuscles and temporarily suspending, or at any rate, lessening, their power of taking up oxygen and handing it on to the tissues.

K.

MEDICAL WAR ITEMS.

It is reported that cholera has already made its appearance in the Servian and Austrian armies.

The magnificent buildings of Birmingham University are being used by the British Army, and are the largest military hospital in the country at a cost of £10,000.

The Council of the League of Mercy have resolved to use their organisation to collect funds for hospital treatment for the sick and wounded in the offices and on the premises of Messrs. Urwin, Strand, W.C.

Dr. Kendall, Secretary of the Edinburgh University Club in New York, to-day offered a hospital unit to the Canadian Government on behalf of the graduates of Edinburgh resident in the United States.

The Oxo Company have given one ton of Oxo (£70) to the Prince of Wales' National Relief Fund, and undertaken to store it free of charge, and pay carriage on it in small or large quantities as ordered off.

In consequence of the war, and for the convenience of candidates who are desirous of qualifying for medical appointments in His Majesty's service, the Society of Apothecaries of London will hold a special examination, commencing Monday, the 31st inst., for the diploma in medicine and surgery granted by the society. Full particulars may be obtained upon application to the Secretary, Water Lane, Blackfriars, E.C.

Sir Donald Macalister, Principal of Glasgow University, wishes it to be known that the University will do what it can to safeguard the academic interests of the country, and will call its local duties.

The authorities whom he has been able to consult agree with him in recommending that to such students every consideration should be extended which the Ordnances will permit. In relation to attendance upon courses of instruction, to duration of study, to periods of notice required, and the like, account will be taken of a student's absence on military duty; so as, if possible, to ensure that his graduation shall not be unduly delayed.

The Royal Colleges of Physicians and Surgeons of England having regard to the exigencies of the war, have decided to hold a special final examination commencing on September 8th, to which candidates will be admitted under the following conditions:—(1) All candidates who would be eligible for admission to the October examination shall be considered admissible to the special examination in September; (2) Candidates who were referred for three months at the July examination will be admissible to the special examination in September without producing additional examination; (3) Candidates who fail at the special September examination may be admitted to re-examination in October by resolution of the examiners on consideration of the standard attained by them. Candidates who fail at the special examination in September if they have completed the courses of study required for that part, without having necessarily completed the whole curriculum, under the conditions of the old regulations, but they will be required to have attended all the courses prescribed by the regulations before completing the examination.

The National Relief Fund.

Dear Sir,—The Committee are glad to hear of the widespread and admirable arrangements which have been made by the Daily Express for systematic collection, and note with pleasure the names of the important firms who have contributed to help you. They trust that these efforts on the part of the Daily Express will lead to a substantial addition to the National Relief Fund.

Yours faithfully,

C. Arthur Pearson.

York House,
St. James' Palace, S.W.

August 17th, 1914.

The above letter refers to a League which has been organised to enable those to contribute shillings, to the Prince of Wales' Fund, who are unable to afford pounds. Many people unable to give a large amount in one sum will gladly give a shilling a week. Long time has been devoted to deserving a cause as the relief of the families of British soldiers and sailors and the alleviation of distress among the working classes, many of whom have been thrown out of work by a war which will do little to the date of the British Empire.

A shilling may be sent each week, or five or ten shillings can be sent in advance. A receipt will be sent for the first contribution, but afterwards, in order to save expense, so long as the shillings are received regularly, no further communications will be made. All sums of five shillings and over will, however, be acknowledged whenever received.

The name of every member of the League will be inscribed on a tablet at Home Office, and those who subscribe a minimum of 10s. will receive certificates, issued by the Prince of Wales, which will also be receipts for the total amount they have subscribed.

Now is the time to show your patriotism by helping the families of those who are defending your homes. Join at once and send your shillings.

Employers can greatly assist the League by encouraging their staffs to join and by arranging for one member to act as collector and to forward the contributions in one sum each week. Printed forms will gladly be sent on application to any employers who adopt this suggestion.

All communications and subscriptions should be addressed to J. W. Urwin, Esq., Hon. Secretary, Prince of Wales' National Relief Fund Shilling League, 60 Victoria Street, Westminster, London, S.W.

PRINCE OF WALES' RELIEF FUND, SHILLING LEAGUE.

I herewith enclose unpaid shillings for the above League for ......... weeks. I will give a shilling a week to the Fund, if possible, every week until peace is declared. I will try to get ...... new members.

Address: ......

Subscriptions: the sum of Rs......

Date: ......

NOTICES TO CORRESPONDENTS, &c.

Subscriptions may commence at any date, but the two volumes each year are published in January and July. The names of the subscribers are printed in small capitals under the heading: "Reader," "Subscriber," "Old Subscriber," etc. Any subscription not accompanied by the sum required will be returned. The subscription rates are: £5 per annum, £10 per annum, and £5 per month. All communications should be addressed to the Editor of the Daily Express, 60 Victoria Street, Westminster, London, S.W. Prices are 1s. 6d. for the weekly edition, and 2s. 6d. for the daily edition.
HAVE Low from—causes, asserts of typhoid; M. B. Glaso. The rubbish per hour, to Dr. and Mrs. N. T. Bond—a son.

Elpick.—On August 15th, at 1 Carlton Hill, N.W., the wife of George J. F. Elpich, M.D., M.R.C.S., L.R.C.P., of a daughter.

Gibson,—On August 15th, at the Corner House, Breatwood, Essex, the wife of A. J. Gibson, M.B., B.S., of a daughter.

Kemp.—On August 17th, at Jesmond, the wife of Major W. H. Kemp, J.M.O., of a son.

Matthews.—On August 22nd, at "The Limes," Lower Gornal, Stourbridge, Worcestershire, the wife of Mr. Matthews—a daughter.

Milne—On August 17th, at Manchester Old Road, Middleton, the wife of Miss Milne, M.B., M.R.C.S., of a son.

Morrison Davies—On August 23rd, at 85 New Canvendish Street, W., the wife of H. Morrison Davies, of a daughter.

Reynolds—On August 15th, at 18 Park Crescent, W., the wife of Dr. Edward G. Reynolds—a daughter.

Smith—On August 22nd, at Low Bank, Queen's Drive, Mosley Hall, near Stockport, the wife of Mr. Smith—a daughter.

Stam—On August 15th, at 63 High Road, Streatham, S.W., to Dr. and Mrs. Louis Stam—a daughter.

Wilson—On August 16th, at 96, Jesmond Road, Newcastle-on-Tyne, the wife of Frank Wilson, M.B., of a daughter.

Horton Infirmary, Banbury.—House Surgeon Salary £120 per annum, with board and residence in the Infirmary. Applications to E. Lamby Fisher, Hon., Secretary, Horton Infirmary, Banbury.

Brighton General and Eye Hospital, Church Street, Queen's Road, Brighton.—Applications to Mr. E. W. Pilbeam.

National Infirmary and Dispensary, Assistant Resident Surgeon, Salary £180 per annum, with apartments (not board), attendance, light, and fuel. Applications to C. Cheeiman, Secretary, 12 Low Pavements, Nottingham.

Manchester Northern Hospital for Women and Children, Park Place, Cheetham Hill Road.—House Surgeon Salary £120 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 38 Burton Arode, Manchester.

Royal Albert Hospital, Devonport.—House Surgeon Salary £120 per annum, with board and laundry. Applications to the Chairman of theSelection Committee, Royal Albert Hospital, Devonport.

Appointments.

Holland, Earnest, M.D., M.R.C.P.Lond., F.R.C.S.Eng., Assistant Obstetric Physician to King's College Hospital.

White, Albert, M.R.C.S., L.R.C.P., L.R.C.P.I., Honorary Medical Officer, Public Vaccinator and Medical Officer for the Gloucestershire District of the Hay Board of Guardians.

The Medical Officer in chief, Military Wing, Royal Flying Corps, Farnborough, Certifying Surgeon under the Factory and Workshop Acts for the Farnborough No. 2 District of the County of Hants.

BIRTHS.

BESWICK.—On August 14th, at 72 Lower Raglan Street, Dublin, the wife of Charles B. Beswick, M.D., F.R.C.S., of a son.

Boox.—On August 22nd, at 29 Anerley Road, South Norwood, to Dr. and Mrs. N. T. Bond.—a son.

ELPICK.—On August 15th, at 1 Carlton Hill, N.W., the wife of George J. F. Elpich, M.D., M.R.C.S., L.R.C.P., of a daughter.

GIBSON.—On August 18th, at the Corner House, Breatwood, Essex, the wife of A. J. Gibson, M.B., B.S., of a daughter.

KEMP.—On August 17th, at Jesmond, the wife of Major W. H. Kemp, J.M.O., of a son.

MATTHEWS.—On August 22nd, at "The Limes," Lower Gornal, Stourbridge, Worcestershire, the wife of Mr. Matthews.—a daughter.

MILNE.—On August 17th, at Manchester Old Road, Middleton, the wife of Miss Milne, M.B., M.R.C.S., of a son.

Morrison Davies.—On August 23rd, at 85 New Cavendish Street, W., the wife of H. Morrison Davies, of a daughter.

REYNOLDS.—On August 15th, at 18 Park Crescent, W., the wife of Dr. Edward G. Reynolds—a daughter.

SMITH.—On August 22nd, at Low Bank, Queen's Drive, Mosley Hall, near Stockport, the wife of Mr. Smith.—a daughter.

STAM.—On August 15th, at 63 High Road, Streatham, S.W., to Dr. and Mrs. Louis Stam—a daughter.

WILSON.—On August 16th, at 96, Jesmond Road, Newcastle-on-Tyne, the wife of Frank Wilson, M.B., of a daughter.

HUMBLE DISPENSARY.

DALE STREET, STRETFORD ROAD, MANCHESTER.

WANTED.—A Barber, (suitable to having) a qualified Barber, Salary £120 for a full qualified. Salary £180 per annum. Annual increase £10 to £120, with apartments and gas and coal. Applications, with testimonials, at once to Honorary Medical Secretary.

Deaths.

CLARK.—On August 7th, at Brigstock, from double pneumonia consequent upon a severe attack of smallpox, Harry Edward Clarke, M.R.C.S., L.R.C.P., of 34 The Avenue, Bedfort Park, aged 57.

HUMBLE DISPENSARY.
The Medical Press and Circular

“SALUS POPULI SUPREMA LEX”

Notes and Comments.

One of the chief facts one must look forward to in the war that is now raging on the Continent is an enormous number of wounded. On no previous occasion in history has fighting been conducted on so vast a scale, and with the use of projectiles of similar range and power. A great many of the dead with great loss day by day are able to make a quick recovery—that is to say provided the requisite surgical treatment and nursing are available. The provision of an adequate medical service, however, difficult as it is in wars of ordinary magnitude, is multiplied tenfold in a struggle of the Titanic nature that has been forced on the world by the insane ambition of the German Emperor. So far as the British “casualties” are concerned, there can be little doubt that the resources of the Royal Army Medical Corps must be taxed to the utmost.

The first great conflict of our own troops, acting with the French, took place near Mons. Here our small force was opposed to the Germans in vastly superior numbers. By the sheer weight of their adversaries our soldiers were pushed back with great loss day by day in an action that lasted during the 23rd, 24th, 25th and 26th August. Lord Kitchener stated officially on Monday that Sir John French estimated the British casualties at between 5,000 and 6,000. As the fighting was continuous and the whole of the four days was practically spent in slowly retreating before a numerically superior force, it is clear that many of our wounded soldiers must have been left on the field of battle. The German losses, so it seems, clearly were far greater than our own, and as their time must have been fully occupied in pressing their attack and in looking after their own wounded, it is painful to think of the exposure and starvation to which the disabled British troops were of necessity exposed. Moreover, under the stress of a retreat the bearer and hospital arrangements share the general danger and confusion.

The Strain on the Army Medical Service. The plain truth appears to be that the care of the sick and wounded in this terrible war has thrown an enormous strain upon our medical men and the nurses. The ordinary needs of the population must be attended to, and all who can be spared are wanted at the front or the base hospitals, where, indeed, they cannot possibly supply more than a fraction of the skilled attention that is freely accorded alike to friend and foe, to combatant as well as to non-combatant. Those of our own wounded who can bear the journey are being brought over to England, where ample private and public hospital accommodation has already been provided. A great many medical men, both consultants and private practitioners, have thrown up their work and gone to the front, where they have been joined by what may be called the floating medical population, the men who do locum tenens work, the younger men who have not yet settled down to practice. This source of depletion in routine work has to be made up somehow, and it is to be feared that for a long time to come there will be a considerable shortage in the medical staffs of Poor Law and voluntary hospitals and asylums, not to mention other branches of public medical service. Some of the qualifying bodies have so far relaxed their regulations as to grant facilities for obtaining a diploma to senior students. The war has hardly begun in earnest so far as the United Kingdom is concerned, and it may pretty safely be predicted that sooner or later the demand for qualified medical men will be far greater.

The Extent of the War. Much the same thing will happen with the nurses. Already there is a shortage of nurses for private and public work at home. The Red Cross and St. John Ambulance Association are perforce utilising the services of women who are only partially trained. It must not be forgotten that the war more or less involves the greater part of Europe, and medical men and nurses are wanted, not only to tend our own troops, but also to carry on the work of mercy in the Servo-Austrian, the Russo-Austrian and Russo-Germanic lines, as well as the stupendous field of operations involved in the German invasion of Belgium and France. In a war of this scale and ferocity it may safely be assumed that the medical army will in many instances suffer more or less severe loss in spite of their non-combatant standing. The Germans have introduced into modern warfare the methods of their early barbarian ancestors. In not a few instances they appear to have deliberately violated the Red Cross badge, which is rightly regarded as sacred by civilised peoples. Apart from conduct of this kind there are many accidents that threaten army hospital staffs, especially in these days of rapid retreats and advances, and of battles carried on largely with long-range weapons.

Since our war with the Boers, Testing the great advances have been made in the organisation of the Army Medical Service, as in other branches of military administration. In that war
a great loss of life occurred amongst British troops from enteric fever and other preventable causes. The medical experiences of the present war will be followed with great interest, as a test of the efficiency obtained by our Army medical authorities. The small size of the British Armies has required a medical branch of correspondingly diminutive proportions. Now, with the sudden vast expansion of our combatant army a large addition is needed for its medical service, in order to bring it up to anything like a reasonable war footing. Whatever is to be attempted will have to be put in hand at once. It is probably far easier to enrol and train a second army within the allotted time of six months than to organise an adequate medical service in its behalf. In the period mentioned a man may acquire a good working acquaintance with drill, rifle-shooting, sword exercise, artillery and other warlike arts, but it takes four or five years to teach a man the fundamentals of medicine and surgery. Even then the young qualified medical man has to subject his theoretical knowledge to the test of practice before he gains the firm ground of experience. However, whatever the future may have in store as regards the medical men of the United Kingdom and this great war, the country will not lose in vain the members of the medical profession, young or old, obscure or distinguished, for that measure of duty, nobly and courageously discharged, which has been displayed in so marked a manner by all classes of our countrymen in the present crisis.

The report that cholera has already made its appearance among the British troops is only what is to be expected, even among the most favourable conditions of modern warfare. It is next to impossible to get men half dying of thirst to reject the muddy supply of water teeming with pathogenic bacteria within reach, and wait for the arrival of the field-carts containing aqua pura. The still small voice of science is silenced by the clamourings of human nature in its frailty and distress. So rapid is the multiplication of cholera vibrios, typhoid bacilli and coliform organisms under these circumstances that the specific diseases to which they give rise claim ten times the number of victims of those slain in battle. Nor as far as typhoid fever is concerned the danger is considerably enhanced from the probable presence in camps of "carrier" cases, and this source of risk is always an unsuspected one. During the past few days powerful pleas for the adoption of the practice of compulsory anti-typhoid inoculation have been advanced both in the profession and also in the lay press by Sir William Leishman and Sir William Ord. The method of anti-typhoid vaccination has the advantage of producing only a slight and seldom an incapacitating reaction and it is innocuous. It is earnestly to be hoped that strong pressure will be brought to bear upon the authorities with a view of rendering the practice compulsory. With regard to cholera we learn that a proposal is on foot to organise a special cholera corps to serve under the Russian Red Cross, consisting of ten medical men and twenty nurses.

The Danger of Unvaccinated Troops.

Another disease which is to be feared among troops is small-pox. LAughted by a feeling of a general fear felt by the absence of small-pox in epidemic form during the last few years, the populace in this country can hardly realise the gravity of massing large numbers of men together in camps, many of whom are insufficiently protected by vaccination or re-vaccination. In reply to a question in the House the other day, the Under Secretary for War stated that a circular had recently been issued informing General Officers Commanding that members of the Territorial Forces who had conscientious objections should not be vaccinated. It was felt, however, that the danger of an outbreak of small-pox among troops under the present conditions was far from being imaginary and that, consequently, every effort should be made to get men to be vaccinated while those who objected were being informed that unless they submitted to vaccination they would be of little service in the field. So far so good, but why leave anything to chance when so much depends upon the physical efficiency of each unit of the Forces? It should not be impossible to introduce a short Bill rendering vaccination compulsory for all fighting men, or, for that matter, for every citizen. The well being of a nation must predominate over the whims of a few unreasoning objectors. We cannot afford at this time in our history to take any unnecessary physical risks.
agencies that exist for the benefit of the vagrant. Through the help of the office established on Waterloo Pier a large number of homeless persons have not only been prevented from “sleeping out,” but have been actually brought into touch with those remedial agencies which place the applicants in a position to make a fresh start in life. The care of children has always constituted a special feature of the work of the Board, and it is satisfactory to note the progress made in connection with the reconstruction and enlargement of East Cliff House, Margate, which, when complete, will provide a sanatorium for children with 270 beds. The number of cases of ringworm of the scalp admitted to the Park Hospital during the year was 612, and, taking a date at random, it was found that out of 100 consecutive cases the number of days elapsing between the date of X-ray administration and that of the certificate of fitness for discharge was 30.2. It is satisfactory also to note that the treatment of trachoma by means of carbon dioxide snow has been carried out with success in a large number of cases. Turning to the report of the Statistical Committee we find that 33,994 cases of infectious disease were notified in the metropolis last year, as against 25,237 cases in 1912, the increase being due to a greater prevalence of scarlet fever, diptheria and enteric fever. Only one case of small-pox was admitted to the Board’s hospitals, and five cases of cerebrospinal meningitis. The difficulty which still surrounds the diagnosis of most of the exanthemata is once more illustrated by the fact that 9.0 per cent. of the total admissions into the fever hospitals were found not to be suffering from the diseases for which they were admitted upon notification. The number of admissions into the Board’s asylums was 943, as against 855 in the previous year. The ambulance service, both by land and river, has been kept very busy during the year, no fewer than 71,034 removals having been effected. The usual bacteriological laboratory examinations have been undertaken during 1913, and much useful work in connection with the preparation of antitoxin, tuberculin dilutions, etc., has been carried out. In the medical supplement to the report, after the usual comprehensive statistical tables, appear some interesting papers by various assistant medical officers of the Board, among which may be noted one on “Intramuscular Injections of Antitoxin in the Treatment of Diphtheria,” by Drs. J. D. Rolleston and C. R. Macleod; and one on “The Use of Physical Exercises in the Sanatorium Treatment of Pulmonary Tuberculosis,” by Dr. T. Nicol. Altogether the volume is a valuable record of the activity of a great public body, and it may be hoped that when the next issue appears it will bear the imprint of a newer and more comprehensive title than that of the Metropolitan Asylums Board.

Dr. Murdock Macdonald, M.D. Glasg., D.P.H., lately Assistant Medical Officer of Health and School Medical Officer for Huddersfield, has been appointed Tuberculosis Officer by the Deptford Borough Council.

CURRENT TOPICS.

**War and Humanity.**

The “naked fist” has fallen, remorselessly, murderously, upon poor defenceless civilians, men, women and children; upon wounded men lying helpless on the battlefield, claiming as a right the succour and the protection of humanity’s laws, and upon any inhuman and impious person, whose life has been brutally destroyed by the German troops. This is a dangerous system upon which to practise war in these days of civilisation. In the middle ages such wanton cruelty might have been excusable; excusable upon the ground that civilisation had not then sufficiently advanced to exert its refining influence upon the protection of human life and property. To revert, however, in this the twentieth century to practices which, in their murderous effects, could scarcely have been exceeded even in the days of savage warfare, has brought upon the vaunted Kaiser and his troops the execration of the civilised world. A nation whose military despotism has been based upon such foundation is common to every other. The world is not large enough to contain such braggarts, who, ruthlessly, deliberately, wantonly defy all dictates of humanity, and defile the name of humanity by their acts. There is “cricket” in warfare no less than in other things in life; warfare between civilised nations in these days does not imply, nor demand, nor does it create, a lust for blood, which no human instinct can control, even if we admit, as the Kaiser claims, that war cannot be successfully prosecuted “in velvet gloves.” There remains, therefore, the fact that no warfare can justify deluging the hands in the blood of defenceless women and innocent children, of which the German troops have been guilty, as eye-witnesses have testified. The advance of civilisation, if it has taught anything, has impressed upon humanity the sacredness of human life and its value: to the furtherance of that great principle the discoveries of science have been wholly directed. As medical men, we are in the position to judge, for example, how much the advance of medical science has diminished the horrors of war. The war has been a tremendous lesson to mankind, and of the advantages, and yet they deny to the poor victims of their savage cruelty the ordinary instincts of humanity, which the advance of civilisation has raised to so high a level of refinement. Thus has the Kaiser begun his megalomaniac war, not against the nations with whom he is fighting, but against humanity itself. Of course, we must assume that a War Lord, having adopted this plan of campaign, is conscious of what he is doing. At the same time he may have forgotten that history has shown that under these circumstances humanity is quite capable of taking care of itself, and of emphasising its power, not by reprisals, but by subjected to confound punishment the instigator of the violation of its principles.

**Circulars.**

There are certain small advantages that we owe to the present state of war. One of these is postal bombs and cartridges. We are used to circulars, universal and innumerable. There is no land within the Postal Union that does not constantly overwhelm us with soi-disant “literature.” The printed foreign pamphlet sometimes amuses us by the rich individuality of its alleged English. The most noteworthy thing about it is the endless variety of its postage stamps. Our English firms send us...
useful if monotonous packets of adorned blotting-paper. We use them and are thankful. The Continent relies on the printed word. Its reliance is often ill-founded. We are in no mood to appreciate ill-printed information in long-drawn hazy English. America is always trying to devise something new, and often succeeds in doing so. In this way comparatively expensive things that we hesitate to throw away for fear lest we should like to promote them to a position of positive utility in the vague future. Anyway, whatever goods the gods have provided us are gone. We shall have to buy blotting-paper and provide our own note-books. It is a hard fate to wake but exiguous spills, and when the maps are cut out, hardly that. It is one of the penalties of greatness. It is only now when the postman passes us that we see what we are missing. We used not to notice the advertising for the circulators. Now our supply is short and our memories are growing long. We remember. The gifts that we bestow in the days of their abundance are noteworthy because of their absence. Our interest in German synthetics is acute because we never hear from them and cannot get them if we want to. It is fate. It is always so. We are overwhelmed with what we do not want, and when we cannot get it, then, and not till then, we acutely realise our need.

The Husbanding of Energy.

In these days of high pressure and nervous tension it is astonishing that physical bankruptcy is not of more frequent occurrence. The human body can stand an immense amount of knocking about; in fact, the harder the blows the better. One thing our poor corpus vitreum cannot endure for long, even that is the continual ebbing away of vital energy, either from the expenditure of misdirected effort or as a result of perpetual fretting and worry over unimportant trifles. The hardest rock can be worn away in time from the constant impact upon its surface of tiny drops of water. Never was there such need for nothing all our resources and energies are at the present moment. As Sir William Bennett remarked last week at the opening of the Military Service Exhibition at the Institute of Hygiene, the great stress of the war will not come for some months yet, and then will be the time that the strain upon energy and resources will be greatest. Those workers who, under the stimulus of emotional excitement, are throwing tremendous energy into the work of preparation or of defence may be reminded that over-production always means waste and consequent loss of the power for doing good. A little judicious restraint and economy now will tell in the long run and will tend towards greater efficiency in the conduct of the war. "Self-control is the first secret of success" for individuals as well as for nations.

The Medical Profession and the War.

The response of the medical profession to the demands of the War Office for medical aid has been naturally gratifying. Young qualified surgeons of the necessary stamina are generally eager to engage themselves for war service. In doing so they not only supply one of the nation's needs at such a crisis, but they also benefit themselves by the opportunities afforded of gaining much valuable experience. The officers of the Royal Army Medical Corps, of course, are unable to provide the medical personnel required for war purposes. The medical establishment of the army is only sufficient for the needs of the Army on a peace footing. The ranks, therefore, of the Army Medical Corps have to be augmented by drawing upon the civil medical population when war supervenes. When the medical history of this war comes to be written it will probably be memorable for the high percentage of casualties in comparison with the losses from disease. The theatre of the war, as well as the arena of the lighting, are both in favour of the maintenance of the general health of the troops on either side. Again, the question of the commissariat department, at all events so far as the English troops are concerned, has been dealt with in a most perfect manner, judging from the reports which have reached us from men at the front. Again the need for medical and surgical consultants, it may be noted, has apparently not been so great in this war as it was in the Boer campaign, where the casualties occurred at so great a distance from expert assistance. Consequently there have been no lists of well-known physicians and surgeons appointed by the War Office for special duties at the seat of war, and yet we may be certain that if any such demand should be made by the War Office it would be readily and freely met, whatever personal sacrifice may be involved, in responding to the nation's requirements.

The Great Paradox.

We in these countries are watching, with a surprise gradually becoming dimmed by use, the hitherto unparalleled spectacle of a nation unanimously supporting the powers that it has raised up. Columns are written round the phenomenon and the utter marvellousness of the Anglo-Saxon is being fully dilated upon. No one seems to have pointed out that the nation is merely treating its experts as it has always treated its doctors. Medical men are not engaged for years on end by their professional instincts before their personal gains. That a reputedly sane people should give any body of men a pecuniary interest in cutting off its leg has been frequently pointed out as an instance of human imbecility. Mr. Shaw even manufactured one of his glittering insincerities to make so serious a subject as the average public trust in the people. We know the scrupulousness of the average doctor. He has got so schooled to do the best for his patient that it is a thing of the greatest rarity to find the trust abused. Of course, at first sight it seems absurd to make the executioner judge and then to pay him by the pound. Such a thing is outside the average common intelligence in theory. In practice the cutest business man follows the seemingly absurd principle with the utmost faith. And he is not disappointed. One may say that no other course is open to him, but we cannot believe that if the world thought its confidence chronically abused it would not have found a way out. The fact is that the average man rightly trusts his doctor. The Chinese way of paying the physician during health, and omitting all emoluments during illness seems logical, but we all know it would be no improvement. As a profession we are always cutting our financial throats, and we will keep on doing so. It is one of the queer kinks of human nature that, because we are trusted we justify the trust. Noblesse oblige is not yet out of date.

The Voice of the Doctor.

As America is about the only alleged civilised nation that has so far kept itself out of Armageddon, we may turn with confidence to her for the truthful things that used to interest us. She is actually discussing the voice of the doctor. We all
know the beefy tenor with the heaven-sent voice which he proverbially protects with a low collar and bottled stout. It seems that we must follow his star example if we wish to succeed in our calling. Commonsense and gentlemanly behaviour, we are told, are not rare in doctors, but a cultivated voice and a pleasing behaviour are said to be rather uncommon. The work often justifies the man, but unfortunately the man sometimes knows it. We all know the man who informs his patients that the cure will happen in the space of so many weeks if they do not follow his advice to the letter. That the statement is probably true, given an accurate prognosis, is beside the question. Listen to our urban American: "I cannot smoke; it would destroy my power of speech. I cannot use alcohol because it is so injurious to the tone quality and manner of expression that the harp J depend on to bring out the melodies of thought, counsel, and advice would be marred and broken." Now, to our shame be it said, a physician is accused of having used these words at a public banquet. Music is true it is the soft charm of heaven, but the man who is so self-conscious of his charms is clearly unfit for outside interests. He is of the sort of man that relies on his presence to make his patient feel better, though he does nothing for him. There is no doubt a grain of truth in this mass of objectionableness. Knowledge and power are no excuse for tyranny. The voice and manner may show confidence and the patient's interest in therapeutic properties of toxins. But more. Our most pernicious quacks are notorious for their charm of manner and consciously well-bred behaviour. They are as a sounding brass or a tinkling cymbal. To know is power. Dress it as you like. Appearance will never replace actuality.

False Charity.

We remarked last week on the large number of people who are at present demanding instruction in first aid and kindred subjects, and who may, if properly organised, fulfil an important function in the near future. It is with some reluctance we refer to another side of this popular movement. Much of it depends, and depends improperly and unnecessarily on the exploitation of the medical profession. In the present crisis medical men have not been lacking in performing the extensive duties called for by the nation's need. Many have relinquished their livelihood and the care of their families to take their places in tending the sick and wounded of our own forces and those of our allies. Others, who stay at home, are willingly taking the places of their brethren who have been called away, and performing their home duties without reward. In addition, medical men are offering their free services in attendance on the wives and children of soldiers at the front. Others are giving their services in the organisation and teaching of first aid and ambulance classes. It is on this last point we have a word to say. We believe that these classes are fulfilling a useful function. We believe, too, that it should be so arranged that every intelligent, able-bodied man or woman should, if he feels so called, have admission to a first-aid class. Where, therefore, classes are formed for working people, it may be necessary that the lecturer, who in most cases a medical man, should give his services gratuitously. In other cases the classes composed of well-to-do persons, we hold that the lecturer should invariably demand a remunerative fee. Unfortunately, this is not always done. We know of many centres where courses of lectures are being given by leading men in the profession without remuneration. These men are wasting their energies and resources needlessly at a time when these are especially needed by the country. They are forcing their charity on people who are not in need of it, and thereby debarring themselves from giving it where needed. By all means let any lecturer who chooses hand over his fees as a subscription to an ambulance association or a relief fund. We have no wish to limit the charity of our brethren. Charity wrongly directed is worse than a blunder; it is a crime. Giving free lectures on professional subjects to ladies who drive up in their motor-cars may be a good advertisement; it is not a public service.

The Mortality Rates and the Seasons.

The summer, now drawing to its close, has been exceptional for its healthiness. The years as they pass show how science has triumphed over the forces of mortality in lessening the toll from preventable disease. Formerly "a crisis in July," by which the disease was popularly known, used to claim a voluminous number of infants, whose deaths were mainly due to ignorance and carelessness during the heat of the summer months. With the progress of science, however, and the dissemination of the knowledge of hygienic principles, this toll of summer mortality has noticeably decreased within recent years, and the advent of an estival temperature has almost ceased to be a menace to infant life. The most fatal season of the year is now the period of the cold winter months, during which catarrhal attacks befall the aged, against which their enfeebled vitality is unable to contend.

H.M. THE KING, as Patron, has been graciously pleased to approve of the appointment of Sir William Bennett, Mr. Herbert Paterson, Mr. James Sherren, Mr. Lockhart Mummery, Mr. Crisp, Dr. William Hale White, and Dr. Charles Morris, C.V.O., as Honorary Members of the staff of King Edward VII. Hospital for Officers, 9 Grosvenor Gardens, S.W., during the period of the war.

H.M. THE KING, has been graciously pleased to sanction the following promotions in, and appointments to, the Order of the Hospital of St. John of Jerusalem in England (August 26th)—As Knights of Grace: Surg.-Gen. Sir A. W. May, M.R.C.S.; Col. J. E. Squire, C.B., M.D., F.R.C.P. (from Honorary Associate), and J. A. Sutherland, M.B.Edin. (from Honorary Associate).

Dr. Montagu Travers Morgan, M.B.Liv., D.P.H., has been appointed Assistant Medical Officer of Health for Herefordshire.

Dr. C. H. G. Ramsbottom, M.D., M.R.C.P., D.P.H., has been appointed Clinical Tuberculosis Officer in the Hampshire County Health Department.

Dr. Thomas Lewis, Assistant Physician to University College Hospital, and Editor of Heart, has been selected to deliver the Hester Lectures in October next at the Johns Hopkins Hospital Medical School, Baltimore.

The following consultants have been appointed by the Medical Department, Royal Navy, and in most instances have been detailed for special duties:—Sir Watson Cheyne, Sir William Macween, Sir Alfred Fripp, M.R. Turner, Dr. H. D. Rolleston, Mr. G. L. Cheal, Mr. Raymond Johnson.
CLINICAL LECTURE ON "FRACTURES."
By Sir Arbuthnot Lane, Bart., M.S., F.R.C.S.
Senior Surgeon to Guy's Hospital and Emeritus Surgeon to the Hospital for Sick Children.
[Specially Reported for this Journal.]

My experience of the operative treatment of simple fractures leads me to think that probably for the time being its indiscriminate use has done much more harm than good. The operative treatment has on the whole produced, I think, vastly worse results than if the patient had escaped that treatment, or even evaded the surgeon altogether. When you realise that in a series of cases published by Dr. H. B. Thomas in a communication read before the Chicago Surgical Society, March 6th, 1914, entitled "Bone Transplant," in about 48 per cent. there was suppuration necessitating the removal of a plate, the result must be regarded as simply disastrous. One feels inclined to employ an even stronger adjective to express one's views on the subject.

An American surgeon who came over here asked me how many of my plates I removed, I replied, "I don't remove any other than in the most exceptional circumstances." In support of this I referred him to the statistics of the Hospital for Sick Children, Great Ormond Street, where any infection of a fracture was unknown, although from the youth of the patients the operations are much more difficult than in adults. He inquired how he could find out how many were removed by surgeons generally. I advised him to go round and see the surgical registrars of the different London hospitals and obtain statistics from them. He did so, and he assured me that the statistics given to him showed that in between 35 per cent. and 7 per cent. of the cases operated upon for simple fractures the plates had to be removed. How far this statement is correct I am unable to say. It is approximately correct, those cases were examples of a defective or imperfect technique, or in plain English of incompetence to deal efficiently with fractures by this method, the failure being entirely due to want of care on the part of the surgeon. It is perhaps fortunate that the public are not aware of this fact. Some surgeons think that all they have got to do is to buy a certain number of instruments and to set to work. A proportion of surgeons would appear to have but an imperfect idea of the mechanics of the skeleton; otherwise you would never see bone-setters flourish as they do.

The bone-setter flourishes because the surgeon is deficient in a certain knowledge. Many surgeons do not realise that if you put a lot of foreign material, such as steel plates and screws, into a fracture or into any part of the body, you have got to exercise vastly more care than if you are doing an ordinary operation, only leaving in the wound a few little bits of silk or gut. That is the cause of infinite trouble. In the first place, the surgeon, sometimes knowing little about mechanics, has not a clear idea how to deal with a fracture when he sees it, and when he does operate he is likely to infect the wound, with disastrous results to the patient.

So far as the principles on which the operative treatment of simple fractures are concerned, I think there are three big flaws to which one can formulate in regard to influencing the growth of the body. Pressure produces certain changes, strain produces certain changes, and there is a third law, more extraordinary still, that if a new mechanism is useful to the individual or an old mechanism can be altered with advantage, that change may take place. Those three laws are at the basis of the growth of the body and are the foundation of evolution. That (pointing to a lantern view on the screen) is a perfectly normal skeleton of a man who carried barrels on his shoulder; he was a brewer's drayman. The peculiar pressure which he in consequence underwent for a long period of time produced certain changes which you see there. The general principle that nature goes on in attempting to meet a peculiar relationship of the individual to his surroundings is that of economy. If she can help you to do your work with the least expenditure of energy she does it, and you see how she has succeeded that he can carry his load easily by converting his normally flexible skeleton into a rigid shell so that he can do his work by an expenditure of the smallest amount of energy. The result is so marked and efficient that an old coal-heaver can handle a couple of hundred-weight of coal and do it all day long. You try to do it for five minutes and see the result. One curious thing about nature is this, that everything it does to develop this economy of expenditure of energy to help the individual in his particular labour tends to shorten the life of the individual. Take the coal-heaver, for instance. His spine, ribs and chest are all locked. That is all right for the man so far as coal-heaving is concerned, but let him have an attack of bronchiitis or pneumonia when he has to depend solely on the expansive action of the abdominal muscles to expel mucus from his tubes. Everything nature does to try and help us is only useful for a time; in the end it tends to act prejudicially to the interests of the individual.

Take the case of this coal-trimmer (a) who stands at the bottom of a hole and throws coal round to various points. In doing that he undergoes certain characteristic and remarkable changes. The man who carries anything on his head gets other changes. We all represent a definite mechanical relationship to our surroundings. Alter your mechanical relationship to your surroundings and you alter the machine. Go on repeating that for many generations and you transmit your tendencies to your offspring; although

(a) A remarkable example of the manner in which pressure changes in the skeleton may reveal the life-history of the individual.—Jour. Anat. and Phys., 1906, 383-406.
in the individual itself the actuality may not arise. (a) All these hard-working people die early simply because they are mechanically depreciated by their occupations.

As pressure produces change, so strain produces ossification in the line of traction. Anybody who has devoted much time to the study of the several occupation changes could recognise, for instance, the scapula of a shoemaker. (b)

I think I can best occupy the short time at my disposal by showing you radiograms of fractures taken before and after operation, as I imagine that by this means I can demonstrate the mode of treatment to the best advantage.

This radiogram shows a vertical fracture through the scapula. The fragments were situated in the neck near its outer limit. The outer fragment on the scapula is displaced downwards and forwards. The acromion has been torn away from the outer end of the clavicle and a considerable space intervenes between these bones.

Unless the scapula were restored to its original form the man who was a labourer would have been unable to follow his occupation because of the considerable displacement of the shoulder joint.

By cutting down on the fragments of the spine of the scapula which were grasped in strong forceps it was possible to bring them into accurate apposition, in which position they were firmly secured by a steel plate and four screws, which entered the free surface of the spine. Not only was the scapula restored perfectly to its normal form and function but the acromion was brought into its anatomical relationship to the clavicle. The man recovered with perfect function.

In this radiogram the fracture of the scapula was through the surgical neck, and here also the displacement of the outer fragment was considerable.

The fracture was exposed through the axilla. The fragments were placed in accurate apposition and were retained by a plate and four screws secured to the axillary or outer margin of the scapula. The result of operative interference was perfect functionally and anatomically.

This radiogram shows a fracture of the clavicle just outside its centre. There is very considerable downward and inward displacement of the outer fragment. By no means could these fragments be retained in anything approaching accurate apposition and it was of great importance to the man that the leverage action of the clavicle should remain intact and that the shoulder joint should be placed normally.

The fragments were exposed and accurate apposition having been effected they were secured by means of a plate and four screws, as is shown very distinctly in this radiogram.

Fractures of the clavicle are very readily dealt with by operation for the reason that the bone is always dense and strong and holds screws very securely, and also because it is very accessible, being immediately beneath the superficial structures.

The frequent presence of comminution adds to the advisability and advantage of operative interference.

The great objection to the operation is the presence of a scar. This only appeals to women. The scar can be made almost imperceptible.

The depression that results from an unsatisfactory return of the fragments in fracture of the clavicle is sometimes very great and usually very appreciable.

This radiogram shows a fracture through the epiphysial line of the upper extremity of the humerus. As is common in these fractures a portion of the shaft has remained attached to the epiphysis.

The fracture was exposed by an incision through the anterior limit of the deltoid made in this situation to avoid damage to the circumflex nerve. This fracture was restored to its normal position by means of an elevator. Once the fragments were in apposition, there was no tendency to displacement. The anatomical and functional results were perfect.

This radiogram shows a fracture through the upper part of the shaft of the humerus, commonly called its surgical neck. This variety of fracture always results from a direct injury. The upper portion of the shaft is displaced forwards, inwards and upwards. Perfect reduction by manipulation is usually impossible, while if the humerus is not restored to its normal form its function is impaired in a degree proportionate to the displacement of the fragments on one another.

This fracture was exposed by an incision similar to the last. The very marked overlapping was observed and the fragments being grasped with forceps were so manipulated as to bring the surfaces into accurate apposition. A stout steel plate was then secured to the fragments so that they were immobilised on one another. The result is shown in this radiogram.

This radiogram shows a spiral or torsion fracture of the shaft of the humerus through its centre. The displacement is very great, while the possibility of effecting any sort of apposition of fragments by manipulation of splints is very remote.

Contrast this radiogram with the last. It shows a transverse fracture of the shaft of the humerus just a little lower down. Here, as in other attempts had been made to so call "set" the fragments under an anaesthetic. In both these cases besides the mal-union of fragments which would necessarily result from the employment of the old and usual methods of treatment the risk of the musculo-spiral nerve being involved in the callus was by no means small.

In both instances as shown by these two radiograms the humerus has been restored to its normal function and form by operation and the fragments were secured by means of a steel plate and screws. All risk of damage to the musculo-spiral nerve was also eliminated.

In these as in all operations on fractures of the bones of the arm, great care must be taken to avoid damage to nerves or tendons. This risk is practically a negligible one in the case of the leg.

These radiograms illustrate the common fracture of the lower end of the humerus in young life. The exact position of the fracture varies; in some cases it runs through the junction of the shaft with the growing line while in others a variable amount of the shaft remains attached to the epiphysis. In some cases again only a portion of the lower epiphysis is broken off and displaced.
The objects of the surgeon are to effect accurate apposition of the fragments and to avoid the formation of a quantity of callus. The latter is a serious complication in these cases since the fracture traverses the olecranon or coronoid depressions. This is best avoided by keeping the fragments at rest for some time after they have been accurately replaced. Once the fragments are in apposition a retaining medium is very rarely called for. When a portion of the epiphysis is broken off and placed, it is sometimes necessary to employ a loop of silver wire to retain it where it has been replaced in position. It is always well to avoid any rigid control of a growing line in view of the law I formulated, viz.:

"The rates of bone formation in the several portions of a growing line vary inversely as the pressure."

The seat of fracture is best exposed by a posterior median incision through which the fragments can be replaced in accurate apposition.

The surgeon should not be satisfied with any result that is less than this unless equally to all operative treatment of fractures.

The radiograms that you now see represent fractures of the coronoid process, or of part or all of the head of the radius. These fractures call for very careful treatment. Should such a case unfortunately fall into the hands of a surgeon who is satisfied to treat all fractures by massage, etc., a bad result is certain to ensue. Nature resists any movement of such damaged joints, and endeavors to prevent its occurrence by the development of a bridge of bone which extends from the fragment of the coronoid process or radius upwards and backwards to the shaft of the radius. The term "ossifying myositis" has been applied by surgeons to this misdirected effort of Nature which stops pain at the cost of the destruction of the joint.

These radiograms show the condition in an early stage, and this the later stage when the articular surfaces are not only locked by a bridge of dense bone but are united to one another in an osseous junction. In such fractures it is wiser either to remove the broken fragment at once or to keep the joint at rest till the tendency to form callus has completely subsided. In other words wait till Nature has given up trying to help you.

The case which I have just shown you and which is illustrated by these two radiograms is typical and is constantly coming under observation. The patient was a girl, aged 13. She dislocated her forearm, backwards at the elbow-joint. The dislocation was reduced and the elbow at once massaged for twenty minutes. This massage was repeated on three occasions daily. On the third day an X-ray photograph was taken and it showed a fracture of the head of the radius with displacement of the fragments. The massage was still continued with the result that the range of movement in the elbow-joint became more and more limited. She then came under my observation. The second X-ray photograph which you have just seen was then taken. It shows that a bridge of bone has developed, extending upwards and backwards from the head of the radius through the muscle to the front of the shaft of the humerus. This is the earliest specimen of this condition which I have had an opportunity of observing. Numbers of late conditions as illustrated by this radiogram have come under my care. This shows a complete ankylosis of the joint with abundant bone occupying the angle of the joint.

In such cases a very extensive and difficult operation is required to obtain any sort of movable elbow-joint.

These two radiograms show fracture of the shaft of the radius in its upper third, each presenting considerable displacement of the fragments. This fracture requires very careful treatment because of the distribution of the musculo-spiral nerve in the supinator brevis where it surrounds the portion of the radius. It is impossible that the restoration of the shaft by the radius to its normal form and function would be dearly bought if paralysis of some of the small muscles supplied by the musculo-spiral nerve ensued. This can always be avoided if the operator takes care to avoid the nerves. An incision of a sufficient length to make exposure of the deep parts easy and effectual is particularly valuable in this fracture.

These radiograms illustrate the effect of operative treatment and the consequent showing perfect results. These four radiograms illustrate fractures of the olecranon in one case associated with fracture of the coronoid process. As seen in these other radiograms the fragments have been placed in accurate apposition, and have been secured by means of a plate and screws. In some cases two screws are sufficient, while in others four can be employed with advantage.

In the case in which fracture of the coronoid process was associated with that of the olecranon you notice that the frxation of the fragment of the olecranon resulted in the fragments of the coronoid process coming into accurate apposition. The patient who is an enthusiastic golfer tells me that his handicap has not been affected by the injury. When both radius and ulna are broken at about the same level, and there is marked displacement of fragments, it is always necessary to operate, if a good result is to be obtained.

These radiograms illustrate these fractures before operation. They show very considerable displacement of fragments. These other radiograms show the condition of the patient after operation, and you will notice that however severe the injury and however great the consequent displacement of fragments the bones have been restored perfectly and in every detail to their normal shape and function. Fracture of the lower portion of the shaft of the radius is almost always best treated by operation. When there is much displacement it is often very difficult indeed, if not impossible, to replace the fragments in accurate apposition. On the other hand the bone is subcutaneous here and is readily accessible so that the fragments may be easily replaced and secured by an operation. As in all operations for simple fracture the shorter the interval that is allowed to elapse between the receipt of the fracture and the operation for its restoration the better. This is true in an inverse proportion to the age of the individual. If there is much displacement or if the fragments and the displacement is not dealt with for a time, Nature makes great efforts to meet the situation by arranging for the laying down of a large amount of callus. The accurate replacement of fragments after an interval of time does not prevent the subsequent deposit of much of this callus though the necessity for its formation has ceased to exist. The resulting deposit of bone may be a great inconvenience
and may delay very materially the restoration of the bone to its normal form and function. This is a matter of great importance. These radiograms I am now showing you illustrate my meaning very clearly, showing the disadvantages of delayed operation. In the new-born babe who occasionally sustained a fracture during its exit every hour counts. Interference should be prompt. Such operations being very difficult at this age owing to the smallness of the bones, should not be undertaken except by those who are very familiar with their performance.

This radiogram showing fracture of the humerus at birth with extensive malmion and paralysis of the musculo-spiral nerve illustrates the disadvantage of delay. This second radiogram shows the humerus restored to its normal form. The musculo-spiral nerve was freed from the callus and the paralysis was cured. As some time had elapsed since the birth of the child the bones had softened and the operation was performed with great difficulty.

This radiogram shows a fracture of the femur of an infant. The bone is seen to be broken transversely an inch below the lesser trochanter. The displacement of fragments was very great. The operation was performed two days after birth, and you see the result in this radiogram which shows the femur restored perfectly to its normal form.

I regret that the time at our disposal prevents my showing you the conditions present in fractures of the leg and the mode in which they can be dealt with perfectly successfully by operation. The advantages of an operation over any other form of treatment are:—

1. The patient is at once relieved from pain, since all movement of the fragments is stopped.
2. He is freed from the tension and discomfort due to the extensive extravasation of the blood in the tissues, and from the inflammation that follows this.
3. The duration of his incapacity to work is as short as possible since union of the fragments is by first intention, no callus being required.
4. The bone being restored to its normal form the patient suffers in no way from the injury to his mechanics which he had sustained.
5. Since the fragments are united securely by one or more strong steel plates no controlling apparatus is required so that the patient can move the joints in association with the broken bone spontaneously from the operation and in consequence the prolonged convalescence owing to the stiffness which follows the use of splints, plaster cases, etc., is altogether avoided, and
6. The surgeon knows that by an operation he has secured the fragments firmly in accurate apposition and that he has no reason to dread the patient having his broken bone radiographed as soon as he is able to get about, and the necessity which may possibly arise to consult a solicitor to safeguard him against the results of his treatment as exposed to the patient by the photographs he obtains from the radiographers.

The only thing that is necessary is that the surgeon shall do his work efficiently.

—

THE RELATION OF THEORY AND PRACTICE IN THE OPERATIVE TREATMENT OF GENITAL PROLAPSE. (a)

BY HENRY JELLETT, M.D.Dub., F.R.C.P.I.,
Master of the Rotunda Hospital, Dublin.

Mr. President, Ladies and Gentlemen,—

My first duty is to thank you for the great honour which you have done to the Irish School of Medicine, and to that branch of it which is represented by the Rotunda Hospital, in inviting me to deliver this address. I can only say that I know the honour is appreciated by all connected with the Dublin School of Obstetrics and Gynaecology. I have next to thank you on my own account, and to express my pleasure at the great honour which you have done me personally. I cannot tell you how great a pleasure it is to me to have been able to come to this great country, even though the shortness of my visit enables me to see only the fringe of it. Already, I think, I shall go back with very pleasant recollections, and I can only hope that I shall leave some pleasant recollections behind.

The subject which I propose to take as the basis of my address is one which has interested me for a number of years, and which must have the greatest interest for every operating gynaecologist, namely, "The relation of theory and practice in the operative treatment of genital prolapse." It is a subject on which a volume might be written, and yet it has not always received the close attention of the operative gynaecology in which one is more inclined to be led by the fashion of the moment, and to adopt such fashion without due consideration of its ultimate results, and without attaching sufficient importance to its anatomical effects.

I trust I have not infringed the spirit of my directions, which were to deliver an address on obstetrics. Personally, I regard obstetrics and gynaecology as more or less conjoined, but my inclinations lie more in the direction of gynaecological practice. I have therefore assumed that I may translate the word obstetrics in its freest sense. Even if one wished to divorce gynaecology from obstetrics one can say of the subject I have chosen, that although prolapse may be cured by the gynaecologist, it is, alas, often produced by the obstetrician.

I think that in the past the frequent failure of the operative treatment of prolapse has been due to two causes. The first of these is an insufficient anatomical knowledge of the relations and supports of the uterus, and the second is a desire to find a panacea which will be suitable for every case. The second cause is directly the result of the first. One can quite understand, for instance, how the routine treatment of uterine prolapse by ventral fixation appeals to one who does not recognise the abnormal strain to which a uterus once prolapsed is subjected in the future, and similarly one can understand the attitude of those who habitually recommend hysterectomy on the one hand, or extensive vaginal plastic operations—such as colporrhaphy and perineorrhaphy—on the other.

(a) Being the Address on Obstetrics delivered at the Annual Meeting of the Canadian Medical Association, held at St. John, N.B., on July 8th, 1914.
It is such an obvious truism that if one removes the uterus, it can no longer become prolapsed, that it is little to the point of gynaecologists consider hysterectomy can cure prolapse. Again, it is so obvious that a prolapsed uterus ought to descend through the vagina, and cannot do so if the vagina is markedly narrowed that it is not strange that other gynaecologists think colporrhaphy and perineorrhaphy alone can cure prolapse. While as to ventral fixation, what is more plausible than to think that once the fundus of the uterus is fastened in an irremovable position to the abdominal wall, that is prolapse can occur again? Yet each of these reasonings is based on fallacy. The extirpated uterus has prolapsed once and for all, and is gone, but that does not prevent subsequent prolapse of the vagina, and genital prolapse does not consist of prolapse of the uterus alone. Descent of the uterus through the vagina can be prevented by a narrowing plastic operation, but that does not prevent the vagina as a whole from becoming inverted. The fundus of the uterus can be firmly attached to the abdominal wall, but that does not prevent the uterus elongating until its cervix and the vagina again appear outside the vulva. One might multiply other examples, but there is no need.

There are two cardinal points that one must remember in considering the treatment of prolapse. The first is that the exact lesions present differ to a very material extent in different cases. The second is that any treatment to be successful must follow such lines as enable us to alter and modify its details in order to suit the special lesions and complications of each individual case. Each and every one of these conditions will come under the head of genital prolapse, with the exception, perhaps, of the case of simple vaginal hypertrophy of the cervix. Here, although the cervix may appear at or outside the vulva, still the condition is not primarily prolapse, but one is justified in regarding all the other conditions as phases or varieties of prolapse, each of which will require different and special operative treatment. With these points in one’s mind, we come to the bedrock of all operative measures, namely, the anatomy of the pelvic, and when we understand it thoroughly we shall perhaps be in a suitable position to criticise older methods, or even to devise new ones.

I begin, therefore, by calling your attention to certain points of importance in the physiological support of the uterus and vagina, and I do it in the shortest manner possible. In one respect I ask you to give me your consideration. There is a considerable amount of divergence of opinion in regard to many of the points which I bring before you, and I ask you to remember that, as time will not permit of a discussion of these differences, I bring before you what I regard as facts, and what are my own deductions from them. It is no wonder that much divergence of opinion exists in regard to matters which at first sight appear to be so very capable of direct proof. There is no one so coy as the anatomist who comes to deal with pelvic anatomy, and the reason is not far to seek. I understand that the intelligent anatomist who is a good dissector can demonstrate to his own satisfaction, and to the satisfaction of his audience, practically any ligament or structure in the pelvis that he chooses for the moment to create. He can harden connective tissue with formalin and turn it into ligaments; he can exhibit muscles which in the living are incapable of demonstration; and he can resolve strong fibrous bands into succulent connective tissue. I hope my audience will not think from this that I want to undervalue the work which has been done in pelvic anatomy. It is far from me to desire to do any such thing, but I want to impress on you the great difficulty, if not impossibility, of demonstrating in the dissecting-room subject the instructions of anatomy. I must tell you that my hands are cut out for the dissecting-room, and I come to you with these words. We are not able to offer you the usual anatomists. The knowledge of anatomy is essential to the treatment of prolapse, but it is a knowledge which must be gained not alone in the dissecting room, but in examination of the living.

The two organs which are primarily concerned in genital prolapse are the vagina and the uterus, while secondarily, we find that prolapse of the bladder is very common, and that prolapse of the rectum seldom occurs without the involvement of the pelvic fascia.

The vagina, under normal conditions, is kept in place by three different structures. First, it is supported below by the converging bands of the levator ani muscle, with the coincident help of the investing fascia. Secondly, it is fixed to the pelvic wall by the vaginal suspensory ligament, which is a fold of the pelvic fascia, usually described as springing from the pelvic wall in the neighbourhood of the ischiatic spine, and passing inwards and slightly forward to the side of the vagina, and slightly posterior to a coronal median plane. I do not think, however, that this description is quite accurate, as I shall presently show. Thirdly, it is supported by its attachments to the cervix, and by the parts of the endo-pelvic fascia, which have an insertion both into the cervix and into the upper part of the vagina.

The urethra is supported (I refer now to direct support) by its vaginal attachment, by the utero-sacral ligaments and by the layers of the endo-pelvic fascia which pass into it laterally and anteriorly. Its indirect support I will discuss in a moment.

Each one of these structures which I have mentioned can be demonstrated clinically, and can be definitely proved by any close observer to be responsible for the utero-vaginal support. It is an easy matter to recognize the relation of the levator ani muscle to the lower part of the vagina, and to see how the approximation of its lateral ligaments support both the perineum and the lateral vaginal walls. The suspensory vaginal ligaments are also capable of easy demonstration, and so are the utero-sacral ligaments. To demonstrate them, one finger is passed into the rectum, and a bullet forceps is applied to the point of the vagina or uterus at which one wants to demonstrate the ligamentous attachment. Suppose, for instance, the forceps first catches the cervix. As one draws it down, one feels the utero-sacral ligaments because their tension is sufficient to resist further descent of the cervix. If one then applies a second forceps to the upper part of the vaginal wall at the junction of the lateral and posterior wall and pulls upon it, the finger in the rectum will feel distinctly the fascial band which runs to that particular point becoming tenece. If the forceps is then applied successively to a number of different points lower
We must now see how the injuries of labour affect both the direct and the indirect supports. The first and most obvious change is in the relation of the levator ani to the vagina. Deep tearing of the perineum destroys the slight attachments of the muscle to the central point of the perineum, and so allows its lateral bands to diverge outwards, while actual tearing of the muscle itself destroys the continuity of its inner edge. The result is that the lateral bands are widely separated and that there is nothing to prevent the anterior or the posterior vaginal wall from bulging directly down through the vaginal orifice. Once the support of the lower part of the vagina is lost, there is a tendency for the middle part also to descend, because the posterior and lateral walls, instead of resting on the levator muscle, are unsupported, and have their pull transmitted directly to the suspensory fascia which I have described. This fascia must be a very potent factor in supporting the vagina under normal conditions, but it is apparent that it does not possess great powers of resisting a continuous strain, and that when such strain comes upon it, it stretches, thereby allowing the middle portion of the vagina to descend. Clinically, however, I do not think that one often sees this progressive inversion. What happens is rather that first the lower part of the vagina protrudes, then the vaginal fornices lose their support and descend, and that finally, as a result of continued traction, the middle portion descends also.

The earlier descent of the upper part of the vagina is due to the alterations that occur in the supports of the uterus, alterations which usually result in the uterine prolapse, so to speak, over-taking the vaginal prolapse, and eventually preceding it. The first direct step in the production of uterine prolapse so far as the uterus is concerned is backward displacement. This may occur as a result of the traction of a prolapsing anterior vaginal wall on the cervix, a traction which tends to pull the anterior cervical wall lower in the vagina, so carrying the body of the uterus back, or it may be due to simple falling back of a large uterus as a result of general relaxation of its ligaments. Whichever it is, the effect is very much the same. The axes of the uterus and of the vagina tend to come into coincidence, and the resistance which the uterus offers to its own descent is altered from a surface corresponding in size to its anterior wall to a surface represented by a horizontal cross-section. In other words, practically all the support furnished to the body of the uterus by the pelvic floor is lost, and the weight of the uterus is thrown directly on to the utero-sacral ligaments and the different parts of the endo-pelvic fascia. The utero-sacral ligaments are strong bands, as can be easily proved clinically, but, like the vaginal suspensory ligaments, and indeed like all other fascial ligaments, once a direct pull comes on them, they yield. Their normal function is probably to keep the cervix in its proper relation to the posterior pelvic wall, and by so doing to keep the body of the uterus in front, and, once they receive the entire uterine weight, they fail, and stretch. Once they fail, the weight of the uterus is transmitted directly to its vaginal attachments, and to the endo-pelvic fascia, both of which are entirely unsuited to resist a direct strain. They too eventually yield, and so with the uterus the upper portion of the vagina comes...
down. It is probable, then, that the most common sequence of events is, first, the prolapse of the lower portion of the anterior vaginal wall, with or without an accompanying prolapse of the corresponding part of the posterior wall, then the prolapse of the uterus and the upper part of the vagina, and lastly, the prolapse of the middle portion of the lateral and posterior vaginal wall. This order may, however, be altered, and, as one sees in certain cases not associated with labour, the uterus may be the first part to descend, the inversion of the vagina being directly consequent. In each case the condition of complete prolapse with invasion of the vagina has occurred. I refer to hypertrophy of the supra-vaginal portion of the cervix. This hypertrophy is not confined to the portion of the cervix between the insertion of the utero-sacral ligaments and the vagina, but it is most commonly situated there, and it seems to indicate that there has been a conflict between the pull of a prolapsing vaginal vault below and the support afforded by the resisting utero-sacral ligaments above. It is consequently reasonable, I think, to suppose that when a hypertrophy of the cervix is present, the vault of the vagina has been the first part to prolapse, and the body of the uterus the last. In some cases, indeed, one actually sees this stage before uterine prolapse has occurred, that is to say, the utero-sacral ligaments are of their normal length, the body of the uterus is in a practically normal position, the vagina is inverted and the cervix is at the vulva, being enabled to come to this position as a result of its supra-vaginal attachment.

So far I have not referred to the alteration in the position of bladder that accompanies genital prolapse. It is the direct result of the pull of the anterior vaginal wall and of the yielding of the ligamentous attachment of the base of the bladder and of the urethra to the posterior surface of the pubis. It may be the first step to follow in injury to the pelvic floor, or on the other hand, it may be one of the later steps that result from the primary descent of the uterus. Once it has occurred it is only by hysterectomy that prolapse is certain, because it leads to straining and increased intra-abdominal pressure during micturition, and because it causes direct traction on the cervix of the uterus.

So much, then, for theoretical considerations. The more one studies prolapse, the more one sees how in its complete stage it is the result in most cases of an initial fault, which, by altering the normal strain to which the suspensory mechanism of the uterus is intended to be subjected, throws them out of sympathy with one another. This is the most essential point to grasp in planning a successful operation for prolapse, because just as the prolapse follows initially a single fault, so it will tend to recur after operation if a single weak point is left. Ventral fixation alone failed because the cervix was free to drop into the axis of the vagina, and so again to bring a direct pull on the utero-sacral ligaments. Vaginal plastic work, alone, failed because the descending uterus was capable of again dilating the vagina and forcing the muscles apart. Hysterectomy failed because it took no account of the fixation of the vaginal vault.

We have now to see conversely if, when once prolapse has resulted, it is possible not alone to bring back the different structures to their normal relation, but also to abolish all abnormal strains which may be thrown upon them. I think that one may consider rational prolapse operations to be divided into three periods:—First, the restoration of the normal direct support of the uterus and vagina so far as possible; secondly, the placing of the uterus in such a position that it offers the maximum resistance to descent; thirdly, the removal of complications and associated conditions, the result of prolapse. I will deal with these three parts separately.

**The Restoration of the Normal Direct Support of the Uterus and Vagina**

We have already seen that these supports are four in number:—First, the utero-sacral ligaments; secondly, the endo-pelvic fascia; thirdly, the suspensory ligaments of the vagina; and fourthly, the levator ani muscle. The shortening of the utero-sacral ligaments with a view to restoring their normal action on the cervix is advisable in all cases in which they are stretched. It is essential when one is dealing with a small uterus, because such a uterus cannot be made to offer sufficient resistance to its own descent unless its direct supports are also re-constituted. Wertheim was, I think, the first to recognise the importance of shortening these ligaments, and his operation is carried out by the vaginal route, but through the peritoneal cavity. I have also described a method of shortening the ligaments through the vagina at their point of attachment to the uterus, and this is the method which I usually adopt, as I consider it to be more easily worked in with the other stages of a prolapse operation than is Wertheim's method. It is unnecessary to enter into its details here, though I hope, if time permits, to say a word about them later. It is, however, necessary to say why utero-sacral shortening is so essential in the small uterus, and the reason, if one thinks of it, is obvious. In a moment I shall go on to say that I consider Wertheim's interposition operation to be one of the best methods of increasing the resistance of the uterus against prolapse. In this operation, the uterus is placed between the anterior vaginal wall and the bladder. If the uterus is of sufficient size, it is then directly supported by the levator ani muscle, as well as by the vaginal wall, and, furthermore, since it is too large to allow its body to remain in position while the cervix rotates round it and comes down again to the vulva, the result of the operation is usually excellent. If on the other hand, the uterus is very small, the cervix if free, can drop through the vagina, pull the remainder of the uterus after it. If, however, we fix the cervix by shortening the utero-sacral ligaments, it cannot rotate round the body and drop, while, at the same time, the strain on the shortened ligaments is slight, and they do not tend again to elongate.

The shortening of the band of endo-pelvic fascia, known as Mackenrodt's ligaments, has also been advised in cases of prolapse. Some of the advocates of this procedure support their view by saying that Mackenrodt's ligaments must give a great deal of support to the uterus, because their division during the course of Wertheim's hysterectomy allows the uterus to be pulled to a much
higher level. This argument, however, in my opinion, is based on an inaccuracy. It is not the division of Mackenrodt's ligaments that allows the uterus to be pulled to a higher level, but rather it is the division, first of the uro-sacral ligaments, and then of the vaginal suspensory ligaments, as I have already mentioned. At the same time, although I do not believe that Mackenrodt's ligaments have all the effect on the uterus which is sometimes attributed to them, I think that when they are shortened they are capable of adding to the general support of the cervix. Such shortening, to be effective, must be considerable, and if it is to be a safe procedure, it must be done with the greatest care, because, as we know, this part of the endo-pelvic fascia is pierced by the ureters, and if it is drawn out too far I think that it is quite possible that kinking of the ureters may result. A moderate degree of shortening is always brought about when supra-vaginal amputation of the cervix is performed, in consequence of the insertion of these ligaments into the upper part of the vagina as well as into the uterine cavity, and, personally, I am not inclined to try to shorten them to a greater extent in this way.

The support given by the vaginal suspensory ligaments is of the greatest importance, and if it was feasible to restore them to their original condition, such a step would be most desirable. At the present time, however, I am not aware that any operator has suggested any effective method of dealing with these ligaments, and for my own part, I can only say that I do not see that it is likely that such a method can be brought forward, owing to their position. The nearest approximation to them is the fixation of the vault of the vagina to the peritoneum covering the anterior surface of the sacrum, as was suggested by Stanmore Bishop some years ago. The only objection I can see to this procedure is that it necessitates an abdominal incision, and this adds on rather too much to an already prolonged operation. Personally, I have not performed Bishop's operation, and I do not think that it has received from anyone the attention which, on theoretical grounds at all events, it deserves. Further work on the fixation of the vagina is very necessary, and, if it is carried out, it is possible that an effective procedure for the restoration of the important fascial connection of the posterior vaginal wall may be devised. For the moment, however, we must consider that our efforts to restore the direct support of the vagina break down at this point, and that we are not capable of restoring effectively the vaginal suspensory ligaments.

The restoration of the levator ani muscle to its proper position according to its normal strength, a matter of ease and simplicity. It is an essential part of all perineorrhaphy operations, and is a step of the utmost importance in prolapse operations. I do not propose to enter into the method of suturing it on the present occasion, but will confine myself to saying that it is always possible and usually easy, except when the muscle has practically disappeared on one or both sides in consequence of atrophy or excessive retraction.

The Placing of the Uterus in Such a Position That it Will Offer the Maximum Resistance to its Own Descent.

We have seen that under normal conditions the uterus lies practically horizontally in the pelvis, and that its resistance to descent may be expressed as that of a surface corresponding in size to the anterior surface of the uterus. On the other hand, when the uterus comes into a position of retroversion, usually the first stage of prolapse, the resistance that is offered may be expressed as that of a surface the size of a horizontal cross-section of the uterus. Furthermore, when in a position of retroversion, the uterus descends into the pelvis as a wedge, point downwards, and so readily forces or dilates a way for itself through or between any opposing structures. Finally, when the uterus offers a maximum resistance to its own descent, not only does this increased resistance directly hinder descent, but it also lessens the strain which is thrown on the direct supports, and this is a most important matter. I do not think that it is possible by any means to reconstruct the direct supports in such a manner that they will resist the entire strain of the unsupported uterus, but if this strain can be brought back to its normal limit, then, in association with the reconstituted direct support, the tendency to prolapse will be overcome. The simplest method of bringing back the resistance of the uterus to the normal is by fastening the fundus in a position of anteverision. This can be done either by the shortening of the round ligaments or by the direct suture of the uterus to the abdominal peritoneum as is done in ventral suspension, and, as neither of these procedures in any way interferes with a subsequent pregnancy, one or other of them is indicated in the case of women still within the child-bearing period. It is, however, possible to increase the resistance of the uterus beyond the normal, but such a course inevitably affects detrimentally a future pregnancy, and may lead to the most serious results. Therefore, it is obviously only permissible in women who are past the child-bearing period, or in women in whose case there is no objection to producing an artificial sterility. The most important and the most reliable of such operations is undoubtedly Wertheim's interposition operation, and I have no hesitation in saying that it is the most valuable procedure which has been introduced of late years, for the cure of prolapse, because, not alone does it increase the resistance of the uterus to its own descent, but it also helps to fix the vagina in position, and to remove the prolapse of the bladder that both complicates and tends to perpetuate vaginal prolapse.

I have stated briefly of what the operation consists, namely, the bringing of the body of the uterus to lie between the bladder and the anterior vaginal wall. In this position, it is entirely extra-peritoneal, and so undergo proper development during pregnancy. The bladder is brought to lie wholly above it, and, provided the size of the uterus is sufficient, and that the cervix is fixed by the shortening of the uro-sacral ligaments, I consider the result cannot at present be surpassed. On the other hand, where the uterus is small, and the cervix is not fixed, recurrence of the prolapse is very liable to occur.

We now come to the third part of the rational prolapse operation, The Removal of Complications and of Conditions Associated With Prolapse.

There are a number of conditions which are either the direct result of uterine prolapse, or one
or more of its predisposing causes. In the cervix we may find hypertrophy—vaginal or supra-vaginal, so-called erosion, true ulceration, and laceration. In the body of the uterus we find endometritis and the different conditions which are usually grouped under the head "metritis," and which lead to uterine enlargement, and tumours such as myomata. In the pelvic and abdominal cavities we find adhesions and adhesions arising either in the uterine appendages or from other organs, and ascites, while, lower down, we find very frequently prolapse of the bladder, more rarely prolapse of the anterior rectal wall, and, most commonly of all, perineal laceration. It is obvious that these conditions must be removed if a successful result is to be obtained, and it is only necessary to say a few words about them. Erosion, laceration, and hypertrophy of the cervix are best treated by amputation of either vaginal or cervical myomata, according to the nature of the case. Endometritis is treated by curettage. Uterine tumours and abdominal pelvic tumours call for removal, while increase in the size of the uterus, apart from tumour formation, calls for reduction in its size by the amputation of a wedge-shaped portion from the body. This procedure is particularly necessary if Wertheim's interposition operation is to be performed, and, if it is omitted, trouble is likely to occur during the operation, owing to the impossibility of properly fixing a subjacent vaginal mucous membrane to cover the large uterine body, and also later, owing to the pressure which the large uterine causes at the lower part of the vagina. In such cases, the excision of a wedge-shaped portion of the body is essential, and does not add much to the length of the operation. Prolapse of the bladder is cured whenever the interposition operation is performed, and when the latter is contra-indicated, it can be cured by the performance of anterior colporrhaphy, which can sometimes be done by passing the displaced bladder back into its proper position before suturing the edges of the vaginal mucous membrane. The cure of a prolapsed rectal wall is directly associated with the cure of perineal laceration, and as this operation involves the suture of one of the direct supports of the vagina, namely, the levator ani muscle, I have already referred to it in its proper place.

Mr. President, Ladies and Gentlemen,—I have tried to place before you the theories on which I think the proper treatment of uterine prolapse must be based, and to indicate briefly the manner in which one transforms them into practice. To suggest that the result of operating along these lines is uniformly successful would be equivalent to saying that we had reached finality, and this is very far from being the case. All one can say is that we are beginning to adopt measures because of their probable permanent result, as opposed to measures which merely give a temporary benefit. There is, however, much room for improvement. So long as the posterior vaginal wall is left, as it is at present, with its supports in an imperfect condition, so long must operative procedure be defective. There are other points, too, in which improvement must come. The interposition operation is excellent in a suitable case, but it is incompatible with pregnancy. The restoration of the pelvic floor is in most cases effective, but it may be again destroyed during a subsequent labour. The very means which we adopt to reduce an enlarged uterus to a normal size may subsequently result in producing uterine atrophy, and so in removing the most effective part of the modern prolapse operation, namely, the placing of the uterus under such conditions that it resists, not alone its own descent, but the descent of the structures by which it is surrounded.

I have thanked you on my own behalf for the honour you have done me, and I could only wish that, for the reputation of the school which I represent, you had selected one who was more suited to put before you some of the problems of modern obstetrics and gynaecology, and their solution.

ACQUIRED AND HEREDITARY SYphilis.

By Prof. Paul Rostaine, M.D.,
Late Director of Claires at the Faculty of Medicine of Paris.

[Specially reported for this Journal.]

It is generally supposed that heredo-syphilis cannot contract syphilis de novo, and this view is not confined to the latty, indeed it is shared by certain practitioners. Instances of this are by no means rare. Here is one under my own observation. A gentleman whose son had just finished his college course informed the latter that he had had syphilis in years gone by, and recommended him to mention the fact to any medical man to whom he might have occasion to apply by reason of venereal disease in order to prevent their falling into error. This may be taken to mean that he was under the impression that the syphilis which he had contracted before the birth of his son protected the latter against infection. This idea must have been firmly anchored in his head for him to undergo the humiliation of communicating the fact to his son. Tarnowski relates a similar instance. The patient in question was suffering from manifest syphilis calling for a prolonged course of treatment, but this the patient absolutely refused, saying that he had not been in a prostitute for at least twenty years, and had on several occasions had exactly similar ulcers which had healed up without trouble. Anyhow, he added, he could not have contracted a fresh infection seeing that his father had had syphilis, and that his birth was subsequent to the paternal infection. He was firmly convinced of his invulnerability on the strength of what his father had told him, and later on, he said, he had had plenty of opportunities to satisfy himself of the impunity of connection with syphilitic women.

The persistence of this error is due to the fact that the question of syphilis being acquired by heredo-syphilis is never properly formulated. There are degrees in heredo-syphilis which are not taken into account. We talk en bloc of heredo-syphilis without allowing for the categories which nature has established according to the virulence of the lesions which these subjects present.

The question was for the first time postulated clearly and categorically by Professor Gaucher in 1903. In one of his clinical lectures he showed that it is only in certain conditions that inherited syphilis affords any protection against infection. In speaking of inherited syphilis we must be careful to specify the form in which it was manifested. There is considerable difference between a subject of inherited syphilis who is dystrophic, presenting dental lesions and one who displays
the secondary and tertiary accidents of inherited syphilis. It is therefore indispensable to subdivide these cases of inherited syphilis into several groups before we start discussing the degree of immunity conferred by parental syphilis towards subsequent direct infection.

In the following year Professor Gaucher elaborated a classification of cases of heredo-syphilis according to the different clinical types and the degree of virulence of the transmitted disease. In enumerating the manifestations of inherited syphilis in living infants born at term he pointed out that the disease may give rise to various manifestations throughout their entire existence, because hereditary syphilis does not merely mean congenital syphilis or infantile syphilis, but comprises all the accidents dependent on the transmitted disease from birth onwards.

We require to classify these multiple manifestations in order to study them as a whole. They have been placed in two groups: (1) the manifestations of what has been termed early hereditary syphilis; (2) late manifestations of hereditary syphilis. This classification is not quite accurate because, in the so-called early hereditary syphilis, we get lesions of very different standing. In cases of premature delivery, for instance, we may meet with certain focus which are born with dystrophies which are the delayed lesions of a distant, attenuated infection, while others come into the world with generalized lesions of secondary syphilis. To retain this classification we should have to specify that the symptoms of syphilis occurring immediately after birth or during the first few months of life are of different standing, that there may be hereditary, secondary or tertiary accidents, parasyphilis and dystrophies. Professor Gaucher classifies them as follows:—1st degree: Secondary heredo-syphilis, which resembles in respect of its manifestations the acquired secondary syphilis of the newborn. This is what Fournier calls "decapitated" syphilis, which, except for a different origin and the absence of a chancre, presents all the features of secondary acquired syphilis with which it may be assimilated. 2nd degree: Tertiary heredo-syphilis, an attenuated form of syphilis presenting tertiary lesions which are generally the delayed manifestations of a syphilis that is on the decline. 3rd degree: Quinary heredo-syphilis, represented by manifestations of what we may call dystrophic hereditary syphilis, in the shape of congenital malformations developed in utero under the influence of parental syphilis and caused by the disturbance of nutrition and development entailed by the infection.

These four main divisions enable us to approach the question of syphilis acquired by heredo-syphilitics under the various aspects in which it may present itself. They establish clearly enough that heredo-syphilitics do not all receive from their parents an infection identical in virulence, and to grasp the probability that the immunity conferred by reason of parental infection cannot be the same in all cases, in fact that there are "degrees of wickedness." I will now discuss each of these categories separately from the point of view of the protection afforded to the subjects in each.

Before discussing acquired syphilis in heredo-syphilitics properly so-called, we must enquire how the descendants of syphilitic parents who have never presented any signs of heredo-syphilis behave in respect of acquired infection. An infant born healthy, of syphilitic parents, is not, as a matter of fact, a heredo-syphilitic in the ordinary acceptance of the term since he has not inherited any pathological strain. He is not syphilitic and cannot therefore have inherited any degree of immunity to syphilitic infection.

Quinary heredo-syphilis manifests itself by dystrophies—the characteristic dental anomalies, skeletal dystrophies such as the OhlHappy forehead, the arched palate, the platybasium, dystrophies of other organs, e.g. marginate exfoliative glossitis and squint, the importance of which in the diagnosis of heredo-syphilis has been worked out by Professor Fournier.

Quaternary heredo-syphilis comprises the so-called para-syphilitic affections such as hydrocephalus, juvenile tabes and infantile general paralysis.

I have collected some fifty cases of acquired syphilis in quaternary and quinary heredo-syphilitics. This means that in these two groups the individuals behave exactly like normal subjects when exposed to the infection of syphilis. This is readily explained by the attenuation of the virus of the inherited syphilis either on account of the length of time that has elapsed since the parental infection or the effects of specific treatment. We may therefore conclude that quaternary and quinary heredo-syphilics are liable to contract syphilis in the same way and with the same case as the normal individuals.

The tertiary manifestations of the heredo-syphillic differ in no essential particular from similar manifestations in acquired syphilis. I was able to bring together in my thesis sixteen instances of this class, two of them under my own observation and the others published by syphilographers of renown, such as Hutchinson, Merkel, Wolf, Lang, Emery and Jullien.

These cases are rare but they are unquestionable, and I think it must be conceded that under certain circumstances, when the virulence is much attenuated, tertiary heredo-syphilitics are liable to contract syphilis.

To talk of acquired syphilis in the subjects of secondary heredo-syphilis is to raise a question involving doctrinal conceptions and problems of general pathology which I shall not attempt to solve. It opens up the whole question of the possibility of reinfection. "What one would like to see," says Professor Fournier, "would be an hereditary syphilitic presenting the accidents of secondary syphilis at birth who, in later life, contracted syphilis. Personally I know of no such instance."

I have only been able to find one instance in medical literature of syphilis acquired in a subject who presented the accidents of secondary heredo-syphilis, viz., a case reported by W. Taylor, and it would not be safe to dogmatise on the strength of this single observation in favour of the possibility of the reinfection of syphilis.

It follows that although syphilis in the form of tertiary heredo-syphilics does not always afford immunity against reinfection, inherited secondary syphilis, true "decapitated" syphilis, does confer that immunity, and that in cases in which syphilis was acquired by the subjects of secondary heredo-syphilics this would really amount to syphilitic reinfection.
CLINICAL RECORDS.

A CASE OF RUPTURED UTERUS FOLLOWED BY RECOVERY.

By THOMAS RARBY, M.D., R.C.H., D.P.H., Thurl.

On July 12th, at seven in the evening, I was called to see Mrs. C., a farmer's wife, and got a history that she had had six children previously, all born without difficulty or even the attendance of a professional nurse. She was at work as usual the previous day, when pains came upon her, but to try to bear down. A few hours later, the pains became more frequent, and remained about three hours and left as the pains ceased. She was again called at 8 in the morning, as the pains had returned. They persisted at intervals until two in the afternoon, when they ceased altogether, after which the patient got gradually weak, and I was sent for in the evening at seven o'clock.

The account given that at question, was the labour severe, nor was there any sudden internal pain or sensation of "something giving way," which is commonly described in cases of rupture of the uterus.

On examination I found the patient in a very collapsed condition. The face was pale and drawn; the pulse rate was 160 per minute, and appeared very unnecessarily alarming. The abdomen presented a curious appearance, as if the uterus were in two parts. No vaginal examination was done, but severe, hemorrhage, and the presenting head, which was far up, could be felt.

From all the conditions, I suspected rupture of the uterus, and sent for Dr. Jackman, of Thurl, in consultation. On his arrival the careful search for the entrance of the patient had become even more extreme, and, on vaginal examination, no presenting part could be felt, which suggested that the fetus had by this time escaped from the uterus. Dr. Jackman confirmed the diagnosis, and we decided to deliver, if possible, as an abdominal operation was out of the question. There was no haste, but we were ready for any eventuality. The abdomen was opened, and the uterus found to be in two parts, one lying quite beside the other, and appearing quite normal. The abdomen presented a curious appearance, as if the uterus were in two parts. On vaginal examination there was some, but not severe, hemorrhage, and the presenting head, which was far up, could be felt.

I reached the child's feet and brought them down, and delivery of the body and shoulders was accomplished without difficulty, but the head was quite difficult, and the birth was attended with much trouble. It was brought out with difficulty, and the head was squeezed, and the birth was attended with much trouble. It was brought out with difficulty, and the head was squeezed, and the birth was attended with much trouble. Next morning she was much better with a pulse of 110. She complained of great tenderness, and vomited slightly. I changed the gauze packing which was blood-stained. The abdominal tenderness was followed by swelling and hiccough, and there was plainly a certain amount of peritonitis.

The gauze was changed for four or five days, and then dispensed with altogether. Vomiting was very troublesome for some days and caused great pain which was located in the womb. The latter organ could be felt in a hard mass in the right iliac region. After two days the bowels moved naturally. Diarrrhea set in and was present at intervals for two weeks. The urine was dysuria, and had a disagreeable smell. It began to appear from the vagina and continued for a week, the abdominal swelling and tenderness gradually disappearing at the same time. It was clear that the inflammatory fluid was being drained from the peritoneum through the rent in the uterus.

At the end of three weeks all signs of abdominal trouble had disappeared and the woman had recovered, but, unfortunately, she had been confined in a lunatic asylum some years ago and mental symptoms again began to appear, which have not as yet quite passed away.

I think this case is quite worth bringing to the notice of the profession as many of us in country districts would have little hope that such a one would recover under non-operative treatment.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

Having operated upon an inguinal hernia in a child and an umbilical hernia in an adult, Mr. Corner said that there were three important clinical considerations about each of these sets of hernia. Hernia is a very common condition, and in consequence it behoved all men to understand the symptoms and wherefore about them.

Why did we operate on these hernias? Operation is recommended or done on all hernias, unless there is a contra-indication special to the patient. In other words, operation is the first line of treatment. Why? Chiefly for two reasons: the disabilities of the patient and the quality of the operation. Let us begin with the disabilities of the patient. Firstly, the condition is incurable without operation: apparent cure is hazardous, and a hour is dangerous, especially in those of the sure of security it gives. Secondly, a man is a incurable, distressing thing to wear, fraught with disadvantages to the rubbed and squeezed tissues, as well as to the patient. Moreover, it is a danger, being often worn on the hernia, does not come instead of under the hernia, in this way being responsible for inflammation, adhesions, irreducible and graver accidents in the contents of the hernia. Thirdly, and a business consideration, no service, civil or military, will accept a person with a hernia. He is rejected for any active life, civil or military, and is a "cracked pot." In fact, the disabilities of the hernia-patient can be made into a long list of thistles and thorn's, and as it might bring weedy recollections of the Sabbath's sermons, it is well to be satisfied with indicating that the presence of a hernia is a great nuisance, a great disadvantage, and a possible source of danger. Moreover, the disadvantages and dangers are greater in femoral hernia than in inguinal, and still greater in umbilical than in femoral, whilst internal hernia which need not easily declare themselves, and are ever so dangerous the external hernias which show their presence. Obturator and diafragmatic hernia may be classed with internal hernia.

Mr. Corner then pointed out that special reference must be made to the hernia of children, because in them operation was aided by the subsequent growth of the region, and it was possible to do more for children than for adults.

As to the qualities of the operation. These operations have changed much in the last ten years: they have risen from 342 (practically one a day) to
about 700 (two a day). This shows the great appreciation of the benefits of the operation by the working classes. The duration of the convalescence is short—a fortnight in bed. The danger of the operation is practically nil. The pain of the operation is much less, owing to the absence of inflammation, than it was ten years ago. The possibilities of cure are nearly as good as those observed by Sir John Galt, who met a sure ground of dispute, recently recurred took place in about 4 per cent., and ten years ago in about 3 per cent. These numbers appear too small, but they serve to indicate the progress, by bearing witness to the improvement in technique, the percentage of recurrence of hernia after radical cure has not fallen in the last ten years—it is the patient’s misfortune or fault, not the surgeon’s fault or failure; secondly, more or less fit people are seeking the benefits of operation for their hernia.

For a third consideration are the essential points in an operation for the radical cure of a hernia. In order of importance they are: Firstly, the complete removal of the sac; secondly, healing by first intention (i.e., of the deeper parts of the wound); thirdly, suture of the canal. This order of merit for consideration is designed for its application to inguinal, femoral, and obturator hernia. But an suture of the canal is of prime importance in the radical cure of umbilical and ventral hernia. Hence the surgeon’s work can be easily done well, and the result must be great. It is only necessary for the surgeon to work with. Simplicity of operation, so long as it is sufficient for success, is the best. Do not waste time in the exact suturing of inguinal canals.

The question of operation for all kinds of hernia has been considered briefly, and it is explained why operation is desirable in all cases, unless some condition of the patient indicates otherwise. Further, operation is more necessary for umbilical and ventral hernia than for femoral hernia. Operation is more needful for femoral than for inguinal hernia. In the last is seen more the operation of expediency than the operation of necessity, which figures first in umbilical and femoral hernia.

UNITED STATES OF AMERICA.

AN ACT TO CONTROL OPium TRADE IN U.S.A. AT HOME AND ABROAD.

(Concluded from our last issue.)

Dr. Hamilton Wright has sketched the principles to be contained in such an Act, and has embodied them in his report to the Secretary of State on behalf of the American Delegates to the International Commission which sat a Shanghai in 1909.

(1) That such an Act should demand the registration of every person who imports, produces, manufactures, compounds, distributes, or otherwise handles habit-forming drugs in interstate or foreign commerce.

(2) That importers, wholesale compounding pharmacists, and wholesale dealers should pay a small per annum tax, and that retail pharmacists and other retail dealers, including physicians who buy in interstate commerce and who carry large supplies of the drugs, should pay a tax of from $1 to $3 per annum; that everyone engaged in handling drugs should register and pay a tax.

(3) That, without attempting to derive a revenue beyond the amount necessary to administer the Act, all of the habit-forming drugs should have imposed upon them an internal revenue tax, and that such tax should be paid by affixing to packages or other receptacles containing the drugs, an engraving stamp, to be affixed and cancelled according to law.

(4) That all compounds or preparations manufactured from the original tax-paid drugs should be marked or branded in such a manner as to show the payment of the tax on the original drug.

GLASGOW.

UNORGANISED HOSPITAL AID FOR WOUNDED.

The Scottish Branch of the British Red Cross Society have issued a statement deprecating the well-meaning but unauthorised endeavours that are being made in some places to form local hospitals. This action on the part of voluntary aid detachments of the Society is calculated, they say, only to cause confusion and unnecessary trouble, without fulfilling any useful purpose. The control of the voluntary aid detachments is now in the hands of the Territorial Force, and the Territorial Force is mobilised, from the Red Cross Society to the military authorities. Ample provision for the care of the normal per centage of sick among those troops that are present and quartered in the country has already been made, and the only chance of large numbers of wounded being in any particular part of the country, unless transported there, is if there is actual fighting in that part of the country. The military and naval authorities are better able to judge than any private parties as to the places in which fighting is likely to occur. What is desirable is that people should be prepared to take up such enterprises if they become necessary in any locality in the future.

MILITARY HOSPITALS.

The recently instituted military hospitals, such as that at Stobhill, Springfield, Glasgow, are not under
the control of or supported by the Red Cross Society, has been equipped and are supported by the Government, while their sole management and control lie with the military authorities. There is no Red Cross hospital in Scotland at the present moment, nor will there be until the necessity for it is indicated officially by the military authorities. It is more probable that Red Cross units or even an hospital may be asked for abroad, and a large amount of money will be wanted for these.

**Dumbartonshire Doctors' Arrangements.**

The Dumbartonshire Branch of the British Medical Association has held a meeting in Glasgow with the County Panel and Local Medical Committees. It was unanimously resolved to recommend to all medical practitioners in the county that, during the war, wherever possible, medical aid should be given free of charge to the necessitous dependants of all men on active service at home and abroad; and, further, to suggest that the best way to carry this recommendation into effect would be by affording gratuitous attendance to such necessitous cases as are vouched for by the Soldiers' and Sailors' Families' Association or by its local committees throughout Dumbartonshire. A resolution intimating willingness to co-operate was also passed unanimously within the county was also passed unanimously. It was decided to assure those doctors in the county who have been or may yet be called up for service that the interests of their practices will be safeguarded by the Board of Health.

**National Health Insurance and the War.**

The Scottish National Health Insurance Commissioners have intimated that no arrears need be paid up by Reservists or Territorials on service. Their wives need not pay arrears on their behalf. While the husbands are serving, their wives will be entitled to maternity benefit, even if they are in arrears, provided the usual 26 qualifying contributions have been paid. No matter how great the arrears are, the maternity benefit is payable. Societies will continue to deduct pay made for maternity benefit even if, as in the case of a man who had remained ordinary employed contributors.

**LETTERS TO THE EDITOR.**

**Sir Victor Horsley and Forcible Feeding.**

Sir.—As a small and obscure one I have always felt a vast admiration for those that seemed really strong and deservedly prominent in our profession. I have been always greatly drawn to the personality of Sir Victor Horsley. I saw him show his strength at about the opening of my career in his fight against the fanatical—or perhaps maniacal—opponents of physiological research; I saw him standing alone as a strong man confronting the great gathering at the procession at Queen's Hall at the opening of the Insurance Act campaign. He has always seemed to me scientific, logical, and strong, and yet we now see him taking up an attitude in the forcible feeding question that seems a negation of all these qualities. It seems to show that there exists a great deal of humanity in mankind, and that the strongest man has a weak spot on his sentimental side through which he makes himself susceptible in the eyes of all those who have preserved their mental equilibrium in the controversy. Sir Victor Horsley's main arguments in his letter in your last issue seem to me to be simply fantastic. The Suffragettes demand the vote which Parliament refuses, and in fact claim that the State has no right to punish them when they attempt to coerce the law. The threat of law and terror. They say, in fact, that being convicted and sent to prison, they ought to be released because they attempt suicide.

It is the duty of the authorities to keep them in prison and prevent suicide, and when the attempt at suicide takes the form of a hunger strike they justly prevent it by forcible feeding. It is a grotesque quibble coming from an accomplished man of scientific intellect to suggest that the Suffragette deserves treatment any different to what would be meted out to an armed burglar or other criminal of the kind. The burglar has as much right to help himself to other people's goods by force as the Suffragette has to coerce the State into compliance with demands which they refuse. Sickly sentimentality is one of the many causes affecting our country during long years which have contributed to prevent any change on Empire and on the position in which we now stand. The sickly sentimental treatment of the Suffragettes has brought upon us the scorn of the civilised world, and has helped at least in some degree to imbue the foreign public with the belief that the Empire is no longer worthy to hold or fit to govern the vast domains across the seas over which the flag still continues to fly.

I am, Sir, yours truly,

**An Obscure Practitioner.**

**FORCIBLE FEEDING.**

**To the Editor of The Medical Press and Circular.**

Sir.—I fail altogether to follow Sir Victor Horsley's line of argument in the last number of The Medical Press and Circular. Sir Victor says: "Forcible feeding is certainly not employed as Dr. Sers asserts it is, to keep militant hunger-striking Suffragists alive, because if it were, then all such prisoners the latines are missing, including Mrs. Pankhurst, would have been killed." The fact that some are forcibly fed and others are not is in no wise controverts the truth of my statement, viz., that "they are fed to be kept alive," because in those cases where they are fed, the Government in their weakness have yielded to the "attempt to commit suicide," hence the necessity of forcible feeding, as in the case of Mrs. Pankhurst, does not arise. On the other hand, in those cases where refusal has occurred on the part of the inmates to themselves, acted with more resolution and determined to detain the prisoners alive in prison as long as possible, the necessity for forcible feeding does arise in order to prevent starvation. How, therefore, in the face of this can Sir Victor say an "error in my statement"?

I entirely agree with the Home Secretary and Sir Victor Horsley that forcible feeding is a most objectionable phase of the whole subject of starvation of any kind; but until some better method is discovered as a deterrent to homicide we retain it, notwithstanding its repulsiveness and objectionable features. The Governments all over the world are quite determined that we should retain to prevent starvation, and I venture to state it surpasses the wit of man to deal with voluntary starvation by any other method, unless possibly under some hypnotic process or "suggestion." May I ask Sir Victor, as he lays so much emphasis on the objectionable phase of forcible feeding, why the militants so directly concerned do not obviate the necessity for it by eating their food after the manner of human beings,payment with starvation for forcible feeding is in some sense "punitive," because it detains the militants in prison longer than convenient, and ensures for the time being their inactivity for further crime; but none save the most premeditated could conceive forcible feeding is resorted to in order to inflict pain. On the contrary, artificial feeding is incomparably less painful than hunger-striking, and I venture to state, as in the case of the present war, where a large number of cases has been discussed, the overwhelming majority would accept forcible feeding as an alternative to starvation if need be, even to the end of their days.

With respect to the trouble as to whether forcible feeding is "medical treatment" or otherwise, this appears to me arbitrary, but speaking for myself I should say forcible feeding in the hands or under the supervision of a qualified medical man should certainly be regarded as medical treatment, in the
same sense as artificial respiration in the case of a person all but dead from asphyxiation or through drowning would, if performed by or under the supervision of a medical man in time.

There is one question somewhat vague to me and which might open too wide a field for discussion which Sir Victor asks in the last paragraphs of his letter. He had better, I suppose, have replied to me irrelevant to my letter, and I have already encroached too much on your valuable space, so I would rather focus attention to my original and simple question—viz., *What do those who propose discarding artificial ventilation do as a substitute to prevent death from starvation?*

I am, Sir, yours truly,

CLEMENT H. SER.

5, Chancetby Road, Hove.  
August 27th, 1914.

REPORT OF SELECT COMMITTEE ON PATENT MEDICINES.

To the Editor of The Medical Press and Circular.  

Sir,—For my present knowledge of the above-named report issued on Wednesday last, I am indebted to the excellent summary in the *Times* of the following day. It is evident that the Committee is unanimous. The necessity for changing the law where it is alleged to be to the last degree simple and practical. The members of the Committee either alone or in combination will be able to make plain to the Government the urgent need for legislation; and there need be no doubt that, unless in the meantime we fall under the heel of Germany, we shall before long see an end put to a villainous traffic left too long immune against the law. It is a good deal more than 30 years ago that I began to help in exposing quackery. I always urged that the case for legislation was overwhelming and needed only exposure before some authoritative tribunal to compel the activity of Parliament. I advocated a Royal Commission; but I now see that the work was quite within the power of a Select Committee. The present Committee has dealt with only one half of the question; another Committee on the same lines is capable of dealing as deadly a blow at quackery as represented by fraudulent unqualified practitioners and those of their assistants who, as frequently happens, have been struck off the Register for infamous conduct, and yet go on practising screened by a quack.

I am bound to say that in the long fight against quackery the Medical Press and Circular has always stood in the front, and in spite of the apathy and even occasionally the sners of other medical papers has stuck to its guns in a righteous campaign.

SIR:—I have for some time past been engaged in a review of Select Committee leaves very little doubt that they are determined to see the matter through; but at the same time the profession through all its organised bodies ought to prepare to back them up in every possible manner. It was, I think, a great advantage that when I gave my evidence with regard to advertising, the Chairman of the Committee should have given place to the Hon. Harry Lawson, one of the proprietors of the *Daily Telegraph*. My evidence was printed, and I hope will be issued with the report. The long list of remedies the advertisement and sale of which the Committee advise should be prohibited will remove the last shred of excuse for newspaper proprietors; and it can hardly be doubted that there are, of course, a considerable number of people who are quite blameless—among the great papers that have up to now admitted objectionable advertisements will have to reconsider their position. It is the majority of the great papers that have done the least harm and have justified the law journals in more disgraceful methods including the insertion of puffing articles written and displayed in the style and place of editorial matter. I quoted to the Committee the statement made by one of the managing directors of a country newspaper company on the subject. He said they were a purely trading company, and it was out of the question that they could refuse quack advertisements which appeared in the majority of leading London papers, including most of those that set themselves up as exposures of humbug and fraud.

I am, Sir, yours truly,

THOMAS DUTTON, M.D.

London, August 24th, 1914.

— [Our correspondent will note that the statement to which he takes exception occurs in a "Letter to the Editor," which does not constitute an expression of editorial opinion.—Ed. M.P. and C.]

REVIEWS OF BOOKS.  

CLINICAL EXAMINATION OF THE BLOOD. (4)  

We are told that this small book is written with the idea of furnishing a very elementary guide to the most important and essential methods of blood examination regarded from the standpoint of the chemist and of the pharmacist.

There are three chapters—one on the blood film, one on haemoglobinometry and one on haemocytometry. Two very useful plates from Pappenheim's atlas are included. Only the methods preferred by Pappenheim are described. In spite of the elementary scope of the book it contains some strong features. Distinctions between cell types are drawn which are far beyond the realm of practical utility, and this appears to be admitted on page 36. On page 33 we are referred to the leucopenic type of leucocytosis and the leukemic form of leukemia. We are at a loss to know whether this is the wise type of nonsense or the nonsensical type of wisdom.

As a sample of the author's style we may quote the last paragraph—"The key to an increased anemic index in oligochromic oligochromatoma is the hyperchromatoma malformed cell." True, but not safe that we cannot establish whether the late Domine Sampson in ejaculating "Prodigious!"

(4) "Clinical Examination of the Blood and its Technique," by Prof. A. Pappenheim, translated and adapted by R. Donaldson, Bristol: John Wright and Sons, 1914. Price 3s. 6d. net.
PROBLEMS OF SCHOOL HYGIENE. (a)

This Conference was held at Edinburgh in May, 1913. It was attended by some seventy delegates from all parts of Scotland. Various subjects were discussed, such as the Hygiene of the School, the Medical Treatment of School Children in Towns, and Physical Education. Attention was given to the treatment of scabies and verminous conditions, very commonly presented by children attending Scottish Board Schools. Here the Board and the Public Health Department must co-operate. There are, in our experience, very few children attending city board schools whose heads are free from pediculi.

This is a matter calling for very stringent measures, much more so than we fear, is the case at present. This report is very interesting reading, but conferences of this nature do not give the full light of practical value when the suggestions given are acted upon. There is evidently a great amount of really good pioneer work being done by School Medical Officers, but much of it is necessarily hampered by conditions over which they cannot possibly have control.

SURGERY OF THE STOMACH, (b)

Good wine needs no bush, and this old axiom may be applied to Mr. Paterson's book on "The Surgery of the Stomach." That this work has been well appreciated by members of the medical profession is proved by the fact that the third edition of the work has already been exhausted. The popularity of the volume may be explained by the fact that it contains a remarkably clear exposition of the present situation of treatment of diseases and affections of the stomach from the surgical standpoint. For the eyes of the author are in some respects original and not in agreement with the opinions of the majority of surgeons. Mr. Paterson's conclusion in that the event of true pyloric obstruction the outlet from the operation of gastrojejunostomy is owing to functional changes and not solely to the formation of a direct passage from the stomach to the jejunum is dealt with at length, and his assertions to this effect are supported by examples and data drawn from his own experience. Undoubtedly the evidence he brings forward makes out a strong case for his contentions. To use a common English simile, "the proof of the pudding is in the cake." The author shows that his views are at least worthy of careful consideration. In the present edition the photographs illustrating the operation of gastrojejunostomy have been reproduced in pairs, and by using a stereoscope the minutiae of the operation are rendered exceedingly distinct. Plates from radiographs prepared by Dr. A. C. Jordan directing attention to the value of the method of diagnosing lesions of the abdomen have been also inserted. The practical charts for the orderly, e.g., as it does from the hands of a capable surgeon, are likely to be found; this, the second edition, to a still larger audience.

**LITERARY NOTES.**

Professor Calot's monumental work entitled "Indispensable Orthopaedics," with coloured plates and 1,252 illustrations in black and white, has now reached its tenth edition. The "Problems of School Hygiene" has already appeared in five different languages, and the present English edition is translated from the sixth French edition. It is written for general practitioners, and impresses upon them the necessity of beginning to treat all orthopaedic affections from the very commencement. It is divided into four parts dealing with acquired orthopaedic affections of a tuberculous origin, of a non-tuberculous origin, congenital orthopaedic affections, and an appendix. The splendid illustrations are quite a feature.

**"Keep Breathing: How to Do It and Why."** This short brochure, by Madame A. M. Carr, "Professor of Audiology, Voice Production, and Singing in All Branches," purports to be a textbook and guide to right breathing, singing, speech, and every purpose in life. The author states that the "key" to the initial method "came to her" in 1870 when she found the true way to restore her own voice and as she grasped the system, a great desire to tell others about it came to her, for she realised it was in the nature of a discovery—a revelation. This method of acquiring expression, which appears simple and easy, and really one begins to wonder, in view of this and other like "discoveries," whether the painful, laborious and expensive process by which a scientist is made is not indeed a work of supererogation? The method is arranged in the form of questions and answers, and the keynote to the so-called system propounded by the author is a knowledge of automatic deep breathing, which "consists in 'letting yourself breathe,' just as you 'let yourself live' as an infant."

Matthew's "Manual of Nursing Homes" is a concise guide to spas, health resorts and hydros of the British Isles, together with a list of nursing and mental homes. This book is similar to a great and little body in view is an endeavour to supply a handy reference manual for the use of medical practitioners and the general public. On the left-hand side of each page is a photographic reproduction of the health resort, arranged in alphabetical order, followed by a description of the chief attributes of each; the right-hand page is devoted to notices of the various homes and institutions, the whole forming a concise and comprehensive list of the information which one desires to see in such a work.

The guide fails in complete utility owing to the omission of practically all the nursing homes in the central part of London, not one of the well-known ones being included, and the same objection still is found in the almost universal absence of any indication as to fees in the case of private nursing homes, about which an intending patient usually desires exact information.

**"Auricular Flutter" is a pathological action of the auricles characterised by rhythmical coordinated contractions of their musculature at a rate that is greatly accelerated, usually between 250 and 300 per minute."** The term "auricular flutter," as applied to the human articles, is described for the first time by Laennec in 1811. The clinical disorder is identical with the flutter induced experimentally by MacWilliam, and the present work forms a compendium of everything worth knowing with regard to this condition of auricular acceleration. The physiological, pathological and clinical facts regarding this disorder, together with the features which distinguish it from other disturbances of the heart's action, are here clearly described by Dr. Jordan, and well illustrated by numerous electro-cardiograms and tracings.

We are glad to welcome the appearance of this book at the present time as an authoritative pronouncement on this very interesting and important type of clinical abnormality, of which we think those who may have had experience with it will find it most valuable, and we cordially recommend the work before us, as it embodies a carefully written statement of the extent of our present knowledge.
Criticalism of a Bone-setter.

An inquest was held at the Durham County Hospital last week upon a youth of seventeen who was injured on July 16th in a colliery. The father stated that his son told him that he was putting at a flat. An empty tub was to be taken to a heavy place on the face. In hand putting this tub he slipped and fell on his knee, bruising it, and he was afterwards taken to a bone-setter.

The Coroner: Why on earth should the boy be taken to a bone-setter with a bruised knee when he was being medically attended?

Dr. Hare said that what the bone-setter had done was to give the boy an inflamed joint. The leg was made a hundred times worse.

The Coroner declared that the inquiry showed how very foolish it was for people to go from a skilled medical adviser to an ignorant, unskilled man, who might fancy that he would be able to do it, and probably would be able if there were a dislocation.

The bone-setter had inflicted pain upon the boy and rendered the work of the skilled surgeon more difficult.

A verdict of "Death from heart failure following the accident" was returned.

A Sanatorium for Hull.

It is announced that the Hull Corporation have decided to borrow £14,438 for the erection of a sanatorium and hospital at Cottingham.

The Incorporated Sanitary Association of Scotland.

The fortieth annual Congress of the Incorporated Sanitary Association of Scotland will be held at St. Andrews from September 2nd to 5th. In a circular it is stated that the Council of the Association, acting in concert with the Town Council of St. Andrews, have decided that it is right, and indeed patriotic, to proceed with the business of the Congress as usual, but all the social functions which were arranged in connection with it have been cancelled. The business arranged in connection with the Congress will be a lecture on "Health and the State," by Dr. W. Leslie Mackenzie, medical member of the Local Government Board. Mr. Francis Braid, sanitary inspector, Kirkcaldy, in his presidential address, will deal with "The Housing Problem as it presents itself today," and "The need of a sanitary definition and fixed standard for milk," will be introduced by Mr. W. W. Kelso, sanitary inspector, Paisley.

Other subjects to be discussed are "The handling and distribution of milk at railway stations and the inroads about disinfection," and "The question of establishing a uniform system and standard of meat inspection."

MEDICAL WAR ITEMS.

The following resolution has been passed by the Chadwick Trustees:—That in view of the immense importance of encouraging in every way the promotion of careful sanitary organisation in the naval and military services during the present campaign, the Chadwick Trustees have resolved, under the powers conferred upon them under the Scheme they administer, and under the provisions of their indenture to award at the close of this year the Chadwick Gold Medal to £50 each to the naval and military Medical Officer respectively in the British service who shall have distinguished himself most in promoting the health of the men in the Navy and the Army. The nomination for such presentations to be, as provided by the terms of the Trust, by the Directors-General of the Naval and Military Medical Services respectively.

The Board of Chadwick Trustees have also making arrangements for providing, or assisting in the provision of, lectures and demonstrations on naval, military and hospital hygiene. Particulars of these lectures will shortly be announced.

It is good news to hear that "Salicine," which was referred to in the "Confidential Circular" addressed by H.M. Government to the medical profession as being in short supply in the salicylic group, is now guaranteed by the British manufacturers to be sufficient for at least two years' normal consumption.

Two hundred beds are at the disposal of the Admiralty in the Dreadnought Hospital at Greenwich for the reception of sick and injured who may arrive in the Thames at any moment from the Fleet. These beds are fully equipped and in close proximity to the operating theatres, etc.

The Cambridge Research Hospital, through the generosity of Mr. Otto Beit, has been offered to the War Office as a completely equipped hospital for sick and wounded medical, surgical, and nursing staff for 20 beds. The War Office have intimated that they will be glad to avail themselves of this offer should additional hospital accommodation for officers be needed.

The Queen Victoria Memorial Hospital at Nice, of which Sir George White, of Bristol, is the Chairman, has been placed at the disposal of the French Government for the reception of wounded officers.

Sir Thomas Shangnessy, President of the Canadian Pacific Railway Company, has offered on behalf of his company, a ship to be equipped and opened as a hospital by the Women's Empire League.

The Council of the Royal Institute of Public Health has placed its laboratories at the disposal of manufacturers and others who wish to avail themselves of the Institute's bacteriologists and chemists.

The British Field Hospital for Belgium, which is recognised by the War Office and is officially under the Belgian Red Cross organisation, has an honorary staff of 600 doctors and 400 nurses. The equipment includes 40 beds for wounded, X-ray apparatus, motors, ambulance cart, and four horses, and every requisite for hospital and emergency work.

With the object of giving financial assistance to the British Red Cross Society, Red Cross stamps in six different designs have been prepared, and a first issue of them, the 200 million stamps has just been put into circulation. The disposal of the committee free of cost. The stamps will be sold at a halfpenny each or threepence per set of six different designs.

A hospital of 200 beds, known as the "Allied Forces Base Hospital," under the charge of Major Ernest Miles, F.R.C.S., Surgeon to the Cancer Hospital, has been fully equipped and is ready to start for any locality on the Continent which the military authorities may deem advisable.

The number of wounded British soldiers back from the front up to Tuesday morning last is stated as follows:—500 in the Royal Herbert Hospital at Woolwich, 316 in the London Hospital, 100 at Plymouth, and 140 at Cheltenham. The number of British wounded in the legs and feet, and, with the exception of some at Woolwich, there are few serious cases.

NOTICES TO CORRESPONDENTS, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 25s; post free at home or abroad.
Appointments.

New York 18 of the Royal College of Physicians, London, M.D. Lond., B.M., F.R.C.S., R.C.S., R.C.S., L.R.C.P., R.C.S., E. B. and R.C.S., for a daughter of John Edele. The University of Sheffield—Department of Pathology—Junior Demonstrator in Pathology, Salaries £200 per annum, with board, apartments, and laundry. Applications to W. A. W. Price, F.C.S., Secretary.

BIRTHS.

CON—On August 25th, at Bromee Place, Norfolk, the wife of Ivo Geake Cobb, M.D., of 10 Seymour Street, Portman Square, of a daughter.

BEATTY—On August 27th, at Craigirr, Banffshire, the wife of Samuel Beatty, M.B. and C.M.Edin., of a son.

BROWNLOW—On August 27th, at Ambleside, in the County of Westmorland, the wife of William M. Brownlow, R.S., of a son.

CHRISTIE—On August 25th, to Dr. and Mrs. Brian Crichton, 59 Park Lane, Croydon—son.

EARLE—On August 26th, at 33 Clevendon Mansions, Highgate Road, N.W., the wife of John Grundy, M.B., of Middlesex Hospital, of a son (John Esmon Grundy).

GEORGE—On August 27th, at 17 Upper Wimpole Street, W., the wife of Cecil Graham, F.R.C.S., of a son.

LAWYALL—On August 23rd, at 38 Linthorpe Road, Middlesborough, Hugh, the wife of Major F. W. Lawall, R.A.M.C., of a son.

MATHER—On August 24th, at the Medical Officer's House, H.M. Hospital, Whitehall, London, the wife of Thomas Mather, M.R.C.S., L.R.C.P., for a daughter.

RAINEY—On August 25th, at Wakefield House, Crompton Street, Eastbourne, the wife of E. Holmes Rainey, F.R.C.S., of a daughter.

WATERFIELD—On August 27th, at Strathie House Beccles, to the wife of E. Noel Waterfield, F.R.C.S., Sudan Medical Service—Wilson—On August 28th, at 66, Holland Park Avenue, W., the wife of J. Horne Wilson, M.D., of a son.

Marriages.

HARBISON—HULK—On August 26th, at Harwich, very quietly to the war, Staff Surgeon William Rhodes Harbison, Royal Navy, to Irene Woodworth, only daughter of Mr. R. M. and Mrs. M. R., of Bury St. Edmunds, Suffolk, £180 per annum, with apartments, and board. Applications to the Secretary, Hulme Dispensary, Dale Street, Stretford Road, Manchester.

MELLADREW—RAIN—On the 24th inst., at Christ Church, Mayfair, Henry Frederick Lawatson Meldrew, late Surgeon Lt.-Col., Royal Horse Guards, to Elizabeth Mackenzie Rain, a daughter of the late Rev. William Rain, D.D., Stowe-Smyth for the 15th August, at Hommony Abbey, New Forest, Douglas N. Smith-Smith, B.A., M.C.(Canb.), M.R.C.S., L.R.C.P., only son of Newton Smith-Smith and the late Mr. and Mrs. Smith, of a daughter, to Hetty Mary, only daughter of Robert Gilman and Miss. Lilian, of Hythe, Southampton (formerly of Sunapur, Assam, India).

SCHMANN—BROOKS—On August 27th, at St. Mary's Church, Twyford, in the county of Berkshire, to the daughter of Sir Walter and Miss. Homerville of London, Canon, of a daughter, to Mr. and Mrs. John W. Hamilton, of London, M.R.C.S., L.R.C.P., of Erchifield, Henley-on-Thames, to Lena Mary, only daughter of the late Dr. Brancky and Mrs. Brancky of Henley.

TRENT—MACKEZIE—On August 25th, at the United Free Church, Torquay, to the daughter of Mr. and Mrs. Thomson of London, to Henrietta Mary, of the Indian Medical Service, to Isabel Blanché, eldest daughter of the Rev. D. F. Mackenzie, B.D., Tain.

Deaths.

BAIN—On August 24th, 1914, at Strathtiber, Harrogate, Leslie Cortis, younger son of Dr. and Mrs. Bain, aged 18 years.

HAMILTON—On August 27th, at his residence, Maghera Burry, Portrush, Robert Hamilton, Esq., F.R.C.S., late of Liver- pool, aged 87.

HENDERSON—On August 27th, at Impendle, Natal, South Africa, Dorothy Winifred Feather, only daughter of Dr. William Warner Henson, and second daughter of the late C. M. Major, of South Africa, aged 25 years.

HELZ—On August 25th, at his residence, St. Domingo, Beach Road, Hove, Charles Alexander Hill, M.R.C.S., L.R.C.P., of 13, Upper Street, Liverpool, aged 47.

WEIR—On August 31st, at 15, Espanade, Waterloo, Dr. Arthur Weir, Physician to the Late Dr. Shakespeare, Liverpool, aged 59 years.

HULME DISPENSARY.

Dale Street, Stretford Road, Manchester.

WANTED A HOUSE SURGEON duly registered and fully qualified. Salary £180 per annum. Annual increase to £200 with accommodations, with testimonials, at once to Honorary Medical Secretary.
NOTES AND COMMENTS.

The first great battle has resulted in a casualty list of between 5,000 and 6,000 British troops. This loss occurred in the course of continuous fighting for four days or more, during which our force appears to have retreated gradually and in good order over a distance of thirty miles or upwards. Details of the conflict are necessarily meagre at this stage of the proceedings, but one need not turn to newspaper accounts to realise that an enormous stress must have been thrown upon the Army Medical Service in dealing with large numbers of wounded men amid the confusion of a retreating army in continuous action. It is gratifying to note that within a few days many slightly wounded men were landed safely in England. Accounts have come of others who travelled long railway journeys with little or no food, and found difficulty in securing sea transport on reaching the French seaboard. The matter was very properly brought forward in the House of Commons, and was answered by Mr. H. J. Tennant on behalf of the Government. He stated that elaborate arrangements had been made for the rapid transport of wounded soldiers, and suggested that any difficulties that may have arisen were due to the soldiers having gone to ports other than those officially prepared for them. At the same time his attitude was more or less resentful of criticism—an official position that calls for some little comment.

The Duty of a Medical Journal.

The duty of a medical journal is clearly to point out any defects that are due to lack of foresight or bad administration. To do otherwise would be to foster that fool's paradise in which the War Office of former days was wont to pass its days. As a matter of fact the present system shows an almost incredible advance in efficiency since the Boer War, in which we were engaged a few brief years ago. The Army Medical Service, in point of fact, has shared to the utmost the general advance towards scientific and businesslike efficiency that has transformed the military service of the United Kingdom. The conditions of warfare have undergone a great alteration. The size of the modern army has been multiplied five-fold to seven-fold, or even more—a fact that has a weighty medical significance. Long range weapons and high explosives—not to mention the advent of aerial warfare—have modified to a great extent the nature of the injuries sustained. Then again, so far as the medical service is concerned, the personal risk to stretcher-bearers, and to surgeons and nurses at or near the fighting lines, is probably far greater than that to which they were exposed under former conditions. At long range it is obviously difficult or impossible to avoid hos-
NOTES AND COMMENTS.

Sept. 9, 1914.

The Medical Press.

The foregoing paragraph anticipating heavy losses was written on Wednesday, September 2nd. On the following day appeared a detailed official first list of casualties, among British officers. The number killed was 35, wounded, 52, and missing; and the list appears to be incomplete. It seems, further, not unlikely, considering the deadly nature of the conflict, that the "killed" will in the end be considerably augmented. Reports as to German barbarity in the field have been so continuous, so detailed, and given on such responsible authority that officers, however cautious, are not likely to avoid the conclusion that the enemy kill—in other words, murder—many of the wounded. If that be so the probability of a large proportion of the "missing" being really dead is correspondingly increased. The fact has an important bearing upon the losses reported in the Royal Army Medical Corps and Army Medical Service Corps of the Allies. Although there were 76 killed, one was wounded and thirteen missing. In other words, a fourth of the total came from the medical branch. To some extent this disproportionate loss may be accounted for by the fact that as our troops fell back R.A.M.C. officers were left behind in charge of wounded men under the protection of the Red Cross. This list, it must be remembered, refers simply to the first part of the great battle begun at Mons on August 23rd, and gives no indication of the more or less continuous fighting that has taken place in the stubborn falling back of the Allies upon Paris before the overwhelming forces of the German Army.

The ruthless way in which the Germans are carrying on the war is testified to by many War Correspondents. In all wars a certain amount of barbarity must be expected, but in the present instance so many accounts have come from responsible quarters of the killing of the wounded, of the massacre of non-combatants, including women and children, of reckless firing, sack, pillage, and wanton cruelty that it is impossible to doubt its existence. Apart from the evidence of the witnesses, there is the silent testimony of devastated villages and towns burnt and depopulated. The destruction of the university town of Louvain, the Oxford of Belgium, with the loss of its priceless treasures of art, its ancient records, its magnificent library, and its splendid buildings fastens for all time an stain upon the Kaiser Wilhelm the Second. With regard to this deplorable event, the University of Ireland has adopted and placed on record the following resolution:—"The Senate of the National University of Ireland desires to offer to the illustrious University of Louvain its deep sympathy in the calamity which has befallen her, and to place on record a protest against any act so disastrous to the progress of mankind." It is to be hoped that this spirited protest will secure world-wide sympathy and approval. Now that the "Call to Arms" is resounding through the length and breadth of the land, the question of the physical fitness of candidates for the ranks looms large among others of equal importance. It is astonishing how many persons who believe themselves to be sound in wind and limb present, after due medical examination, some physical defect which, if not serious enough actually to debar them from enlisting, may prove a material drawback in the testing time of real warfare. Hence the strictness with which the medical examiner performs his duties. It is a mistaken kindness and an unwise patriotism that would pass a man with bad dentition or whose hearing is defective, though the man-in-the-street, in his eagerness to come forward, may think otherwise. Several of the dental schools and dental departments of the medical schools, as well as private dentists, have agreed to render free conservative treatment to recruits whose poor dentition has been the cause of their rejection. It permits of the assembling of a series of dental treatment all well and good, but under the pressure of existing circumstances it may be allowable to relax the usual strictness regarding this part of the examination, greater attention being paid, meanwhile, to the candidate's sense of sight and hearing. A sound heart and a keen eye plus good health and fair muscular development will ceteris paribus more than atone for a slight dental shortcoming. The marvellous response of the nation to Lord Kitchener's appeal for soldiers has thrown a light on our national character. Recruits have flocked literally in tens of thousands to the various stations. In London complaints have been made of the delay in medical examination, due to the paucity of medical men appointed to that special duty. With every appreciation of the sudden stress thrown upon the Army Medical Department and the marvellous competence they have shown in their organisation on a war footing it may nevertheless be permitted to make a few comments upon this quite understandable and minor defect. The cause of the trouble being a lack of medical officers, why should not sufficient numbers thrown upon the Army Medical Department?
by experience to discharge the responsible duty of the medical examination of recruits. As a matter of fact the War Office could get a hundred medical men offhand in London alone, many of them qualified by hospital and military experience for the work, and capable of the precise application of any standard fixed by the War Office. Many asylums, which had been taken for the work, would be spared the many hours and many days of weary waiting and consequent discouragement to which they are at present subjected. It is clear that all avoidable obstacles should be as far as possible removed from the path of the men who are so nobly responding to the call of their country, and it is with this point in view that these remarks are offered for Lord Kitchener's consideration. As a matter of fact a fee of half-a-crown is payable for each examination, and it is of course impossible to think that there is any objection on the part of the War Office to pay civilians.

The full results of the war upon the profession will not be fully realised for some time to come. For years past it has been customary to bewail the redundancy of medical men—and without doubt there was a good deal of truth in the general belief. Now there is likely to be a shortage for several years to come, and this will probably lead to an increase in the number of students. There seems to be a tendency to better remuneration of medical services in more than one direction. The National Insurance Act has affected an enormous improvement in the income to be derived from practice amongst the poorer classes. Not only is the panel doctor able to command, sooner or later, a fair and sometimes a large income from insurance practice, but payment is moreover guaranteed by the State. Then again, thanks to the efforts of the medical profession, the remuneration of many public appointments has been maintained at a fair standard. It is not unlikely that the rates of pay in the Government services may be raised before long and that after the present war there will be a permanent increase in the staffs of the army and navy medical service.

The war has already absorbed a large proportion of what may be termed the floating section of the medical profession—that is to say, those of its members who are not engaged in private medical practice or in one of the public services. Many newly qualified men are resident in hospitals, where they gain a valuable insight into professional work. Others of various ages act as assistants or do locum tenens work. Naturally many of this class have joined the army as surgeons on the comparatively liberal terms offered for service during the war—namely, twenty-four shillings a day, with allowances, and a grant at the end of the term of service. In addition not a few practitioners have thrown up their work and gone to the front. A large number of hospital surgeons have followed their example, with the result of a serious dislocation of medical practice throughout the Kingdom. Before the war there was a shortage of medical men, and has now been seriously aggravated. Many asylums, poor law infirmaries and voluntary institutions are at their wits' end to find resident medical officers to carry out their routine work.

Brighter Financial Prospects.

The German Drugs.

It is evident that a good deal of inconvenience may be caused by the stoppage of supply of various synthetic and other drugs derived from German sources. In some instances the drugs are manufactured entirely in England, and if their use be discontinued by medical men their action will tend to throw a number of their own countrymen out of employment. In other cases, the nature of a trading name of Teutonic aspect is apt to give rise to an entirely mistaken conclusion. As an example may be taken the Hoffman-La Roche Company who have written us to say that although they have works in Baden yet their head office and laboratory are in Basle, Switzerland. This firm announces that it has large stock in England, and will have no difficulty in fulfilling orders now or at any future period. This point suggests another fact that medical men in the United Kingdom will do well to consider before finally deciding to delete drugs of near or remote German origin. The point is that many English firms hold large quantities of such remedies and it is again our countrymen who will suffer if they are left unsold. The best plan will probably be for our medical men to go on prescribing whatever drugs may be in their judgment most suitable for their patients, regardless of the country from which they have come. It would be little more logical, to put a ban upon German music, or to resolve in future to disregard all scientific research work: "Made in Germany."

PERSONAL.

The King and Queen went to King Edward VII's Hospital for Officers in Grosvenor Gardens to visit wounded officers who have arrived from the front.

Dr. Frances Ivens will deliver the Inaugural Address at the London School of Medicine for Women in October next.

Sir Victor Horsley, F.R.S., will deliver the William Mitchell Bankes Lecture in the University of Liverpool on October 9th.

Professor Arthur Keith, M.D., F.R.S., will deliver an address at the opening of the winter session of the Medical School of the University of Leeds.

Dr. C. Hubert Bond, Emeritus Lecturer in Psychiatry, will deliver an address upon the occasion of the opening of the winter session at the Middlesex Hospital.

Surgeon-General Sir Anthony Dickson Home, V.C., K.C.B., M.D., aged 87, of 7 Palace Gardens Terrace, W., a Crimean and Indian Mutiny veteran, successively Principal Medical Officer in Ashanti, in Cyprus, and in India, left estate of the gross value of £24,907.

Major F. S. Irvine, R.A.M.C., whose name appears among the "Missing" in the recent battle at Mons, took part in the famous siege of Ladysmith, and was also in the action of Spion Kop, Vaal River, and Heights, as well as in subsequent actions in the Orange River Colony.

Note.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by E. Arthur Dorrel, F.R.C.S. Eng., Assistant Surgeon Royal Eye Hospital. Assistant Ophthalmic Surgeon, Prince of Wales's Hospital, etc., etc. Subject : "Lachrymal Obstruction."
EDUCATIONAL SUMMARY FOR 1914-15.

INTRODUCTORY REMARKS.

With the advent of each October and the opening of the winter session of the medical schools, it is the custom of the leading medical journals to issue a special students’ number dealing with matters of current and potential interest to those about to join the ranks of our great and learned profession. The following remarks have been drawn up with that end in view, and are offered in a spirit of full sympathy with the aspirations that should inspire the will and determination of all students who have chosen a career in medicine.

The necessity of a wide culture is registered in the scope of the preliminary examination. For those who aspire to its highest honours it is necessary to possess a knowledge of many things outside medicine, and above all to acquire an intimate acquaintance with men and manners. Happily, this does not mean that the aspirant must needs have a University training, for some of the men whose names are household words in the profession have not enjoyed that advantage, while others have started from the lower steps of the social ladder. The prizes of the profession, in fact, are open to all, assuming, of course, that they are able to obtain an adequate preliminary education and the funds necessary to meet the expenses of qualification. Of late years the tendency has been to include in the preliminary examination subjects that would be of direct use to the student in his later career in the schools. It would be difficult to imagine a better training for a young man than that required in mastering the elements, say, of botany, zoology, and chemistry. At the outset of our remarks it has seemed natural to dwell upon the intellectual side of the career of medicine, for in that will be found a solace for the trials and difficulties that must be faced in that as in all other walks of life. From the monetary point of view it is open to any man of ordinary gifts and application to secure a competency, although he may have at first to go through a more or less extended period of years spent in the weary task of waiting for practice.

It has been our duty year after year to warn those entering or about to enter the medical profession that they must not, as a rule, expect to make a fortune. There are prizes not only for consultants and specialists, but also for general practitioners, but undeterred success and competency must be the lot of the majority in all branches of practice. During the past twelve months, however, as pointed out in our opening columns, the financial conditions of practice have considerably improved. A vast amount of work amongst the poorer classes that prior to the National Insurance Act was performed either gratuitously or at contemptibly low rates, is now paid for handsomely by the State. At the same time the general rate of friendly society and Poor Law appointments has been generally advanced, thanks to the self-protective efforts of the profession itself. National insurance has had an effect upon the hospitals, the full extent of which it is not yet possible to estimate. The total number of patients in voluntary hospitals has diminished, and their income has in not a few instances also decreased. The working of the Act has placed the members of the honorary hospital staffs in an anomalous position. By attending to insurance patients without fee they are doing service for which the State has contracted to pay. There can be little doubt that sooner or later this unsatisfactory state of affairs must be readjusted. The Chancellor of the Exchequer cannot, and it may be readily believed, does not wish to throw any part of the responsibility of insurance medical work upon voluntary charity. Hospital surgeons, physicians and specialists, again, have undertaken to give their services to poor persons subject to certain charitable regulations, but their agreement certainly does not cover attendance upon insurance patients. In the case of the small hospitals, the hardship inflicted under the Act is great, inasmuch as they find themselves depleted in patients and in funds, with no compensatory prospects at the hands of the State that has dealt them so staggering a blow. Treating the situation more generally, it seems fairly evident that national insurance constitutes a considerable advance towards the institution of a system of a State medical service. Another step in a similar direction will be the enrolling of the voluntary hospitals in the national insurance organisation. This consummation, however, is not likely to be attained in any near future. The student who intends to devote himself to those higher branches of medical practice in which a hospital becomes a necessity would be well advised to keep a careful eye on the conditions of such posts, whether in general or in special hospitals.

There are other fields of civilian practice to open to the qualified practitioner.

Such, for instance, is the school medical service and the greatly increased and partly specialised Poor-law medical service. In any case, a State appointment of the kind, however irksome and tedious, must rank immeasurably higher than the open dispensary practice with its degrading circumstances. It is indeed deplorable to find a member of a learned and honourable profession offering physic and advice for sixpence, or even threepence a consultation. In the course of time, however, we may hope that the conditions of this kind of undesirable medical practice is the outcome may be removed, and that there will be no need for any qualified man to adopt such discreditable methods.

From the first day that he commences his medical studies the student will do well to keep steadily in view the necessity for keeping abreast of new ideas. The present age is one of thinkers, and it is filled with fresh ideas in all branches of intellectual activity with an exuberance that has never been equalled at any previous period of human history. Above all is this true in medicine. The student of a generation ago finds himself surrounded with a host of new methods, remedies and appliances, the very jargon of which demands for its interpretation the brains of a general specialist. Today the private practitioner must have a knowledge of vaccines, of many laboratory methods of diagnosis, and of a long list of technical processes, or, at any rate, of their principles and their practical application, as, for instance, the culture of the Wassermann test for syphilis and the treatment of that malady by Ehrlich’s famous “606.”

In all classes of practice the need of the pathologist is everywhere more apparent. So great, indeed, has become the necessity that we were lately informed on
good authority that a famous German physician had a full clinical examination made of each patient before the latter entered his disease and the immediately made him, The student, being in mind, will do well to pay careful attention to the acquirement of a working knowledge of the main methods of the clinical and pathological laboratory. At the same time, it cannot be too strongly impressed upon him that it is necessary to cultivate the habit of close bedside observation of his patient. It is impossible to replace by the text and the microscope that carefully trained faculty which an aptitude in clinical science, the presence of which not infrequently determines the success or failure of the medical man in his professional career. It should be remembered that the conditions of actual practice clinical is the only place where the student meets well-appointed hospital. In dealing with private patients the practitioner is thrown upon his own resources, and may have to meet serious casualties and emergencies with the slenderest of surgical and medical resources. An extreme instance of the kind is when a medical man is called upon to treat a foreigner in extremis unprovided with a stethoscope or any other professional appliances, and unable to communicate directly or indirectly by the aid of friends the patient or his friends. Under such circumstances the diagnostic faculties of the medical observer are put to a cruel test. A medical man's fortune sometimes is when a medical man is called by the police to an unconscious patient. An error in the diagnosis of alcoholism or other narcotic poisoning, fractured base of skull, concussion, diabetic coma, apoplexy, and so on may destroy the patient's chance reputation, whilst others are seeking to attain that enviable notoriety, and while some men may be attracted by the spirit of adventure to cast in their lot with the new and struggling, others will prefer the security and prosperity of an established practice. This number of The Medical Press and Circular is to present impartially the claims and attractions of all schools, and if parents and their wards study its pages carefully they will, we feel sure, be convinced that there are none that have not their own special charms. The outlay on actual necessary educational expenses does not differ materially in different places, the higher cost of certain centres being chiefly due to the greater cost of living. It is obvious that in London, for instance, the outlay on actual necessary educational expenses must be considerably more than in many smaller and less favourite towns. While, on the contrary, a student living in his parents' home in London will not be so much expense to them if he goes to a distant University as if he takes up a single room at the Northern University. But, other things being equal, it is important for the average student to choose that school at which he is most likely in after years to obtain a resident post.

CHOICE OF A QUALIFICATION.

One day, in the not very distant future, we hope, the choice of what qualification to study for will not present so many difficulties as it does today. The student will be faced with the haphazard way in which British institutions and customs grow up, there have come into being a number of rival interests, both pecuniary and scholastic, which it is difficult to break down, with the result that students are faced with all sorts of qualifications, according to their own taste almost every conceivable alphabetical combination to their names.

It may be laid down in general terms that the shortest and least picturesque of these designations will generally be sought after, the student being under the impression that the expenditure of time that it will save in signing certificates, and in the greatest ease by which it will be understood of the people. Happily, or unhappily, a qualification is less the handicap of the career, as a rule, but small relation to success in practice, and practitioners of light and leading will be found to have laid the foundations of their success on a more solid basis than that of academic triumph.

COURSE OF STUDY.

Although there are certain individual variations, the course of study pursued at all the medical schools is pretty much the same. One or two of the University

CHOICE OF A SCHOOL.

Many things are concerned in the choice of a school. Tradition, family influence, proximity, means, and acquaintance with other students or members of the staff all come into play, and there are few who are not affected by them. The would-be student, however, has to the whole matter a not to mention the qualifications himself and his selection unhampered by other consideration that that of merit, has the choice of nearly twenty centres in which to follow his best. There is a natural tendency for a man to look to his immediate vicinity for the maturing of his genius, and in these days, when Universities are cropping up with bewildering frequency, most students will probably find one within fifty or sixty miles of their homes. As the medical curriculum is a long one, and not necessarily by the official Medical Council, there is not much variation in that of the individual schools, and a good all-round education can be relied on in practically every one. On the one hand, some have teachers of established ability and reputation, whilst others are seeking to obtain that enviable notoriety, and while some men may be attracted by the spirit of adventure to cast in their lot with the new and struggling, others will prefer the security and prosperity of an established practice. This number of The Medical Press and Circular is to present impartially the claims and attractions of all schools, and if parents and their wards study its pages carefully they will, we feel sure, be convinced that there are none that have not their own special charms. The outlay on actual necessary educational expenses does not differ materially in different places, the higher cost of certain centres being chiefly due to the greater cost of living. It is obvious that in London, for instance, the outlay on actual necessary educational expenses must be considerably more than in many smaller and less favourite towns. While, on the contrary, a student living in his parents' home in London will not be so much expense to them if he goes to a distant University as if he takes up a single room at the Northern University. But, other things being equal, it is important for the average student to choose that school at which he is most likely in after years to obtain a resident post.

CHOICE OF A QUALIFICATION.

One day, in the not very distant future, we hope, the choice of what qualification to study for will not present so many difficulties as it does today. The student will be faced with the haphazard way in which British institutions and customs grow up, there have come into being a number of rival interests, both pecuniary and scholastic, which it is difficult to break down, with the result that students are faced with all sorts of qualifications, according to their own taste almost every conceivable alphabetical combination to their names.

It may be laid down in general terms that the shortest and least picturesque of these designations will generally be sought after, the student being under the impression that the expenditure of time that it will save in signing certificates, and in the greatest ease by which it will be understood of the people. Happily, or unhappily, a qualification is less the handicap of the career, as a rule, but small relation to success in practice, and practitioners of light and leading will be found to have laid the foundations of their success on a more solid basis than that of academic triumph.

COURSE OF STUDY.

Although there are certain individual variations, the course of study pursued at all the medical schools is pretty much the same. One or two of the Universi-
THE ENGLISH UNIVERSITIES.

The English Universities, including Wales, are seven in number—viz., Oxford, Cambridge, Durham, Manchester, London, Sheffield, Birmingham, and the University of Wales. The choice of a University is usually determined by social, geographical, and financial considerations. Students whose parents are able and willing to spend the necessary sum will do well to select one of the ancient Universities, since their degrees confer upon their holders a status not accorded by the public to the degrees of more modern institutions. To those less favoured by wealth but blessed by intelligence, the London University offers ample scope, and its degrees are recognised as the outward and visible sign of high professional attainment. A capable and industrious student, however, may equally well lay the foundations of success in one of the newer Universities.

UNIVERSITY OF OXFORD.

There are two degrees in Medicine, B.M. and D.M., two in Surgery, B.C. and M.Ch., and two diplomas, Public Health and Ophthalmology.

Graduates in Arts (B.A. or M.A.) are alone eligible, except for the Diploma Examinations. To obtain the B.M., B.C., M.D., or M.Ch., candidates must have passed 1. Preliminary Mechanics and Physics, Chemistry, Animal Morphology, and Botany. 2. Professional. (a) First Examination: (1) Organic Chemistry, (2) Human Anatomy. (b) Second Examination: (1) Midwifery, (2) Pathology, (3) Forensic Medicine with Hygiene and (4) Materia Medica with Pharmacy.

The First Examination for B.M. and B.C. may be passed as soon as the Preliminary Scientific Examination is completed. The subjects may be presented separately or in any combination in any order, provided Anatomy and Physiology be passed together.

The Second Examination may be passed after the completion of the first, but Pathology and Hygiene may be taken before or with the remaining subjects. Before admission candidates must present certificates of attendance on a laboratory course in Practical Pathology and Bacteriology and of having acted post-mortem clerk for three months, surgical dresser for six months, and clinical clerk for six months. Also they must produce certificates of instruction in Infectious and Mental Diseases, and of attendance on the curriculum of the course on Vaccination and the administration of Anaesthetics. Also in respect of the First Examination candidates must present certificates showing that they have dissected a sufficient number of human and animal corpses and attended courses of laboratory instruction in Practical Histology and Physical Physiology.

The degree of D.M. is granted to Bachelors of Medicine of the University provided they have entered their thirtieth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners whose subject is dealt with. A book published within two years of the candidate's application for the examination for the degree may be substituted for a dissertation. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twelfth term.

Diploma in Ophthalmology. — There is an examination once in each year in the Theory and Practice of Ophthalmology for the purpose of granting certificates of proficiency therein, styled Diplomas in Ophthalmology. A candidate must have entered two years at the University, and is eligible to the examination conducted by the Board of the Faculty of Medicine, which has power to make regulations as to the subjects of the examination, the time at which the examination is held, and the conditions of admission. No candidate is eligible to the examination for the diploma who has not passed at Oxford a course of study in Ophthalmology approved by the Board of the Faculty of Medicine, and extended over a period of at least two years.

Travelling Fellowship, Scholarship, and Prize. — The Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for three years and is of the annual value of £200. Application should be made to the Radcliffe Examiners, Radcliffe Library, University Museum. A Rolleston Memorial Prize of £50 is offered to a candidate who has been two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing and who have passed all the Exams. for the degree of B.M. or B.A. for an original research in some Biological science. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially for research in some branch of medical science. The Theodore Williams Scholarships of the value of £50 each are awarded to students in the subjects of Anatomy, Physiology and Pathology.

Detailed information may be obtained from the University Calendar.

UNIVERSITY OF CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the University, and have passed the previous examination in classics and mathematics. There are three examinations: The first in (1) chemistry, (2) physics, and (3) biology; the second in (1) human anatomy and physiology, and (2) elementary pharmacology including pharmaceutical chemistry and the elements of general pathology; and the third in (1) surgery and midwifery, and (2) principles and practice of medicine. The first examination is divided into three parts, and the second and third examinations each into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept containing the outline of the thesis followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery after passing the third examination for Bachelor of Medicine.

The M.D. degree may be taken three years after the M.B. An Act must be kept, including the presentation of an original thesis, with oral examinations and an essay to be written extemore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C. or being M.A. has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submit a thesis showing that he has acquired that science in the art or art of surgery. The yearly expenditure of a student who keeps his terms by a residence in a college is from £150 to £200 a year. This, however, may include all payment made to the University, and he also has to meet living costs, clothing, officer money, travelling expenses, &c. Non-collegiate students have to pay the University fees only, which are not large. They lodge and board in the town; their expenses, therefore, are largely in their own hands. Various scholarships, prizes and medals are open to medical students.

The University grants a diploma in public health without the necessity of residence, the examination being in so much of State Medicine as is comprised in the first year of the officers of public health and public health practitioners. The University requires the candidate to present to the Society in their applications to the Secretary of the Annual Report of the Medical Officer of Health.

These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the "Medical Register" of the United Kingdom, and not be members of the University, may send in their applications to the Secretary of the State Medical Officer of Health. In the examination the candidate is required to answer as many questions as are on the examination paper under certain conditions as to previous study and experience. Successful candidates receive a University Diploma.

The Radcliffe Examiners, Radcliffe Library, University Museum. A Rolleston Memorial Prize of £50 is offered to a candidate who has been two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing and who has passed all the Exams. for the degree of B.M. or B.A. for an original research in some Biological science. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially for research in some branch of medical science. The Theodore Williams Scholarships of the value of £50 each are awarded to students in the subjects of Anatomy, Physiology and Pathology.

Detailed information may be obtained from the University Calendar.

The Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for three years and is of the annual value of £200. Application should be made to the Radcliffe Examiners, Radcliffe Library, University Museum. A Rolleston Memorial Prize of £50 is offered to a candidate who has been two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing and who has passed all the Exams. for the degree of B.M. or B.A. for an original research in some Biological science. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially for research in some branch of medical science. The Theodore Williams Scholarships of the value of £50 each are awarded to students in the subjects of Anatomy, Physiology and Pathology.
An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registrar, Cambridge. Full information is contained in the University Calendar. The Students' Handbook to Cambridge may also be consulted.

**UNIVERSITY OF LONDON.**

The University of London became in 1909 a teaching as well as an examining body. The medical degrees awarded are those of M.D., M.S., and M.B., B.S., the two latter being granted together as one degree. The medical degrees are granted to both internal and external students, the former being students of the constituent schools and colleges of the University.

**The Matriculation Examination.**—Students, before being admitted to the University, must either (1) have passed the Matriculation or the School Examination, or (2) have been exempted therefrom under Statute 110 of the University which recognises certain other examinations in lieu thereof. The examinations for matriculation take place three times in each year—in September, in January, and in June. Fee £2. If he withdraws before the last day of entry it will be returned to him. It he fails to present himself he will be allowed to enter for a subsequent Matriculation, within eight months, on payment of £1. If he retires after the commencement of the examination, or fails to pass it, the fee (£2 or £1), will not be returned on re-entry.

**Provincial Examinations for Matriculation.**—These are appointed by the Senate upon the application of any city, institution, or college desiring to be named as a local centre, and are carried on simultaneously with those held at the place of examination. They give notice upon their forms of entry to the Principal of the University, who will then make all necessary arrangements.

**Faculty of Medicine.**—The Faculty of Medicine grants the joint degrees of M.B., B.S. (Bachelors of Medicine and Surgery), and the higher degrees of M.D. (Doctor of Medicine) and M.S. (Mansfield Surgery). The curriculum for the medical degrees covers five and a half years, except in the case of students who have passed the Preliminary Scientific Examinations or the First Examination for Medical Degrees, before July, 1910, and the examinations respectively known as the Preliminary Scientific, the Intermediate, and the Final Examination in Medicine are now respectively entitled the First, Second, and Third Examinations for Medical Degrees.

The First Examination for Medical Degrees (inorganic Chemistry, Physics, and General Biology) takes place twice in each year, commencing on the Monday 4th of December and on the second Monday in January. The fee is £2 5s. for each subject.

The Second Examination for Medical Degrees (Part I): Organic Chemistry.—This examination takes place twice in each year. No candidate will be admitted to this examination within six months of having passed the First Examination. The examination consists of practical and mental examination. It consists of a paper and practical work, and may include oral questions in Organic Chemistry, which is "to be treated in an elementary manner, and with special regard to its applications in physiology, pharmacology, and pathology." The examination for Medical Degrees (Part II.) takes place twice in every year, commencing in the first Monday in March, and on the first Monday in July. The subjects of examination are Human Anatomy and Embryology, Physiology, and Pharmacology, including Pharmacy and Materia Medica. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees. The fee for each entry to the whole examination is £8. For re-examination in one subject it is £4.

**M.B., B.S. Examination.**—The M.B., B.S. examination takes place twice in each year, commencing on the second Monday in October and on the first Monday in May. Candidates will be examined in Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, Midwifery, and Diseases of Women. The subject of examination will be two groups, namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Midwifery, and Diseases of Women. These groups may be taken either separately or together. The fee is £5 10s. for entry to the whole examination, or £2 10s. each for examination or re-examination in either group. There will be no separate examination held for Honours, but the list of candidates who have passed will be published in two parts, namely, an Honours list and a Final Examination list.

**Doctor of Medicine.**—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates must have taken the M.B., B.S. degrees not less than two years previously, but for those who have taken the M.B., B.S. degrees with honours, or have done certain original work, this period of delay may be reduced to one year. Candidates who have obtained their M.B. degrees after 1st January, 1914, will not be allowed to hold the degree of B.S. before seeking the doctorate. They may present themselves for examination in one of the following branches, namely: (1) Medicine; (2) Pathology; (3) Mental Diseases; (4) Midwifery; (5) Diseases of Women; (6) State Medicine; and (7) Tropical Medicine. Any candidate for the degree of M.D. may transmit to the Registrar, not less than two months before the commencement of the examination, a thesis or published work embodying the result of his own independent research in the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners, the candidate may be exempted from the written examination in that subject. The fee is £20, and for re-examination £10.

**Matter in Surgery.**—The examination takes place twice in each year, and commences on the first Mondays in December and July. Candidates must produce certificates of having taken the degree of M.B., B.S. not less than two years previously (with certain exceptions, as in the examination for the M.D.) and of having subsequently held for at least six months a resident or non-resident Surgical Hospital appointment. The fee is £20, and for re-examination £10.

Full details can be obtained free on application to the Academic Registrar, University of London, South Kensington, S.W. Students should apply direct to the University for details in cases of special examination arrangements. University Entrance Exhibitions—University College.

**FACULTY OF MEDICAL SCIENCES.**—The Faculty of Medical Sciences comprises Physics, Chemistry, Botany and Zoology, also the Departments of Anatomy, Physiology, and Pharmacology (the latter of the Royal College of Physicians), and the Departments of Hygiene and Public Health, and of Pathological Chemistry (Post-graduate Study). Full Preliminary and Intermediate Courses of study are provided for students desiring to commence a course of study leading to the University of London and as well as for students seeking the qualifications of other Universities and licensing bodies. University and King's Colleges have been constituted University Centres for the teaching of degree courses in Medical Sciences. A student can enter the College directly, and at the end of the first and second courses select the Medical School and Hospital.
Chemistry; the Schäfer Prize in Physiology, value £50, for proficiency in Physiology; the Sharpie Physiological Scholarship, value £150, for Research in Physiology.

**Competition Fees.—**Course for the first Medical Examination, 26 guineas; course for the second Medical Examination, 21 guineas; course for the Final Examination of the Conjoint Board, 48 guineas.

The London Medical Schools recognised by the University with the title of "University of London," are:—University College, King's College, St. Bartholomew's Hospital Medical School, St. Thomas's Hospital Medical School, Westminster Hospital Medical School, Guy's Hospital Medical School, London Hospital Medical School, Charing Cross Hospital Medical School, St. Mary's Hospital Medical School, Royal Army Medical College, London School of Tropical Medicine, School of Medicine for Women, and the Lister Institute of Preventive Medicine.

**University of London—King's College, London, Strand.—**In the medical division of the Faculty of Science students are prepared for their first examination (Chemistry, Physics, Biology), and for their second examination (Anatomy, Physiology, and Pharmacology), by the University Professors attached to King's College, London, and their assistants. At present four medical schools, viz., those attached to King's College Hospital, Westminster Hospital, George's Hospital, and Charing Cross Hospital, the teaching in which is restricted to the subjects of the final examinations, send their students to King's College for the purpose of tuition in the above-mentioned preliminary and intermediate studies. Numerous Scholarships and Prizes are offered.

**Department of Public Health and Bacteriology.**—This department of King's College is served on in large laboratories in the Charing Cross Hospital Medical School, Whitechapel Road.

Full particulars as to courses of study, laboratory accommodation, hours, fees, etc., can be obtained on application to the Dean, Professor Halliburton, or the Secretary, Mr. Walter Smith, at the College.

Two diplomas, one Licence and six degrees in Medicine and hygiene are conferred—viz., the degrees of Bachelor of Medicine, Bachelor of Surgery, Master of Surgery, Doctor in Medicine, Bachelor of hygiene, and Doctor of hygiene. Diploma in public health and diploma in the speciality of the degree in Dental Surgery. These degrees, diplomas and licence are open to both men and women.

For the degree of Bachelor of Medicine (M.B.), there are four professional examinations. The subjects are: 1st year: elementary anatomy, biology, chemistry, and physics. For the second: Anatomy and physiology. For the third: Materia medica and pharmacy, pathology and elementary bacteriology, medical jurisprudence and public health; and for the fourth: Medicine, clinical medicine and medical therapeutics, surgery, and clinical surgery, pathology, internal diseases of women and children, and clinical gynaecology.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine and the Royal Infirmary, Newcastle-upon-Tyne. First and second year students (dating from registration) are not required to comply with the regulations regarding attendance on hospital practice. Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

For the degree of Bachelor of Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine at the University of Durham, and must have attended one course of lectures on operative surgery, and one course on regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and apparatus.

For the degree of Master of Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed the degree of Bachelor of Surgery, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor of Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquisition of the degree of Bachelor of Surgery in attendance on the practice of a recognised hospital or in the naval or military services, or in medical or surgical practice.

For the degree of Doctor of Medicine (M.D.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Matriculation Examination for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor of Medicine of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquisition of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the naval or military services, or in medical or surgical practice.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne. In the case of the M.B. (Essay) Examination, candidates must send in their essays six weeks before the date of the examination.

The New Royal Victoria Infirmary, containing 400 beds, was opened by the late King, in July, 1905. In the Dispensary the ordinary annuity of £3,000 is provided for the study of the various special subjects, in addition to the ordinary clinical work. Practical midwifery can be studied at the Newcastle Maternity Hospital. Opportunities for practical study are afforded by the Dispensary City of Diseases Hospital, Eye Infirmary, and at the Northumberland County Lunatic Asylum.

There are various appointments open to students, whilst the scholarships available are numerous and of considerable value.

**Fees.—**(a) A composition ticket for lectures at the college may be obtained—1. By payment of 80 guineas on entrance. 2. By payment of 50 guineas at the commencement of the first sessional year and 40 guineas at the commencement of the second sessional year. By three annual instalments of 40, 33, and 22 guineas, respectively, at the commencement of the sessional year. A Composition Ticket for the course of lectures and practical work of the first two years of the curriculum may be obtained by the payment of 42 guineas on entrance. (b) Single courses of lectures, five guineas. (c) Fees for attendance on hospital practice: For three months' medical and hospital practice, six guineas; for six months, ten guineas; one year, fifteen guineas; composition fee for one payment, thirty-five guineas; or by two instalments—viz., first year, twenty guineas; second year, eighteen guineas. In addition, two guineas yearly up to three years must be paid to the Committee of the Royal Infirmary. (d) Composition fee for entering the course for the Licence in Dental Surgery, 40 guineas. Composition fee for dental practical work at Newcastle Dental Hospital, 41 guineas.

A Licence in Dental Surgery has been instituted. Before proceeding to the First Examination, each candidate must furnish evidence, (1) of having attained the age of 21 years, (2) of having undergone a three-years' pupillage in mechanical dentistry with a registered dentist, and (3) of having been engaged in pro-
fessional study for at least four years subsequent to registration as a dental student. He must also sign such declaration as the University may binding himself not to advertise for professional purposes. Examinations are held concurrently with the medical examinations, and the fees payable by candidates amount to £1.5.

The Senate of the University has decided to grant a Diploma in Psychiatry, full particulars of which may be obtained from the College Calendar. Further particulars will be given on application to Prof. H. D. Fray, Secretary of the University of Durham College of Medicine, Newcastle-on-Tyne.

UNIVERSITY OF MANCHESTER.

Candidates for degrees in medicine and surgery (M.B., Ch.B., M.D., Ch.M.) must attend classes in the University during at least two years, and for three years must pursue a course of medical study at any college on professional course. They are required to have passed the Matriculation Examination, or other examination as may from time to time be recognised for this purpose by the University. The Matriculation Examination is held in July and in September before admission to the Degrees of Bachelor of Medicine and Surgery candidates are required to send in the usual certificate of age and study as at the other Universities. All candidates for these Degrees must have been present at the University in attendance upon the classes of the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees.

Degrees of Bachelor of Medicine and Bachelor of Surgery. — The candidate must have passed either the Matriculation Examination of the University or one of the following examinations, which will be accepted in lieu thereof for the present:—(a) The previous examination of the University of Cambridge; (b) Responses of the University of Oxford; (c) The matriculation examination of any recognised University; (d) The leaving certificate (higher) of the Oxford and Cambridge Boards; (e) The Oxford or Cambridge senior local examination.

Matriculation Examinations are held in July and September each year.

Degrees of Doctor of Medicine and Master of Surgery. — At the end of one year from the date of having passed the Final M.B., Ch.B. Examination, the candidate will be eligible to present himself for the examination for the Degree of Master of Surgery or both, the regulations for which may be had upon application to the Dean. The University also grants a Degree and a Diploma in Public Health, and provides adequate instructions for the same.

The Compendium of Fees for University Courses for Degrees of M.B., Ch.B. is £85; the Composition Fee for Clinical Instruction at the General and Queen’s Hospitals is £42; total cost for the full M.B., Ch.B. Curriculum including Examination Fees is £152 28 6d. School of Dentistry. — The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.), and a Diploma in Dental Surgery (L.D.S.). The whole of the instruction for which may be taken out in the University, with which is associated the Birmingham Dental Hospital. The instruction of Dental Students is carried out under the direction of the University Dental Clinical Board. The fees for L.D.S. Diploma courses are as follows: — Composition Fee (University Courses), £50; Clinical Fees for Dental and General Hospital instruction, £3 10s. total cost for L.D.S. including Examination Fees, £14 15s.6d.*

The total cost for Degree of B.D.S. and Diploma of L.D.S. is £149 1s.

THE GENERAL AND QUEEN’S HOSPITALS. — The practical studies of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the University Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 500 beds. 8,000 in-

* Does not include fee for Mechanical Pulpage, which is 5s. 10d.
ENGLAND—EDUCATION.

SEPT. 9, 1914.

The University also grants a Diploma in Dental Surgery (L.D.S.) and Degrees in Dental Surgery (B.D.S. and M.D.S.). The courses of systematic instruction are given in the University buildings, five minutes walk from the Dental Hospital.

Communications should be addressed to the Dean, Professor B. M. A., M.A., M.D., C.M. the University, Liverpool.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

The Diploma of Tropical Medicine, University of Liverpool.—The school is affiliated with the University of Liverpool and the Royal Southern Hospital, Liverpool, and the Royal Infirmary, Liverpool. The instruction given occupies eleven hours a day for five days a week during thirteen weeks. Each Course consists of (1) a systematic series of lectures on tropical medicine and sanitation delivered by the Professor of Tropical Medicine at the University; (2) of additional lectures on special African and other diseases delivered at the University; (3) of systematic lectures and demonstrations on tropical pathology, parasitology and bacteriology by the Walter Myers Professor, at the University; (4) of similar instruction on medical entomology by the Professor of Entomology at the University; (5) of clinical lectures and demonstrations delivered at the Royal Southern Hospital, Liverpool, under the charge of the Tropical Ward, Professor of Tropical Medicine, and the Walter Myers Professor; and of lectures or demonstrations by assistant teachers.

In December and April an examination is held by the University, and Fellowships of £100 a year are open to students of the school, amongst others. Accommodation for Research work is to be had, both at the University laboratory of the school, and at its Research Laboratories at Runcorn (sixteen miles distant from Liverpool).

Since it was instituted 15 years ago the school has employed 45 different investigators paid out of its funds, and has despatched to the tropics 33 scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in twenty-one special memoirs with many plates and figures, besides text books and numerous articles in the scientific press. From the beginning of 1907, however, the Memoirs have been succeeded by the Annals of Tropical Medicine and to be given to the Dean of the Faculty, with the exception of two, the Honorary Committee, and open to outside contributors, (Apply to the Secretary, 28, Exchange Buildings, Liverpool).

The Mary Kingsley Medal is awarded by the School for distinguished work in connection with tropical medicine, and has been given to Colonel Erace, Professor Koch, Dr. Laveran, Sir Patrick Manson, Lord Lister, Professor Looss, Professor Danielswusky, Dr. Charles Finlay, Mr. W. M. Haffkeine, Professor Goigl, Colonel Gorgas, Professor Theobald Smith, and H. A. Lister, and others.

UNIVERSITY OF BRISTOL.

The University grants the conjoint degrees in the Faculty of Medicine of M.B., Ch.B., the degree of M.D., Ch.M., B.D.S., and M.D.S.; also diplomas in Dental Health (D.P.H.) and in Dental Surgery (L.D.S.).

The conjoint Degrees of M.R.C., Ch.B.—The curriculum occupies five years and a half. The University
lectures and laboratory courses are attended in the large and well equipped new wing of the University. Hospital practice and Clinical instruction are provided in the affiliated hospitals, which together afford upwards of six hundred beds and a very large external medical department. Three years at least must be spent in the University, and two of them subsequently to passing the second examination.

Mechanical Dentistry may be studied in the new and well equipped University Laboratory under the supervision of a skilled mechanic. In this laboratory the mechanics of the mechanical work for the Royal Infirmary and the Bristol General Hospital is done by the pupils. Lectures and ordinary laboratory work are attended in the University, the Metallurgical laboratory is in the Chemical department, and has been specially fitted for the purpose.

Diploma in Dental Surgery, L.D.S.—The curricular occupies four years, and runs on very similar lines to that for the B.D.S. It is, however, necessary to pass the matriculation examination, and some subjects required for the degree are omitted. Candidates for either the B.D.S. or L.D.S. must be registered Dental students.

Diploma in Public Health.—The necessary laboratory work is done in the University in the Chemical and Pathological departments. The remainder of the curriculum is taken under the Medical Officers of the various local authorities, and the Assistant Medical Officer of the Port of Bristol (Demonstrator in Public Health).

Three courses are primarily designed for the University degrees and diploma, namely equal attention is paid and equal facilities are offered to students who enter for the degrees of other Universities, such as the University of London, and for the Diplomas of the various examination books. Women are admitted to all degrees and diplomas, and to the courses of study necessary for them. The University Hall of Residence is situated at Clifton, within a short distance of the University. Particulars of residence may be obtained from Miss M. C. Staveley, M.A., at the University.

Inclusive Fees.—For the M.B., Ch.B. curriculum, 150 guineas; for the B.D.S. curriculum (including mechanical practice), 150 guineas; for the B.D.S. curriculum (excluding mechanical practice), 115 guineas; for the L.D.S. curriculum (including mechanical practice), 168 guineas; for the L.D.S. curriculum (excluding mechanical practice), 115 guineas; for the D.P.H., 150 guineas. Arrangements can be made for paying these fees by instalments.

Appointments (Undergraduate).—Clinical Clerkships, Dresserships, etc., can be obtained at the Royal Infirmary and the Bristol General Hospital. In these institutions the Dressers reside in rotation free of charge.

Appointments (Post-Graduate).—At the Bristol Royal Infirmary: Two House Surgeons, £100 each per annum; two House Physicians, £100; Resident Obstetric and Ophthalmic House Surgeon, £150; Throat, Nose, and Ear House Surgeon, £75; Casualty Officers, £75; Demonstrator of Surgery, £100 per annum. Casualty Officers are appointed for twelve months, except that of Casualty Officer, which is for six months. From the resident officers a Senior Resident Office is appointed at an additional salary of £30. At the Hospital General Hospital: Senior House Surgeon, £150 per annum; Casualty House Surgeon, £100 per annum if another resident appointment has previously held; two House Physicians, £50; House Surgeons but clinical practice only, £100 per annum. All these appointments are for six months, except that of Dental House Surgeon, which is for two years.

The Winter Session opens on September 30th.

UNIVERSITY OF LEEDS.

The school of medicine attached to this University was founded in 1831 as the Leeds Medical School. The building, erected on a site contiguous to the infirmary, contains one of the finest dissecting-rooms in the United Kingdom, extensive laboratories for physiology and pathology with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a medical library, and appreciable facilities for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the Leeds General Infirmary in the United Kingdom, having 540 beds, with a staff of physicians and surgeons of considerable eminence. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, while also are clinical demonstrations in various wards, and an extern maternity charity is attached, at which the necessary attendance at labourers can be taken. Besides the infirmary there is a large hospital for infectious diseases, a hospital for women and children, and a maternity hospital, all of which are open to students of the school.

Scholarships, Prizes, etc.—(1) An entrance scholarship of £150 is offered annually by the University. Degrees and Diploma in Dental Surgery are obtainable at this University, being Bachelor of Dental Surgery (B.Ch.D.), and Master of Dental Surgery (M.Ch.D.). Candidates for the Bachelor of Dental Surgery are required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University in the Schools of Dentistry and Pharmacy, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the Regulations of the University. No candidate shall be admitted to the degree who has not spent the age of twenty-one years on the day of graduation.

Candidates for the diploma in Dental Surgery are required to present certificates showing that they have attained the age of twenty-one years, that they have attended courses of instruction approved by the University, extending over not less than four years, two of which must be spent in the University, and that they have completed a pupilage of three years, two of such years at least having been taken before the First Professional examination. Candidates must be enrolled in one of the following subjects of the following examinations: A preliminary examination in Anatomy; A preliminary examination in Pathology; A preliminary examination in Physiology; A preliminary examination in Surgery; A preliminary examination in Obstetrics; A preliminary examination in Ophthalmology; A preliminary examination in Dermatology; A preliminary examination in Orthopaedics; A preliminary examination in Clinical Medicine; A preliminary examination in Dental Surgery; A preliminary examination in Dental Practice; A preliminary examination in Dental Anatomy; A preliminary examination in Dental Physiology; A preliminary examination in Dental Pathology; A preliminary examination in Dental Hygiene; A preliminary examination in Dental Surgery; A preliminary examination in Dental Practice; A preliminary examination in Dental Anatomy; A preliminary examination in Dental Physiology; A preliminary examination in Dental Pathology; A preliminary examination in Dental Hygiene.

A Diploma in Public Health (D.P.H.) is granted after examination under the usual regulations, also a Diploma in Psychological Medicine.

UNIVERSITY OF SHEFFIELD.

By the Charter granted in 1905, this University is permitted to grant degrees in medicine. All its courses and all its degrees are open, without restriction, to both sexes. The new buildings of the University, opened by the late Majesty King Edward VII, are attached to the west of the adjoining Weston Park. The medical department occupies the entire north wing of the University quadrangle, and is within easy
reach of the various hospitals, with which it is connected for clinical purposes.

The hospital services—The Royal Infirmary contains 350 beds, and the Royal Hospital 191 beds. The practices of the two institutions are amalgamated for the purpose of clinical instruction, giving a total of over 420 beds for the treatment of medical, surgical, and obstetrical cases. The last year over 30,000 patients passed through the wards of the two institutions, while those attending as out-patients numbered over 35,000. The Jessop Hospital for Diseases of Women contains 300 beds, with about 1600 out-patients per annum, and about 900 out-patient cases attended. Special courses on tetanus are held at the City Fever Hospital, and at the London Fever Hospital, the medical attendants being provided by the University.

MEDICAL IVAIL.

The University and its Colleges in England and Wales was established by the University of London, and is a well-ordered hospital service, and is situated within five minutes' walk of the University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunities thus afforded to pursue the earlier part of the medical curriculum near home, and are enabled to both men and women students over sixteen years of age. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the Universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent at least three years in study at Cardiff, and having passed the examinations in these years, a student may proceed to London or elsewhere and complete his qualifying course for a University degree of for a college diploma.

Students preparing for the first and second examinations of the Joint Board for England, or for the corresponding examinations of the Joint Board for Scotland, may compound for their classes by paying a single composition fee of £40, at the beginning of their first and second years respectively. Those preparing for the First and the Second Examinations for Medical Degrees of the University of London may compound for their three years' instruction at Cardiff by paying a single composition fee of £50, or by paying £20, £25, and £25 at the beginning of their first, second, and third years respectively.

In 1859 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for the diploma in Public Health and Hygiene of the University of Wales can attend complete courses of lectures and laboratory instruction in this department. These courses are also recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, by Victoria University, and by other examining boards.

In the case of medical students, attendance on the class of hygiene and public health, is conducted by the University of London and Cambridge, and by the Joint Examining Board of England.

Courses of lectures to midwives, adapted to the requirements of the Central Midwives Board, under the Midwives Acts, are commenced in October, June, and April. The lectures are suitable both for pupil midwives and practising midwives, as well as for nurses who desire to enter for the examination for certification under the Act.

SCHOLARSHIPS AND FREE STUDENTORIES.—The attention of students intending to matriculate is drawn to the entrance scholarships and Free Studentships which are offered at the close of competition in April, most of which may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar, or from the Dean of the Medical Faculty.

THE ENGLISH COLLEGES.

The medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Royal College of Physicians and Surgeons of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma (L.S.A.) in medicine, surgery, and midwifery.
CONJOINT EXAMINING BOARD IN ENGLAND.

Candidates for the above licences are required to complete five years of practical experience in medical schools and hospitals, after passing the preliminary examination, of which six months may be spent at an institution recognised by the Board, to comply with the following regulations and to pass the examination forthwith or at the end of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women a certificate of having received the subsequent instruction, not less than three months' instruction in the subject of the recognised teacher. A candidate who possesses a registrable qualification is admissible to re-examination without producing additional certificates.

REGULATIONS FOR COLONIAL, INDIAN, AND FOREIGN CANDIDATES, AND UNIVERSITY CANDIDATES.

Persons holding a Colonial, Indian, or a foreign qualification enabling them to practise medicine in the country of origin, and conferred after a course of study and examinations equivalent to those required by the Medical Council of the United Kingdom, are admitted to the second and third (final) examinations forthwith.

Members of a University in the United Kingdom and Graduates of Medicine of certain recognised Colonial or Foreign Universities are, under certain conditions, and subject to the regulations stated below, admissible two years after passing at the University in the subjects included in the first and second examinations of the Board.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEMBERS.—The membership of the College is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised University are admitted to a pass examination, but others must have passed the examinations required for the licence of the College. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors, Candidates under 40, unless they have obtained a degree in arts in a British University, are examined in Latin, and either Greek, French, or German. Candidates under 40 who have not obtained a degree in arts in a British University, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a licentiate £15 is deducted. In either case £60 has to be paid before examination.

ROYAL COLLEGE OF SURGONS OF ENGLAND.

MEMBERSHIP.—The candidates are now subject to the regulations of the Joint Board.

FELLOWSHIP.—The Fellowship of the College of Surgeons is granted after examination to persons above the age of 25 years, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the age of 25; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for fellowship examination, after the age of 25, who have passed the final examination of the Joint Board in England, and have been admitted members of the College before they can be admitted thereto, except in the case of graduates in medicine and surgery of recognised Universities who have not been so in England. The diploma of Fellow is granted to successful women candidates subject to the provisions of the Medical Act, 1858, and of the Bye-Laws of the College.

FEE.—For re-examination in medicine, £6 12s. For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III.—For re-examination in medicine and surgery, £4 12s.; in medicine and public health, £2 12s.; for examination in practical pharmacy (if taken at this examination), £2 2s. Part II.—For re-examination in surgery,
ENGLAND—EDUCATION.

Sect. 6, 1914.

The fee is £21. (The examination fees to the extent of £17 17s. 6d. count as part of the total fee.) Further information can be obtained on application to the Secretary of the Examining Board in England, Examination Hall, Queen Square, Bloomsbury, London, W.C.

SOCIETY OF APOTHECARIES OF LONDON.

PRIMARY EXAMINATION.—This examination consists of two parts: Part I.—Elementary biology, Chemistry, and Physics. This part contains such questions as are of a general nature, and an attempt is made to cover the subjects of the second year of a course of study in those universities which have a preliminary examination in chemistry and physics. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The final examination is held monthly, except the month of September, and is divided into Sections 1 and 2.

Section 1 consists of three parts:

Part I. includes: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes: (a) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (b) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (a) or (b) will not be re-examined therein.

Part III. includes: Midwifery, Gynecology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III., together or separately.

Section 1 of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of commencement of medical study.

Section 2.—This section consists of two parts:

Part I.—Clinical Surgery.

Part II.—Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the expiration of the fifth year.

Fees.—Primary examination, £5 5s.; final examination, £10 10s.; total fee, £21.

Further information, with particulars as to the course of study and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

The licence to act as a diplomate in Medicine, Surgery, and Midwifery, and to qualify the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

The gold medal is worth £50, and a silver medal, £25. A medal for the best paper in the preliminary examination is given for laboratory instruction for D.P.H., £15 per annum. For Primary F.R.C.S. Class, 10 guineas; for Final F.R.C.S. Class, 20 guineas. Full details will be supplied on application to the Dean.

CHAIRMANS CROSS HOSPITAL.—The School attached to this Hospital is situated in Central London, and contains new pathological and bacteriological laboratories, pharmacological, materia medica, and public health, laboratories, theatre. Clinical instruction is given in surgery, and obstetrics, and in the special departments, diseases of the skin, diseases of children, mental disorders, the throat, the eye, nose and ear, and in the orthopaedic, Röntgen and electrical departments.

The school arranges for a complete education in all departments, with special teachers for all preliminary and intermediate subjects.

By arrangement with the University of London, all students for the Primary and Intermediate portions of the course are eligible for any student to receive instruction at King's College Laboratories, situated within a few minutes' walk from the Hospital.

The entire teaching of the school is devoted to pathological, clinical and other subjects of final studies.

Appointments.—Ten house physicians and ten house surgeons are appointed annually. During the first six months of their appointment they act as house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £30 a year.

A second assistant anaesthetists are appointed, and receive salaries of £20 and £25 a year respectively. An external midwifery assistant receives a salary of £25 a year. Chief assistants and clinical assistants are also appointed in each of the Medical Surgical special departments.

SCHOOLS.—There are three Entrance scholarships in science, £75, £75, £150, tenable for one year, and an Entrance Scholarship in Arts, value £100, and the Jefferium exhibition, value £50; at the end of first year four junior scholarships of £50, £50, £25, £15, respectively; Treasurer's prize for practical anatomy; at end of second year Foster prize in practical anatomy; senior scholarship, value £50, for anatomy, physiology, and chemistry; Wix prize, Michens prize, for Senior Students, two Bracketen scholarships, £50, £15; |for medicine and surgery, £25; for report of cases; the Kirkes gold medal for clinical medicine, with scholarship of £50. Shuter scholarship of £50; Skyner prize of £15; Sir G. Burrows' prize of £10; Matthews Duncan prize, medal and scholarship of £50. The dentist Holdem Research Scholarship in Surgery, value £105; Lawrence Research scholarship and gold medal, value £115 for pathology.

Composition Fees.—(5) For students commencing their medical studies, one sum on entrance, 15 guineas; or by four instalments of 45 guineas each. (2) For students who have passed an examination in preliminary science, in one sum on entrance, 145 guineas; or by instalments. (5) For students who have finished two years of study but have not passed an examination completing their anatomical and physiological studies; if paid in one sum on entrance, 110 guineas; or by annual instalments. (4) For students who have completed three years of medical study but have not passed an examination completing their anatomical and physiological studies, in one sum, 80 guineas; or by annual instalments. The London School of Medicine and Surgery—20 guineas; for laboratory instruction for D.P.H., 15 guineas. For Primary F.R.C.S. Class, 10 guineas, for Final F.R.C.S. Class, 20 guineas. Further details will be supplied on application to the Dean.

The Schools in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with the schools and medical schools.

LONDON SCHOOLS.

The Schools of Medicine in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with the schools and medical schools.

St. Bartholomew's Hospital.—This hospital has 750 beds, and for many years past the school attached has been one of the number of medical schools in London. Laboratories have been specially equipped for the study of pathology, bacteriology, public health, chemistry, biology, physics, and chemical pathology, and two additional operation theatres, new casualty and out-patients' departments, eight special departments, quarters for the junior staff, a dining-hall and a common-room for students that have recently been built. Collegiate residence is permissible, subject to the ordinary rules.
**Payment**—The fees for the five years' curriculum may be paid either by composition fee, in one sum, on joining, and payment of the annual fees for the first year, or by a composition fee of £100 for each year, subject to the condition that the candidate shall obtain at the end of each year an average of 90 per cent.

**Appointments.**—Eight house surgeons, eight house physicians, sixteen out-patient officers, sixteen assis-
tant house surgeons. Twenty-six private residents, two ophthalmic house surgeons, twenty-one anaesthetists, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments to the various departments of the practice being systematically employed for instruction.

**Scholarships.**—Open scholarships of £120, £100 and £50 in biology, chemistry and physics, classics, mathematics and modern languages, and two open scholarships of £150 and £75 in two of the following subjects—Anatomy, physiology, pharmacology, general pathology and organic chemistry. The following are the scholarships, prizes and medals open to students at the hospital: Junior prizes for general proficiency, £20; £15; £10; Hilton prize for King's; £10; Michael Harvey prize for anatomy, £5; Sands Cox scholarship for physiology, £15; Woolridge prize for physiology, £10; Beaney prize in pharmacology, £34; Golding-Bird prize in bacteriology, gold medal and £100; Treasurer's gold medal in clinical medicine; Treasurer's gold medal for service in teaching; Beaney studentship in materia medica (tenable for 3 years), annually £100; Gull scholarship in pathology (tenable for 3 or 5 years), annually £150. The King's College Hospital Medical School has also a series of scholarships of the value of £100, triennially; Oldham Prize in Ophthalmology, £30 annually.

**Fees.**—A new system for payment of composition fees has been instituted at this school. Particulars may be obtained on application to the Dean, Guy's Hospital, London Bridge, S.E.

**Universities of London—King's College, London, Strand.**—In the medical division of the Faculty of Science students are prepared for their first examination (Chemistry, Physics, Biology, and, for their second examination (Anatomy, Physiology, and Pharmacology) by the University Professors attached to King's College, London, and their assistants. At present four medical schools, viz., those attached to King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital, the teaching in which is restricted to the subjects of the final examinations, send their students to King's College for the purpose of tuition in the above-mentioned course of study, and pay for it.

Numerous Scholarships and Prizes are offered.

**Department of Public Health and Bacteriology.**—This department of King's College is carried on in large laboratories, part of which is the King's College Hospital Medical School Building, Chandos Street.

Full particulars as to courses of study, laboratory accommodation, hours, fees, etc., can be obtained on application to the Dean, Professor Watersin, or the Secretary, Mr. Walter Smith, at the College.
tutors, Sambrooke medical and surgical registrarships, tenable for two years each, £70 per annum. Residency in hospital appointments,—viz., casualty officer, senior and junior house physicians, physician, anæsthesist’s assistant and assistant house anæsthesists; house obstetrician; assistant clinical and dental laboratory assistant; and three anæsthesists.

F. R. C. S. Examinations.—Special classes are arranged for the final F. R. C. S. exam. Further particulars can be obtained post free from the Dean, Dr. H. Willoughby Lye, or the Secretary, Mr. Clifton Kelway, King’s College Medical School, Denmark Hill, S.E. 5.

Fees.—The fees payable by full students for the Course of Advanced Studies, whether for the University Degrees or for the Examinations of the Conjoint Examining Board, are: So guineas if paid in one sum; £25 guineas if paid in instalments, as follows: 10 guineas at entrance; first payment, 40 guineas on entering the hospital; 32 guineas at commencement of second year. These fees also include membership of the Hospital Clubs and Societies’ Union for three years. Completion fees have been arranged for the complete medical courses.

(i) University of London Course, including the Preliminary Scientific, Intermediate, and Final Course, Fee, £150 guineas.

(ii) Conjoint Examining Board Course, including the courses for the 1st, 2nd, and 3rd examinations, Fee, £150 guineas.

The London Hospital.—This hospital is the largest in Great Britain, containing, as it does, 922 beds. It has large wards and a large staff, for every special department in the domain of medicine; the scholarships and prizes are many and valuable.

Appointments.—The salaried appointments open to students are those of medical registrars three, surgical registrars two, junior anaesthetists two, out-patients, clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopedic, and electrical departments. There are also six resident house physicians and nine resident house surgeons, two accoucheurs, seven receiving-room officers, two emergency officers, and three pathological assistants. Also unpaid clinical assistants in the various special departments. In addition there are numerous house officers and clerks and dresserships in the various departments.

Scholarships and Prizes.—At Entrance: Price scholarships in science, £100; in anatomy and physiology, £52 10s.; entrance scholarship in science, £50; Epsom scholarship in science, £20; Buxton scholarships in arts, £31 10s. After Entrance: anatomy and physiology prize, £25; Lethby prizes, £25; prizes in clinical medicine, surgery and obstetrics, £20 each; Duckworth Nelson prize, £10; Hutchinson prize, £10; Sixth Medical Prize, £25; Anderson prizes, £50; dressers’ prizes, £50; practical anatomy prizes, £10; Douro Hoare prize, £25; Wynne Baxter prize, £50.

Special classes for the 1st and 2nd M.B., Lond., the 1st and final Fellowship, and other examinations are held. Those for the final and primary F. R. C. S. commence on September 2nd.

Fees for Full Course.—Entrance Fee 20 guineas; annual Fee 30 guineas.

Special entries can be made either for single courses of lectures or for hospital practice. The Students’ Hostel has recently been extended. Residential accommodation is obtainable at a very reasonable rate close by, or in the suburbs a few minutes’ distant by train.

A Dental School is attached to the Hospital and provides the Course of Instruction for the Dental Diploma examinations.

Full particulars can be obtained from the Dean, Professor William Wright, M.I., D.Sc., F.R.C.S.

St. Mary’s Hospital.—This Hospital is situated at

Fauldington, near the terminus of the Great Western Railway, contains 250 beds, of which 31, in the Clarence Wing, are devoted to treatment by Therapeutic Inoculation. An additional Operating Theatre has recently been opened in this wing. The Inoculation Department, instituted in 1906, has greatly expanded the scope and facilities of this wing.

The Department is under the personal supervision of Sir Almroth Wright, F.R.S.

In 1912 a new Casualty Department was opened, with increased accommodation.

The Athletic Ground is situated at Park Royal, Acton, within easy reach of the Medical School. This provides ample accommodation for the various athletic clubs, and possesses a good pavilion.

Appointments.—All clinical and surgical medical officers in the hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident medical officers to the inoculation wards are appointed in each year, and receive board and residence in the Hospital. Four casualty house surgeons, and two resident anaesthetists are appointed annually, the term of office being six months. They receive a salary at the rate of £100 per annum with board and residence.

Scholarships, &c.—One scholarship in natural science of the value of £100, open to any gentleman who has not completed a winter session of study at a medical school, and the scholarship shall be awarded to the student who attains the highest mark in the examination of the Unions, or the value of £150—under the same conditions. Two scholarships, each of 50 guineas, open to University Students. The scholarships will be awarded by examination on September 21st, 22nd, 23rd.

Fees.—The attendance of the full-time curricular studies of the hospital, practice and all lectures, demonstrations, and special tutorial classes, £140, paid in one sum on entering the school; or in instalments, £415. Payments may be made by annual fees, as an alternative to composition fees.

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 50 guineas in one sum, or 75 guineas in two annual instalments.

Complete Curriculum.—The Medical School provides complete instruction for the various medical degrees and diplomas, including courses of preliminary scientific and intermediate subjects, which are recognized by the University of London as approved courses for formal credit. Students may join in October, January, or April.

The Middlesex Hospital.—The Hospital and Medical School are centrally situated, and within a few minutes’ walk of the principal tube and railway lines of the Metropolis.

The Hospital contains 440 beds, including special wards for cancer cases, maternity and gynaecological cases, and for diseases of the skin and eye. The cancer wing (containing 66 beds) and special investigation laboratories offer unrivalled opportunities for the student or medical officer, both in the biological and pathological aspects. In the electro-therapeutical department students obtain instruction in the treatment of lupus and cancer by the X-ray method.

The Hospital and Medical School are fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health. The Bland Sutton Institute of Pathology, just completed, is under the immediate direction of the Professor. It contains a new lecture theatre, large laboratories for teaching purposes and smaller rooms fully equipped for the carrying out of research work. Special classes are held to prepare students for the intermediate examinations at the Universities, and for the intermediate and final examinations for the F.R.C.S. (England) Diploma.

There is a residential college in the hospital for a limited number of students.

Hospital Appointments.—All appointments are
made without fee of any kind, and the following appointments are made annually:—Six house physicians, eight house surgeons, two obstetric and gynecological surgeons, two casualty surgeons, and two resident officers to the special departments. Non-resident clinical assistants are appointed to assist in the various out-patient and casualty departments.

Scholarships, Prizes, etc.—Three entrance scholarships, value £100, £50, and £25, and a University Scholarship, value £25 (for Oxford and Cambridge students), are awarded annually in September. A first-class pass at University entrance at the University of Epsom College, is awarded annually on the nomination of the headmaster. There are also two Broderip Scholarships, value £50 and £25 respectively; the John Murray Medal and Scholarship, value £25 (awarded every third year); the Freeman Scholarship, value £50; the hetley clinical prize, value £25; the Leopold Hudson prize, value 11 guineas; and the second year's exhibition, value 10 guineas. There are also numerous class prize examinations. In connection with the cancer investigation department, the following scholarships are awarded:—Richard Bucknill Scholarship, value £100; Salters’ Company Cancer Research Scholarship, value £100; and a Cancer Research Scholarship, value £50.

Fees.—The composition fee for the curriculum for the diplomas is £100. The fee for the introduction to the Royal College of Physic is £50; the fee for the degree of the University of London, 145 guineas; for those who have passed the first examination for the degree in the arts of those who have completed their anatomical and physiological studies, 70 guineas. The fee for dental students is 54 guineas. The fees may be paid by instalments.

The Amalgamated Students’ Club includes:—The Medical Section common room society, the Cricket and Football Clubs, etc. The Athletic Ground, which is eight acres in extent, is situated within easy access of the hospital—at Park Royal. A subscription to the Club is payable by all General and Dental Students.

The Winter Session 1914-15 opens on October 1st at 3 p.m. The Introductory Address will be delivered by Mr. Herbert Bond, M.B., D.S.O. after which the prizes will be presented by His Serene Highness Prince Alexander of Teck, G.C.B., G.C.V.O., D.S.O.

St. Thomas’ Hospital.—This Hospital, with medical school attached, is situated on the southern Embankment of the Thames, facing the Houses of Parliament. The medical college was constituted in 1824.

The school buildings, which are separated from the hospital by a quadrangle, comprise numerous theatres, laboratories, and class rooms, which are well adapted for the modern teaching of large bodies of students in all subjects of the medical curriculum. There is a large library and reading-room, and a very complete museum and gymnasium.

Appointments are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £150 and lodging. Four hospital registrars, two at an annual salary of £100 each, and two at £50 each, are appointed yearly. The tenure of these offices may be renewed. Ten house surgeons, exceeding two years, two resident house physicians, four casualty officers, two resident obstetric house physicians, and two ophthalmic house surgeons are appointed each month, eight out-patient officers, and clinical assistants in the special departments, two resident assistants are appointed annually at a salary of £200 per annum.

Scholarships, Prizes, etc.—Five entrance scholarships are offered for competition in July and September—viz., one of £150 and one of £60 in chemistry, physics, and biology at the commencement of the second year; one of £50 open to University students who have passed in anatomy and physiology, for a medical degree in any of the Universities of the United Kingdom, and who have not entered as students in any London Medical school, and two scholarships in arts giving free tuition for the first year of curriculum. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student. There is a Fund established by the Salters’ Company for research in pharmacology, and the Louis Jenner research scholarship, £60, for pathological research.

Special courses of instruction for the First Professional Examinations, and for the Preliminary and Intermediate Medical, for the Oxford and Cambridge examinations, and for the Primary and Final F.R.C.S. are held throughout the year.

The prospects of the school may be obtained on application to Mr. G. Q. Roberts, Secretary of the Medical School.

 Fees.—A system for payment of composition fees is in operation. Full details may be obtained of the Secretary.

University of London, University College.—Faculties of Medical Sciences.—The Faculty of Medical Sciences comprises Physics, Chemistry, Botany and Zoology, also the Departments of Anatomy, Physiology, and Pharmacology (the Intermediate Medical Sciences) and the Departments of Hygiene and Public Health, and of Pathological Chemistry (post-graduate study). Full Preliminary and Intermediate Courses of study are provided for students desirous of obtaining the medical degrees and diplomas of the University, as well as for the students seeking the qualifications of other Universities and licensing bodies. University and King’s Colleges have been constituted University Centres for the teaching of the Medical Sciences. A student can transfer from one Centre to another. At the end of the first and second courses select the Medical School and Hospital.

Scholarships and Exhibitions.—Five annual University Entrance Exhibitions of £100 a year, six similar scholarships of £50 a year each in science subjects are annually awarded, and three Andrews Entrance Scholarships. The Bucknill Scholarship of 135 guineas and two Exhibitions of 55 guineas are awarded of open competitions each year, held in July. The Cliff Memorial Prize, value £15, is awarded for proficiency in Anatomy, Physiology, and Chemistry; the Schlier Prize in Physiology, value £18, for proficiency in Physiology; the Sharpie Physiological Scholarship, value about £150, for Research in Physiology.

Composition Fees.—Course for the first Medical Examination, 26 guineas; course for the second Medical Examination, 28 guineas; course for the first Examination of the Conjoint Board, 21 guineas; course for the second Examination of the Conjoint Board, 28 guineas.

The London Medical Schools recognised by the University of London in 1914-15 are—University College, King’s College, St. Bartholomew’s Hospital Medical School, St. Thomas’ Hospital Medical School, Westminster Hospital Medical School, Guy’s Hospital Medical School, Middlesex Hospital Medical School, Charing Cross Hospital Medical School, St. Mary’s Hospital Medical School, Royal Army Medical College, London School of Tropical Medicine, School of Medicine for Women, and the Lister Institute of Preventive Medicine.

University College Hospital and Medical School.—Entrance.—A student may enter the school as soon as he has passed the University of London Matriculation Examination, and is competent to take qualifying preliminary examinations. In this case he will pursue his preliminary and intermediate studies at University College, and his final medical studies at University College Hospital Medical School. The student who has completed his preliminary and intermediate medical studies elsewhere, may enter the University College Hospital Medical School for his final medical studies only. Qualitative medical men and others who can produce evidence of sufficient qualifications may be admitted as students in various departments of the University for purposes of research, or to hospital practice for certain definite periods.

University College Hospital now accommodates 205 in-patients, and possesses extensive out-patient and special departments.

Thirty-eight clinical appointments, eighteen of
which are resident, are filled by competition during the year, and are open to students at the hospital without extra fee.

The new medical school provides for lectures, demonstrations and practical work in all the final subjects of the medical curriculum. There are three lecture demonstration theatres for the teaching of morbid anatomy, bacteriology, and chemical pathology; also rooms equipped for the teaching of operative surgery and surgical anatomy, and two large lecture theatres.

The Medical Society, founded in 1826 for promoting the study of medical and surgical sciences among students for social intercourse, has rooms set apart for reading and conversation, and there is a large museum and squash rackets court with baths attached in the school buildings.

**Scholarships, etc.—** Entrance scholarship of £15 guineas, and two of 80 guineas each, the subjects being anatomy and physiology; the Graham scholarship in pathology, £200 per annum; the Atkinson-Morley surgical scholarship of £15 a year, tenable for three years; the Atkinson scholarship, value £15, tenable for two years; the Magrath clinical scholarship of £100 for reports on post-mortem examinations; the Regius scholarship for prosector in pathological anatomy, value £15; Euston prize, operating case, value £100, awarded for practical surgery; Fellowes gold and silver medals, the Edinburgh gold medal, Alexander Bruce gold medal, Tuke medal, £100, and other medals, as well as certificates of honour, are awarded after competitive examinations in particular branches of study.

**Composition Fees.**—The Preliminary Course at University College, 20 guineas; Intermediate Course at University College, 58 guineas; final M.B. Course at University College, 150 guineas; Medical School, 80 guineas if paid in one sum or 82 guineas paid in two instalments of 50 and 32 guineas.

**Westminster Hospital.**—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the Metropolis. It contains 295 beds for general cases, and all the special departments. The school buildings are close by, which afford accommodation for 150 students. The class rooms, museum, laboratories, and lecture theatre are excellent samples of modern erection, attending ample scope for study.

**Appointments.**—Medical and surgical registrars, each £300 per annum; two house physicians, three house surgeons, one physitian, one assistant house surgeon, and a resident obstetric assistant. These officers, except the two first named, are all bound free of expense. Qualified students are assisted to be clinical assistants in the various departments.

**Scholarships, etc.**—(a) Winter Session.—The Guthrie scholarship, £50; subjects, Latin, mathematics, English, and either Greek, French or German. Two University scholarships, £50 each; subjects, anatomy and physiology. Natural science scholarship, £50; subjects, same as for Preliminary Science of University of London. Natural science scholarship, £50; subjects, chemistry and physics. (b) Summer Session.—Two University scholarships as for Winter Session. Special prizes to be awarded for unqualified men. Chadwick prize for Obstetric Medicine and Surgery, 20 guineas, for students of any year not exceeding fifth. Bird medal and prize, in Obstetric Medicine. £14, for students who have completed fourth with the highest marks in four, and are in the first half of the class. Sturges prize in Clinical Medicine, about £50, clinical cases at the prize side; £10, Abrahams prize in Clinical Pathology, 5 guineas. And class prizes in the various subjects.

**Fees.**—(a) The Annual Composition Fee is 25 guineas. This includes the subscriptions for membership of the Club's Library. (b) For lectures, £2 10s. per course for single courses the fees may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments of £25 10s. each.

**London (Royal Free Hospital) School of Medicine.**

**Cine for Women.**—The school is situated in Hunter Street, and the Royal Free Hospital is in Gray's Inn Road, close by. Students are prepared for the London University examinations and for the examinations of other Universities. A course of study is also arranged for the work required by the Royal Colleges of England, the Conjoint Colleges of Scotland and the Society of Apothecaries of London. The Royal Free Hospital contains 105 beds available for clinical study; and in addition there is a large out-patient and casualty department and a maternity department with 11 beds. In addition to the ordinary systematic lectures at the school, clinical lectures are given at the hospital in Medicine, Surgery, Obstetrics, Ophthalmology, Otolaryngology, Pathology, Bacteriology, and Laryngology. Students hold clerkships and dresser- ships in each department.

**Appointments.**—House physicians, house surgeons, and a senior and junior resident obstetric assistant are appointed yearly. There are also non-resident appointments, including the anaesthetists and assistant obstetricians, assistant and clinical pathologists, medical and surgical registrars, curator of museum and clinical assistants.

**Fees.**—The fee for the University course and the course for the Royal Colleges of England is £150 in one sum, or £170 if paid in five instalments. The fee for the course for the Scotch Colleges or Society of Apothecaries of London is £140 in one sum, or £150 in four annual instalments. Particulars as to scholarships, etc., can be obtained from the Secretary and Warden, Miss L. M. Brooks, 1, Greek Street, Soho.

**London School of Tropical Medicine.**—The next session of the School commences on the 1st of October. The past year has been one of the most successful on record, and over 60 students attended the session ending in July. The course is arranged to equip men for the Cambridge Diploma in Tropical Medicine and Hygiene, the London Diploma in Diseases and Hygiene of the Tropics, as well as for the London University M.D. Special facilities are now afforded for advanced study, as in entomology, helminthology, protozoology and tropical sanitation and hygiene. Resident accommodation for students is available in the Hostel. The Wandsworth Scholarship of £150 and the Hon. Edward John Stanley Memorial Scholarship of £30 are awarded annually. The School provides three sessions each year.

**INTRA-ACADEMIC INSTITUTIONS.**

**The Royal Dental Hospital.**—The teaching and hospital offices (situated in the Institute Buildings in Leicester Square) are recognised by the various examining bodies. The new hospital and school, which was opened seven years ago, is complete in every detail with modern appliances. The clinic of the hospital is unrivalled, no fewer than 82 operations being performed in one year. The following scholarships and prizes are open to all full-term students:—Entrance scholarships, of the value of £50 and £52, both awarded in October. Subjects: Chemistry and Physics, Saunders scholarship, of the value of £50, awarded to the student obtaining the highest aggregate number of marks in a special examination of the subjects of the final examination in the B.D.S. course of the Royal School of Dental Surgery, of the value of £25, the subjects being Dental Mechanics and Metallurgy. There is also an Entrance Scholarship of £25 open to those who have studied "Dental Mechanics" under the tuition of Mr. G. R. Underwood. Research Scholarship, of the value of £50, awarded once in three years; the Alfred Woodhouse Scholarship of £50, and the Robert Woodhouse Prize of the value of £10, for practical dental students. Classes are held with various lecturers. Provision is made for teaching Dental Mechanics, as required by the Royal College of Surgeons, the pupils being under the guidance of the staff of dental surgeons assisted by specially nominated assistants. The School contains an excellent library and a well-arranged museum.

**Fees.**—For the two years' hospital practice and lectures as required by the Royal College of Surgeons.
of England, the fee is £5 5s. in one instalment, or £5 13s. in two yearly instalments. The fee for the complete curriculum—namely, two years' instruction in Dental Mechanics and two years' hospital practice and lectures, is £5 10s. per annum if paid in three instalments of 50 guineas each. It is paid in four instalments, viz., first year, 50 guineas, second year 50 guineas, third year 25 guineas, fourth year 25 guineas. For one year's medical lectures only, the fee is £20, or 50 guineas.

For one year's hospital practice, £21. For the courses in Chemistry and Physics for the Preliminary Science Examination, 10s. The necessary course of two years at a general hospital can be taken simultaneously with that at the Dental School. Any particulars can be obtained on application to the Dean.

NATIONAL DENTAL HOSPITAL (The Dental Department of University College Hospital).—Students are entered as students of University College Hospital, and, as such, attend the classes of chemistry, physics, anatomy and physiology at University College, a few minutes' walk from the Dental Department in Great Portland Street, where excellent teaching facilities and hospital practice are obtainable, special demonstrations being given in the Dental Hospital. There are also mechanical laboratory, bacteriological laboratory, X-Rays Department, museum, students' common room, a metallurgical laboratory, extraction and stopping rooms, lecture hall, regulations room, etc., all lighted by gas and gas and doubtless after the most approved requirements; in fact, this institution may be pronounced a model dental department of a general hospital and school. The winter session commences at the same time as at the medical school, on the first of October. The medical school holds special classes before each college examination. The prizes include two entrance exhibitions, value £40 and £20, and the Rymer prize of £5 5s., the examinations for which are held in May and October. The fee for four years' full curriculum, including lectures, is £75 10s. 0d.

For qualified men the two years' training in dental mechanics, required by the R.C.S. Curriculum, can be taken in the Mechanical Laboratory, and there is a "Compositon Fee" including all the dental subjects of the curriculum of £4 10s.

Medical students are admitted to the practice of the Dental Department in general hospitals to which no medical school is attached, but each contains over 100 beds. Detailed particulars will be supplied on application to the various secretaries.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham.—This hospital contains medical and surgical wards and a ward for children, having 245 beds, with a very large out-patients department. It prides itself especially limited to post-graduates. There are special departments for gynaecological cases, diseases of the eye, ear, throat and nose, medical electricity and radiography, and skin diseases. It is authorised by the University of London to give certificates of post-graduate study for the M.D. and M.S. degrees.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway Road, N.—This institution has been greatly enlarged, contains 185 beds, cases in various special departments are treated and there is an annual hospital study during the fifth year by the Joint Board. The Pathological Department has been extended and a Director of Clinical Pathology appointed. The practice of the hospital is open to practitioners and senior students, and clinical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

BETHLEM ROYAL HOSPITAL.—In this Royal institution only cases of lunacy are received, and students intending to pursue this special branch have the best possible opportunities afforded here. The hospital contains 500 beds, and two resident house physicians who have recently obtained their diplomas to practise medicine and surgery are elected every six months and are provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. The students of certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of two mornings a week, and will receive an honorarium of 1 guinea for each lecture. Lectures are also given.

NATIONAL HOSPITAL FOR EPILEPSY AND OTHER DISEASES OF THE NERVOUS SYSTEM, Queen Square, W.—Contains, with its country branch, 200 beds and cots. It is recognised by the Conjoint Board, and all its beds are exclusively devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, Portland Place, Welbeck Street, W.—Graduates in medicine and senior students may attend demonstrations in the Out-patient Department. No fees are charged. The Savill Prize and Medal is awarded to the student who makes the best essay—examination and presents the best thesis after attending at least 25 demonstrations.

LONDON TEMPERANCE HOSPITAL.—This Institution is situated in the Hampstead Road, and contains 100 beds, and is conducted, as its name implies, on non-alcoholic principles. The hospital is a general hospital, and the medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant officer.

METROPOLITAN HOSPITAL, Kingsland, N.E.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the Metropolis, and contains 253 beds, besides 18 beds at a convalescent home. It is a general hospital, with a large medical and surgical staff, in which various special departments for the treatment of diseases of the eye, throat, ear, diseases of women, &c., will be found.

SPECIAL HOSPITALS

HOSPITALS FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 373 beds in the two buildings. There are six house physicians who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays at four o'clock, save during the vacations. Terms, £2 2s. for three months; £5 3s. perpetual. A special course of instruction in the diagnosis of consumption, for which the department will hold the certificates, will be held in November. This hospital is recognised by the Conjoint Board, the University of London, and the Apothecaries' Society.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and well-equipped hospital at the East End, containing 170 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; for six months' attendance, 3 guineas.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY ROAD.—This hospital, which has lately undergone extensive re-organisation, provides an excellent field for research and study in diseases of the chest, more especially tuberculosis, and in various departments. The departments in which study can be pursued comprise the in-patient, out-patient, Röntgen-ray, cardiological, pathological and bacteriological, ear, nose and throat, and dental departments. At the hospital is a medical school for instruction in diseases of the chest, more especially tuberculosis, at which courses of instruction are given from time to time. There is also a tuberculosis school for nurses, where regular theoretical and thorough practical courses of instruction are given, for which a certificate is granted. The fees for attending the clinical practice of the hospital are as follows:—One month, one guinea; three months, three guineas; one year, 10 guineas; three years, 3 guineas; perpetual, 10 guineas.

For further information apply to the Dean, Dr. Barry King.
THROAT AND EAR HOSPITALS.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.—This hospital was founded in 1838 and is situated in Fitzroy Square. The out-patient department is open daily at 2.30 p.m. to practitioners and students desirous of acquiring clinical instruction and technical knowledge. Operations are performed on in-patients on Tuesdays, Wednesdays, and Fridays from 10 a.m. to 1 p.m. Fee for one month’s attendance at the hospital one guinea, and for three months two guineas. (See advt.)

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square, W.—This hospital contains 48 beds. Clinical instruction is given daily in the Out-patient Department on diseases of the nose, throat, and ear, and systematic courses of lectures are given during the winter session. There are nine clinics weekly, and an annual otoscopic attendance of nearly 5000. Major and minor operations daily (Mondays excepted) in different theatres. Thirty-six junior clinical assistants are appointed from among the students to assist the surgeons. Students are admitted to the practice of the hospital at the following fees:—Three months £5 5s.; six months £7 7s.; longer periods, £10. Further details can be had by applying to the Hon. Med. Secretary.

CENTRAL LONDON THROAT AND EAR HOSPITAL. This hospital contains accommodation for 200 in-patients. It has a very extensive out-patient department (over 50,000 attendances yearly), which is open daily to all medical practitioners and students, for the purpose of clinical demonstration and instruction. Consecutive operations are given twice weekly by members of the staff, which are open to qualified practitioners and advanced students. Each course is of about seven weeks’ duration, and includes hospital attendance for that period. Operations are performed daily (Saturday and Sunday at 1 p.m.). Special attention is devoted to scientific work in the newly equipped laboratory. Full particulars will be supplied on application to the Dean.

WOMEN AND CHILDREN.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road was established about 30 years ago as the North-Eastern Hospital for Children. It has 130 beds in London and 30 at its Seaside Branch, Bexhill. Courses of Post-Graduate Lectures and Demonstrations are given by the Medical and Surgical staff during the winter, which are free to Practitioners and Students of Medicine.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Bloomsbury, and Cromwell House, Highgate, is the largest children’s Hospital in the United Kingdom, and contains 240 beds. The hospital is open to qualified medical men, and to students who have completed four years of medical study, the Hospital having been recognised by the Joint Board of England as a place where six months of the fifth year may be spent on clinical work. There are special ophthalmic, urological, dental, and surgical departments. There is also a Museum and Library in connection with the School. Fee for three months’ general hospital attendance, £7 5s.; perpetual, £10 10s.; £1 1s. for students satisfying the requirements of a Register of Practitioners. The lecturer’s room is situated on the third floor, in a special ophthalmic theatre of upwards of 70 beds, with a postgraduate ward of 40 beds. Operations are performed daily, or for not less than three months. Ophthalmological Clinics: Clinical clerkships are appointed once a month; fees, £1 1s., for a month’s attendance. Facilities are afforded for obtaining theoretical and practical instruction in the central and peripheral parts of the eye, and for a period of daily attendance in the Pathological Laboratories, the fees for which are: For one month, £1 3s.; for three months, £6. In addition to the ordinary practice of the hospital, Special Classes illustrated by cases, specimens, slides, charts, operations, etc., are arranged to extend over six weeks of each session. Further details and full syllabus may be obtained by application to the Dean or the Secretary of the hospital. Fee for each course of six lectures, £1 1s.

Special Courses of Instruction are given throughout the year as follows: Mondays and Thursdays, 4 to 5 p.m., "Pathological Investigation of Diseases of Childhood." Tuesdays and Thursdays, 3 to 6 p.m., "Minor Surgical Operations of Childhood." Tuesdays and Fridays, 2.45 to 4.15 p.m., "General Surgical Diseases of Childhood." Fee for six attendances, £1 1s.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone Road, N.W.—Qualified medical practitioners and medical students are admitted to the practice of this hospital. Certificates of attendance are given by all universities, colleges and licensing bodies. Fee for the course of four weeks, £8 8s. Students are accommodated at the new Residential College (5 Cosway Street) opposite the hospital.

Arrangements have also been made for the preliminary instruction in midwifery now required by the General Medical Council. This will include:—(1) Practical instruction in the methods of examination of pregnant women, (2) delivery of seven months’ duration, under the direct supervision of a medical officer of the hospital; (3) practical instruction in the treatment of the mother and child during the puerperium, including clinical and domiciliary work; (4) examination four times weekly by the visiting medical staff. Fee for this special course, £5 per month. (See advt.)

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell.—This institution was founded about sixty years ago in one of the poorer quarters of the East End of London and contains 124 beds, with specialпалаты for electric treatment, ophthalmic and dental surgery, etc. Two Clinical Clerkships are available, and the Hospital is recognised by the Joint Board for England.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—This important institution, situated in South London, has been rebuilt and appointed on completely modern lines and now provides 100 beds, with an excellent Medical and Surgical Staff.

The SAMARKAN TEE HOSPITAL FOR CHILDREN, Marylebone Road, N.W., has 67 beds, and offers excellent opportunities to qualified medical men for clinical study and training in the details of operative gynaecology. Fee: Three months, £3 3s.; further particulars will be supplied by the staff in this department has gained for them a European reputation.

The HOSPITAL FOR WOMEN, South Sq.—The Hospital contains 67 beds. In connection with this institution there is now an organised school of gynaecology open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed. Fee for three months’ course, and certificate, £8 8s.

CHELSEA HOSPITAL FOR WOMEN, Fulham.—This institution contains 30 beds, and is served by a staff of considerable experience. There is a Convalescent Home at St. Leonards, in which 22 additional beds are at the disposal of the authorities.

EYP HOSPITALS.

ROYAL EYE HOSPITAL, St. George's Circus, Southwark, S.E.—There are 40 beds and two cots at this institution. Lectures, demonstrations, instruction in refractive work, and demonstrations on the specimens in the Museum are given throughout the year by the teaching staff. Patients are seen in the out-patient department and operations are performed in the theatres daily, and the requirements of a Register of Practitioners. There are annually upwards of 21,000 new out-patients attending the Hospital. Fees for Three months’ practice and tuition, £3 3s.; perpetual, £5 5s. Further particulars of the Dean. (See advt.)

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, adjoins Charing Cross Hospital in King William Street. It has about 40 beds and a very large out-patient clinic. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and junior students. Fee, six months, £3 3s.; perpetual, £5 5s.

ROYAL LONDON OPHTHALMIC HOSPITAL, formerly in Moorfields, and recently rebuilt in the City Road, is the largest hospital devoted to this speciality recognized by Britain, and contains 138 beds. Students and practitioners are admitted to the practice daily at 9 o'clock. Operations, 10 o'clock and after. Fee for six months,
SKIN HOSPITALS.

ST. JOHN's HOSPITAL FOR DISEASES OF THE SKIN.—Out-patient department, 49 Leicester Square. In-patient department, 62 Uxbridge Road, W. This hospital has a well-equipped in-patient department, with 40 beds. It has a School of Dermatology at 49 Leicester Square, which is conducted by the medical staff of the hospital. During the past year the free course of Chesterfield Lectures have been well attended. The Out-patient Department has been reduced in cost to £10,000, and contains a spacious laboratory and special electrical department which can be seen in operation every afternoon except Saturday. Special Courses in Pathology and Bacteriology can be arranged for in the laboratory. Departments are given every day at 2 p.m., on Selected Cases.

THE WESTERN SKIN HOSPITAL.—This is one of the oldest institutions of the kind in the metropolis, and was started as long ago as 1837. It has recently been rehoused in large and commodious premises in the Hamilton Road, and the practice of the hospital is open to students and practitioners, who have the opportunity of seeing daily a large number of out-patients.

THE HOSPITAL FOR DISEASES OF THE SKIN, Stamford Street, Blackfriars.—This was the first hospital to be established for the treatment of cutaneous disorders in London. It has an extensive out-patient department, which is open to qualified practitioners. This year an evening clinic has been opened for the convenience of patients. A fine inner court has lately been acquired in the Blackfriars Road, whither the hospital will shortly be moved, and in the new buildings it is hoped to add a few beds.

METROPOLITAN POST-GRADUATE INSTITUTIONS.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—At the lectures and clinics, at which illustrative cases are specially selected, one hour is devoted to clinical teaching, and is adapted to suit the busy practitioner, and one has the opportunity of meeting other practitioners who are interested in the same subject. The subscription is one guinea per annum. Special facilities are afforded to those desirous of attending hospital practice. A time-table of clinics at the general and special hospitals is kept, and the Secretary makes all necessary arrangements. For those who wish to acquire the necessary skill to enable them to use some of the most important forms of apparatus, such as the cystoscope, sigmoidoscope, larynscope, X-rays, high-frequency currents, electricity, etc., special arrangements have been made so that each practitioner may receive practical personal instruction in the use of these apparatuses in different departments of the hospital. There are special practical classes in such subjects as bacteriology, pathology, microscopy, gynæcology, otoLOGY, etc. There is a well-equipped clinical laboratory attached to the college, under the superintendence of an expert medical officer. Special instruction is given in all branches of clinical practice, pathology, bacteriology, vaccines, etc. There is a special department, which enables subscribers to have specimens examined, vaccines prepared, etc., at moderate fees. The Polyclinic is not confined for its teaching staff to any one medical school or hospital, but includes teachers from all the best general and special hospitals in London. Full information may be obtained from the Medical Superintendent, Medical Graduates' College, 22, Clarges Street, Grosvenor Street, W.

WEST LONDON POST-GRADUATE COLLEGE.—The West London Hospital, Hammersmith, contains 160 beds; the post-graduate course was started in 1895. Instruction is given in the out-patient department daily at 12.30, and in the wards at the request of the doctors and assistant surgeons. The physicians and surgeons attend daily at 2.30 p.m., when post-graduates can accompany them in their visits to the wards. Operations are performed daily at 2.30 p.m. Demonstrations are held every morning and afternoon. There are long despatches evening at 5 p.m. (Saturdays excepted). Special classes are held in bacteriology, vaccine therapy, diseases of the eye, throat, X-rays, anaesthetics, intestinal surgery, tropical medicine, cystoscopy, vaginal and operative surgery, etc.—No information vouchsafed.

PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM.—This hospital contains medical and surgical wards and a ward for children, having 125 beds, with a very large out-patient department. It is exclusively limited to post-graduates. There are special departments for gynaecological cases, diseases of the eye, ear, throat, nose, and medical electricity and radiography, and skin diseases. It is authorised by the University of London to give the degree of post-graduate in the M.D. and M.S. degrees.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.—This post-graduate school is established in connection with the Prince of Wales's General Hospital, Tottenham, N., which is recognised by the University of London as an educational centre of post-graduate study for the M.D. and M.S. degrees.

The following are some of the principal provincial hospitals having the greatest number of beds, to which students are admitted, where clinical instruction can be obtained, but to which there is no medical school attached—

BATH ROYAL UNITED HOSPITAL, Bath.—This hospital contains 150 beds and possesses an extensive library. Considerable alterations and re-arrangements have been carried out in the out-patient department during the past year, and also a complete installation of heating by hot water.

**The Irish Medical System.**

The system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, well-equipped, which educates the students of that hospital and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with Trinity College), and a student of any school is free to enter for the whole or any part of his course at any school or hospital he pleases.

**Cost of Medical Education in Ireland.**

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this connection the following tables may be of use to the prospective student:

**Cost of Medical Education.**

| School of Physic, Dub., Univ. | £122 17s. |
| Royal College of Surgeons School | £124 19s. |
| University Colleges | About £125. |
| Queen's University, Belfast | £105 |
| **Cost of Diplomas or Degrees.**
| Dublin University | £75; for this must be added £83 4s., the cost of obtaining an Arts degree. |
| National University, Ireland | £75. |
| Queen's University, Belfast | £101 19s. |
| Conjoint Royal Colleges | £47. |
| Apothecaries' Hall | £22 1s. |

Thus, the absolute payment will amount to somewhere between £125 and £235 Is, according to the course chosen. For the Conjoint Colleges the entire cost is £166 19s, taking the maximum mode of payment. So that, assuming that extras or voluntary costs are incurred the total will vary, say, from £170 to £200. "Grinding," although not officially recognised, occupies a position similar to that of the extra-mural instruction of other schools. Its cost must be reckoned among the expenses of the course, for, while not essential, it has become customary for almost all students to obtain aid in their studies in this way. As a rule, this private instruction costs about £5 5s. for each of the four examinations.

The above sum, or something like it, may be expended by the student or his parent in paying for lectures, &c., and examination fees as they fall due, and there is no difficulty in obtaining the necessary information for his guidance if he likes to pay for his course this fashion.

All the schools require fees for each course to be paid in advance. Women are admitted to all the courses, degrees, and licences on the same terms as men.

**Date of Entry.**

The entry of names and commencement of study in Ireland is suspended to date from the 1st of October in each year, but entries are accepted up to the end of that month, or in some schools even later. It should be remembered that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures delivered, and if he loses any time at the beginning, he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o'clock, and occupying this by lectures and dissections. His vacations are a fortnight at Christmas and a fortnight at Easter, and the academic year ends at the end of June.

**Preliminary Examinations.**

The first act of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets
a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35 Dawson Street, Dublin, unless, as is usually the case, this duty is undertaken by him for the school registrar. He is then entitled to become a Regius Registrar of Medicine, and is free from all fees, and his period of study counts from that date. He must register at the earliest possible moment, or he may lose credit for his work.

The only preliminary examination held specially for medical education held currently by the Royal Colleges of Physicians and Surgeons, but other examinations—e.g., the public entrance at Trinity College, the matriculation of the National and Queen’s Universities, the Intermediate Examination passes in the required subjects, and certain other examinations recognised by the General Medical Council, are accepted as equivalent.

The subjects of examination as prescribed by the General Medical Council are as follows:—1. English language, including a specified author, dictation, grammar, and composition; also parsing and analysis from a book specified. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (a) arithmetic, including vulgar and decimal fractions; (b) algebra, including simple equations; (c) geometry, Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects:—(a) Greek, (b) French, (c) German.

The Irish Licensing Bodies.

The Medical Licensing Bodies of Ireland are five in number, and, as a rule, students will gravitate into one or other of six classes:—a. Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. b. Those who take the conjoint licence of the Royal Colleges of Physicians and Surgeons. c. Those who take their qualifications at the National University of Ireland, where graduation in Arts is a requisite. d. Those who enter Queen’s University, Belfast, and take their course and degrees there. e. Those who take the licence of the Apothecaries’ Hall. f. Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomas, as our epiteome must necessarily be insufficient for the information of the student, and we can occupy our available space with more useful matter. Since no other official information upon which students may depend can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

The University of Dublin.

The University of Dublin grants the degrees of M.B., B.Ch., and B.A.O. to students who have obtained their B.A. degree, and who have been for at least five academic years on the books of the Medical School, and the higher degrees of M.D., M.Ch., and M.A.O. to graduates of certain standing who hold the degrees of M.B., and B.Ch. It does not grant degrees to any but graduates in Arts, and consequently its degrees hold a high rank, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O. is approximately as follows:—Lectures, £5 4s. 0d.; Hospitals, £3 13s. 0d.; Degree Fees, £2 7s. 0d.; Total, £19 17s. 0d.

The expense of the B.A. degree, amounting altogether to £83 4s., should be added, making the total cost £223 11s. 0d.

Diploma in Medicine, Surgery, and Midwifery.—Candidates for the Diploma in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in medical studies. The medical course and examinations are the same as for the degrees. Fees for the diplomas in medicine, surgery, and midwifery, £21. A diploma on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor of Medicine on paying the degree fees.

In addition to its ordinary qualifications the University grants the degree of Doctor of Medicine.—To obtain this the candidate must have passed the final examinations, and be of M.A. standing. He must then read a thesis before the Regius Professor of Medicine. Fee for this degree, £5.

Master Surgery.—The candidate must be a Bachelor in Surgery of three years’ standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead body), and then pay the fee for the Master in Obstetric Science. The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the course for M.B., B.Ch., a course of obstetric medicine and surgery. He is then required to pass an examination in the following subjects:—Practice of midwifery, gynaecology, anatomy of female pelvis and elementary embryology, and clinical gynaecology. Fee for this degree, £5.

Diploma in Public Health.—The candidate must in a Registered Medical Practitioner; must have completed, subsequent to obtaining a registrable qualification, four months’ practical instruction in a laboratory in practical work in chemistry and bacteriology applied to public health; he must have passed the preliminary practical work for six months under an approved officer of health; and have attended, after qualification, for three months, the practice of a hospital for infectious diseases.

Degree in Dental Science.—Candidates for the D.Dent.Sci. degree in dental science must have taken a degree in Arts, and must have had their names in the books of the Medical School for four years. Three examinations must be passed—namely, the Preliminary Scientific at the end of the first year, the Intermediate at the end of the third year, and the Final Dental at the end of the fourth year. The total fees are £280 2s.

Full particulars regarding the Medical and Dental Courses and a prospectus of the Courses for the Diploma in Public Health may be obtained by application to the Registrar of the School of Physx, Trinity College, Dublin.

Queen’s University, Belfast.

The Queen’s University confers the degrees of M.B., B.Ch., and B.A.O., on students who have followed the prescribed course of studies for five academic years, and passed the prescribed examinations. At least three of these years are to be spent on courses at the University. The expense is about £20.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least six academic years, or, in the case of graduates of the University in Arts or Science, of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued an original work, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (a) after an examination, which includes written, oral, clinical, and practical examinations; or (b) on the submission of the thesis in lieu of the above study or research, to be approved by the Faculty of Medicine, after an oral or other examination of the candidate on the subject thereof. On application for these degrees a fee of £2 2s., and on admission to the faculty, £10, must be paid.

The subjects of the examination for the degree of M.D. are:—The Principles and Practice of Medicine, and one other special subject to be selected by the candidate from: (i) Human Anatomy, including Embryology; (ii) Physiology; (iii) Pathology; (iv) Pharmacology and Therapeutics; (v) Sanitary Science and Public Health; (vi) Forensic Medicine and Toxicology; (vii) Mental Diseases.

The subjects of the examination for the degree of M.Ch. are:—(r) Surgery, Theoretical and Practical,
including Ophthalmology and Otology. (2) Surgical Pathology. (3) Surgical Anatomy and Operative Surgery, with the use of surgical instruments and appliances.

The subjects of the examination for the degree of M.A.O. are:—(1) Midwifery. (2) Diseases of Women, and Children. (3) Pathology in its special bearing on Midwifery and Children. 

**Diploma in Public Health.**—This diploma is given after examination to registered medical men, on similar conditions to those obtaining elsewhere.

**NATIONAL UNIVERSITY OF IRELAND.**

The National University of Ireland confers the degrees of M.B., B.Ch., and B.A.O., on students who have followed the prescribed course for five academic years, and passed the prescribed examinations. At least three years must be spent at one of the constituent colleges of the University, viz., the University Colleges at Dublin, Cork, and Galway. The University also confers the higher degrees of M.D., M.Ch., M.A., B.Sc. (Public Health), D.Sc. (Public Health), B.D.S., and M.D.S.

The course of obtaining the degrees of M.B., B.Ch., and B.A.O., is approximately:—Lectures, £68 5s.; Hospitals, £50 £; University Fees, £19. Total, £143 10s.

The conditions for the higher degrees are:—

**Doctor in Medicine.**—Candidates may present themselves for the examination for this degree after an interval of three academic years from the time of obtaining the M.B., B.Ch., B.A.O. degrees; but in the case of candidates who have obtained a degree of the University in the Faculty of Arts, an interval of two academic years is sufficient.

Candidates must at the same time produce a certificate of having been, for at least two academic years, engaged in hospital or private medical, surgical, or obstetrical practice respectively, or in the military or naval service.

Candidates at this examination must answer in Medicine and Pathology.

The examination in each subject consists of:—

(a.) A Written Examination.

(b.) An Oral Examination.

In addition every candidate must diagnose at the bedside at least three medical cases, and prescribe treatment. He must also write detailed reports on at least four cases of hospital or private medical, surgical, or obstetrical practice respectively, or in the military or naval service.

**Master in Surgery.**—The following are the subjects of examination:—

Surgery, theoretical and practical, including Ophthalmology and Otology; Surgical Pathology; Surgical Anatomy and Operative Surgery, with the use of Surgical Instruments and Appliances.

The other conditions are the same as for the M.D. degree.

**Master in Obstetrics.**—Academic standing is as for the two previous degrees.

Each candidate must furnish satisfactory evidence that since graduating in medicine he has (1) had personal charge of at least thirty cases of labour; and (2) attended during the period of three years the practice of a clinical hospital for diseases of women, where at least six beds are in constant occupation, or in a special ward of a general hospital, where such cases only are treated and containing at least six beds in constant occupation.

Candidates at this Examination must answer in the following subjects:—Midwifery, Diseases of Women and Children, Pathology, the Use of Instruments and Appliances, and Obstetrics. A candidate must present himself at the examiners.

(b) an Oral Examination, with practical illustrations, including the use of instruments and appliances; (b) a written Examination; (c) a clinical Examination, as far as practicable.

**Bachelor of Science in Public Health.**—A candidate shall not be admitted to receive the Degree of Bachelor of Science, Public Health, unless he:—(a) shall have received the Degrees of M.B., B.Ch., and B.A.O. at least one year previously; (b) shall have

pursued an approved course of study in the Faculty of Medicine; and (c) shall have passed the prescribed examinations.

**Courses.**—In addition to D.P.H. Course:—(1) Special Pathology (three months). (2) Bacteriology, second course (three months). (3) Advanced Course in Midwifery (three months). 

**Doctor in Public Health.**—The regulations are not yet published. Fee, £10.

**Diploma in Public Health.**—This Diploma may be granted to matriculated students of the University who shall have completed one year's study, approved for the purpose, and shall have passed the prescribed examinations: provided that it shall not be granted except to a registered medical practitioner.

The conditions and examination are similar to those already in force for the University of Dublin.

**Diploma in Dentery.**—Candidates for the Degree of B.D.S. shall be required to pass, after matriculation, four University Examinations, namely:—A First University Examination in Medicine, as for medical students; for Instruction in these subjects. We recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Surgeons, or to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary of the examination to be held in Dublin, and the fee, £124 10s., makes altogether £166 10s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination.

The Colleges also confer a Diploma in Public Health, of which information will be found on page 277.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.**

Examinations are held conjointly by the two Colleges. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third and final years. These examinations are conducted by examiners chosen by each of the Colleges for the subjects appropriate to them. Each of the curriculum has recently been revised, and made of a more practical form. As in the English Colleges, the subjects of the First Professional Examination may be studied either at a medical school or at an institution other than a medical school which is recognised by the Colleges, after due inspection. As in the English Colleges, students are required to pass at the end of the first or second years, as the case may be, the Preliminary Examination of the Royal Colleges of Physicians and Surgeons, and to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary. In the case of the Final Examinations, the fee, £42, and the maximum term of residence, 14 years, in any one of the Colleges, makes altogether £50 10s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination.
IRELAND—EDUCATION.

THE MEDICAL PRESS. 277.

President may appoint. Fee to Licentiates of the College, £21, to others £30. Ir.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This College grants a Licence in Surgery to registered medical practitioners.

The subjects, methods, times, and places of examination are those of the surgical group of the Final Professional Examination of the Conjoint Board in Ireland of the Royal College of Physicians and the Royal College of Surgeons. (See their regulations.) Candidates must pass in all the subjects at one examination. Special examinations will not be granted under any circumstances.

Candidates may be registered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and examinations equivalent to those required by the regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an examination in Arts recognised by the Council, may, upon application, be admitted to the examination.

Candidates are required to lodge their applications, declarations, and certificates with the Registrar, at least twenty-one days before the date of the examination.

The fee for examination is for each admission five guineas. Of these fees five guineas will be reckoned as part of the fee payable upon admission to the Licence in Surgery. The fee to be paid upon admission to the licence in Surgery will be four guineas.

Fees will not be returned under any circumstances.

All applications with reference to the examination for the Licence in Surgery should be addressed to the Registrar, Royal College of Surgeons in Ireland, Dublin.

Fellowship.—The examination for the Fellowship is divided into two parts—viz.: The Primary and the Final. The subjects of the primary examination are—anatomy, including dissections, physiology, and histology. The examination is partly written, partly oral, and partly practical. Candidates must pass in all the subjects at one examination. The subjects of the final examination are—Surgery, including surgical anatomy, and pathology. The examination is partly written, partly oral, and partly practical. Candidates must pass in all the subjects at one examination. The examinations are held three times in each year, commencing—The primary on the first Monday in March, the third Monday in July, and the third Monday in November. The final on the second Monday in March, the third Wednesday in July, and the fourth Monday in November. Special examinations will not be granted under any circumstances. Candidates are required to lodge their applications, certificates, and receipts for fees with the Registrar, at least seven days before the date of the examination.

Fees.—1. The fees for examinations are as follows:—

Primary examination, each admission, 5 guineas:—final examination, each admission, 5 guineas. 2. Of these examination fees ten guineas will be reckoned as part of the fee payable upon admission to the Fellowship. 3. The fee to be paid upon admission to the Fellowship is forty guineas, except when the candidate is a Licentiate of the College, in which case the fee is twenty-five guineas.

All applications with reference to the examinations for the Diploma of Fellow should be addressed to The Registrar, Royal College of Surgeons in Ireland, Dublin.

Dental students by the General Medical Council. They must have been engaged during a period of two years in acquiring a practical familiarity with the details of mechanical dentistry under the instruction of a registered dentist, or under the direction of the superintendent of the mechanical department of a recognised hospital where the arrangements for teaching mechanical dentistry are satisfactory to the Council of the College. This instruction may be commenced or attended before the candidates register as medical or dental students. They must have been engaged during the four years in the acquirement of professional knowledge subsequently to the date of registration as a medical or dental student.

One year's bona fide apprenticeship with a registered dental practitioner, after being registered as a medical practitioner, is an essential condition of the fourth year of professional study. Candidates must produce evidence of having followed a prescribed course of study. There are special exemptions in the case of persons already holding a surgical or dental qualification.

All applications with reference to the examination for the fee, Diploma of Fellow in Surgery, should be addressed to The Registrar, Royal College of Surgeons in Ireland, Dublin.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having completed the course of study as laid down in the curriculum, and pass the necessary examinations. The diploma of this apothecary may, in the discretion of the Council, be granted to the holder to be registered as a practitioner in medicine, surgery, and midwifery, and possess the privileges of an apothecary.

There are three professional examinations, the total fees for which amount to thirty guineas. Women are eligible for the diploma.

Registered medical practitioners receive the diploma of the Hall upon passing an examination in the subject or subjects not covered by their previous qualification, and on paying a fee of fifteen guineas.

The fees payable for each examination are as follows:—Professional Primary, £5 5s.; Intermediate, £10 10s.; Final Examination, £15 15s.

Applications and schedules, together with bank receipt for the fee, must be lodged with the Registrar, Apothecaries' Hall, 40 Mary Street, Dublin, at least fourteen clear days before the day of examination.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21.

The candidate must produce evidence of having passed before entering on medical studies passed a preliminary examination in general education.

The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary Street, Dublin.

THE DIPLOMA IN PUBLIC HEALTH.

The diploma is granted by Dublin University, the National University, Queen's University, and the Conjoint Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in:—(1) Chemistry (including chemical physics). (2) Engineering and architecture. (3) Ordinary law, excepting penal statutes. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommend that all candidates shall have studied in a special bacteriological laboratory, also for six months as pupil of a working medical officer of health. The examinations are preceded by a report of the medical officer of health of a county or of one or more districts having a population of not less than 30,000, or a medical officer of health who is a teacher in Public Health of a recognised medical school.

THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows:—

The School of Medicine, Trinity College, Dublin.—No student is permitted to matriculate unless he has passed the Necessary Examination of Trinity College, or some other examination recognised by the General Medical Council. Two medical scholarships are given.
annually at the School of Physic, value £20 per annum, for two years; the examinations for which are held in Anatomy and Botany, and the candidate who obtains the highest aggregate marks in Anatomy and Botany, and in Botany and institutes of medicine; the other in zoology, chemistry, botany and experimental physics. A travelling prize of £100 is awarded by the Board to the successful candidate at a special examination in anatomy and physiology, held annually. The Board has decided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery abroad. The examination is held in June, and is open to students who have passed the Final Examinations in Medicine or Surgery, but in no case may be, within two years of the examination.

The Sir John Banks Medal and Prize, founded by the late Sir J. Banks, M.D., formerly Regius Professor of Physic, are awarded to the best and second best answerers at the Medical Travelling Prize Examination.

The Edward Halloran Bennett Medal and Prize, founded by pupils of the late Dr. E. H. Bennett, formerly Professor of Surgery, are awarded to the best and second best answerers at the Surgical Travelling Prize Examination.

Class prizes are given at the end of the session of between £5 and £10 in value. The John Mallet Purser Medal, founded by Prof. Purser’s past pupils, is awarded to the student who obtains the highest aggregate marks at the five sections of the Final Examinations, provided that he has completed his medical course in the prescribed period of five years.

There is a complete School of Dental Science in connection with the School of Physic, Trinity College. Lectures are given in anatomy, chemistry, surgery, physics, physiology and histology, dental anatomy, dental mechanics, orthodontia and anesthetics.

Post-Graduate Classes.—A short post-graduate course is now given annually in September in connection with Trinity College Medical School. It includes special work on Diseases of the Eye, Nose, and Throat, Gynaecology, Diseases of the Skin, X-ray work, Medicine, Surgery (clinical and operative), and Clinical Pathology and Applied Physiology.

All classes are open to women and to external students as well as to students of the University.

The Royal College of Surgeons in Ireland, Schools of Surgery.—These schools are attached by Charter to the Royal College of Surgeons, and have existed as part of the College for over a century. They are carried on within the College buildings, and are subject to the supervision and control of the Council. The buildings have been reconstructed, the capacity of the dissecting room now providing for pathological surgical, pathological dental, gynaecological, public health, chemical, and pharmaceutical laboratories fitted with approved appliances, in order that students may have the advantage of modern methods of instruction. There are special rooms set apart for women students.

The lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the College.

All the diplomas of the College are open to students of either sex. Separate rooms have been provided, and made for the instruction and comfort of women students.

Prizes.—The Barker Prize, £26 6s.; the Carmichael Scholarship, £1; the Mayne Scholarship, £5. The Gold and Silver Medals in Surgery and the Stoney Medal in Anatomy.

Class Prizes of £2 and £1, accompanied by silver medals if sufficient merit is shown, will also be given in each subject. Prospectus and Student’s Guide are obtainable on application to the Registrar, Royal College of Surgeons in Ireland.

UNIVERSITY COLLEGE, DUBLIN.—This College is a constituent college of the National University of Ireland, for whose examinations and degrees it trains students. The examinations are conducted by the professors and examiners of the college, in conjunction with external examiners appointed by the University.

Medical students must be registered with the Branch Medical Council at the commencement of their period of study. Forms of application can be obtained and may be filled up by any inhabitant of Ireland. No conditions for registration may be obtained from the Registrar of the College at the Medical School. The student must bring with him the certificate of his Matriculation examination, or of the Senior Grade of the examination of the Institution for which he is registered, to the Branch Medical Council in the necessary subjects, and his birth certificate.

Non-matriculated students intending to study medicine must have passed a Preliminary Examination, accepted by the General Medical Council, in English, Latin, Mathematics, and a Modern Language or Greek.

Intending medical students who, for any reason, cannot begin the study of Medicine in the Winter Session, may do so in the Summer Session, but will not be able to take the Anatomical examination until the first medical year, until the following Winter Session.

The Scholarship Regulations provide for Five Scholarships of £30 each, tenable for one year in each of the 2nd, 3rd, 4th and 5th years of study. The Examination for these scholarships is held in October, with the subjects being those to which no component examination applies which Candidates must have attended in the College. Scholarships tenable for one year are offered at entrance at an Examination common to all Faculties.

There are Examinations of the value of £20 and £10 offered by the College for the several classes at each Medical Examinations of the University; and a Gold Medal to the most distinguished answerer at the M.B., B.Ch., and B.A.O. Examinations of the year.

Courses of lectures in Dental Surgery and Dental Mechanics are given to Dental students.

THE QUEEN’S UNIVERSITY OF BELFAST.—This University provides all the classes required for a complete medical curriculum. The University contains laboratories in connection with the departments of Biology, Chemistry, Physiology, Pathology, Anatomy, Physics, and Materia Medica. In connection, too, is a Students’ Union, which gives students the advantage of dining-rooms, reading-rooms, and the free use of library and laboratory.

Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago, and has 300 beds, and at the Mater, which has 150 beds. Other hospitals open to the dissecting rooms of the University are: The Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Bell Ulster Eye, Ear, and Throat Hospital, the Union Infirmary and Fever Hospital, the Fever Hospital,浦儒夏, and the District Lunatic Asylum.

Scholarships.—(1) Twelve Entrance Scholarships, value £20, given to students of Art, Science and Medicine; (2) two Dunville Scholarships (each alternate year), value £20 each; (3) one Andrews Studentship each alternate year, value £145; (4) numerous sessional prizes.

Sixteen scholarships, value £10-£20, are now open for competition at the remains of medical examinations in March and June. Each year a Magrath Clinical Scholarship value about £108. There is also a Post-Graduate Research Fund open to all graduates of not more than three years’ standing. Information regarding these scholarships, etc., may be obtained on application to the Secretary of the University.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen’s University of Belfast is, approximately, £100. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the
Mater Infirmorum Hospital, but not fees for the special hospitals.

IRELAND—

Certificates in several of the academic institutions educate students for all degrees and licenses, and are maintained, as hitherto, by Government grants. Various exhibitions and scholarships are available. Each college has the disposal of about £1,500 per annum.

THE UNIVERSITY COLLEGES—CORK AND GALWAY.—There are now constituent colleges of the National University of Ireland, and conduct examinations admitting to its degrees.

UNIVERSITY COLLEGE, CORK.—The arrangements in the Faculty of Medicine are made chiefly with reference to the requirements of the National University of Ireland, but students proceeding for the degrees of Fellow of the Royal College of Surgeons in England, Scotland, or Ireland, can arrange the course of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance in the college are also acceptable to the University of London. The total fees for the college lectures and hospital attendances required by the National University of Ireland are about £604.

Clinical instruction is given at the North and South Infirmaries and the Union Hospital. Students can also attend the Mercy Hospital, the County and City of Cork Lying-in Hospital, the Maternity Hospital, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The winter session commences October 1st, and ends at the end of April. The courses of the summer session are delivered in the months of April, May, and June.

Between forty and fifty scholarships open to Medical Students are awarded annually (values £20-£70), as well as the Blayney Scholarship. This Scholarship, worth about £32, will be awarded to the candidate obtaining the highest marks in Honours at the M.B., B.Ch., B.A.O. Examination, held in Autumn at the College.

Further information can be obtained in the College Regulations, or on application to the Registrar, University College, Cork.

UNIVERSITY COLLEGE, GALWAY.—Clinical teaching is carried on in the Galway Hospital, established as a Public General Hospital (in the place of the County Galway Infirmary) by Act of Parliament 1852. The Galway Fever Hospital and Galway Union Hospital are also open to students. The conditions of residence required by the National University for graduation may be observed in Galway. The lectures qualify for the other licensing bodies.

P R I C E S.—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth year. There besides, private Foundation Scholarships open to medical students and tenable with medical scholarships. Sessional prizes are offered in each subject.

Like the sister college of Cork, this college is now a constituent college of the National University of Ireland.

ROYAL COLLEGE OF SCIENCE FOR IRELAND.

This College, situate in St. Stephen's Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of Agriculture, Chemical Manufactures, Engineering, Physics, and Natural Science. A Diploma of Associateship of the College is granted at the end of the three years' course. Non-associate students may join for any course required. There are several entrance scholarships, (a) in Agriculture, and (b) in Science and Technology, tenable for three years, of the value of £50 each yearly, with free tuition. There are four Royal scholarships of the value of £50 each yearly, with free tuition, tenable for two years, and two are tenable in these important subjects for associate students at the end of each session. All the laboratories and drawing schools are open daily for practical instruction. The Science Scholarship Examinations are held during the first week in July, and the Examinations for the first and second Scholarships in September, and the Entrance Examination for intending Associates in the third week of September. For further particulars and copy of college programme apply to the Registrar.

THE DUBLIN HOSPITALS.

The clinical hospitals in Dublin are ten in number, exclusive of three lying-in hospitals. There are also seven dispensary hospitals, an orthopaedic hospital, a fever hospital, an ophthalmic hospital, a dental hospital, and other special hospitals. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; and generally they have, without any special connection with any school. While, however, such association of school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is free to select either of them by any layman's wishes, and to change his hospital from year to year as he may see fit.

The Irish licensing bodies require attendance on hospitals for twenty-seven months—i.e., three winter sessions and four terms; and nine months' hospital work, within the five years of study. The fee for each general hospital is £8 8s. in winter, and for the summer £5 5s., or £2 12s. for the entire session of nine months if taken together. All the Dublin hospitals receive students as residents.

GENERAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—These hospitals contain over 300 beds. They are visited each morning at nine o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Instruction is also given on the principles of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There are ophthalmic, aural, throat, and gynaecological dispensary departments, and the instruction in these important subjects is given. A modern pathological laboratory, and a new mortuary have been opened recently. Twelve resident clinical clerks are appointed each quarter, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, but also to those who are qualified in medicine and surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected every six months, and are respectively £4 10s. and £2 12s. The Richmond Lunatic Asylum, containing 1,200 beds, adjoins the hospital.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.—This hospital was founded in 1752, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers, containing 40 beds, has recently been added. The certificates are recognised by all the universities and licensing bodies of the United Kingdom. Medical and surgical resident physicians and clinical surgeons are appointed every three months, and two house surgeons are elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the Secretary of the Medical Press, F.R.C.S.I., 32, Upper Pembroke Street.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS occupy a central position within a few minutes'
walk of the College of Surgeons and Trinity College. From October 1st, the physicians and surgeons visit the wards and give instruction at the bedside at the discretion of the authorities. There is a large detached fever hospital, and there are wards for infants and children. Operations are performed, at 10 a.m. on Tuesday, Thursday, and Friday. Special hours are devoted to clinical instruction in the wards, and a practice paper on general pathology and X-ray photography. Two House Surgeons are elected annually and four resident pupils half-yearly. Prize examinations for the Hudson Scholarship of £50 and a gold medal, and 1st and 2nd Prizes for surgical, medical, and dermatological prizes, are held at the termination of the session. The large dispensaries afford facilities for the study of ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Dr. H. T. Hewley, So Merion Square.

The Royal City of Dublin Hospital.—This hospital has recently been enlarged and improved. A special course of instruction is given in ophthalmic and auricular diseases. There are special wards for the treatment of diseases of the eye, of children, and of women, and practical instruction is given on diseases peculiar to women; there is also a separate building for infectious diseases. Clinical clerks to the physicians anddressers are appointed for each of the most deserving of the class. A new operation theatre, sterilising room, and anaesthetic room have been constructed in accordance with modern surgical requirements. A department for minor and light treatment of local injuries has been added. A resident medical officer is elected annually, and resident medical and surgical pupils are appointed from among the past and present students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10 a.m. Special classes for first year students. Full particulars can be had on application to Hon. Sec. Med. Board.

Sir Patrick Dun's Hospital is situated on the south-eastern side of the city, and about a quarter of a mile from the University School of Physic. It is conducted almost exclusively by the professors in that school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but many years ago the obligation was removed, and the hospital is now for surgical and medical pupils. There is a special wing devoted to fever cases, and regular clinical instruction is given by the members of the medical staff throughout the winter and summer sessions. Special classes for students and licensed midwives, connected with the wards, are held all the wards during the months of October, November, and December. They will embrace the elements of medicine and surgery, including note-taking. Opportunities are also afforded to students for examining cases of throat, ear, and eye diseases as well as for performing minor surgical operations and bandaging. In the X-ray Department opportunities are given to the members of the hospital class of seeing the various applications of the X-rays to the diagnosis of disease; and all medical and surgical pupils have been made for practical instruction in anaesthetics. A department for dentistry has lately been added.

Water Miscoridical Hospital, Dublin.—This hospital, at present containing 345 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given by the physicians and surgeons at 9 a.m. daily. A course of clinical instruction on fever is given during the winter and summer sessions. A certificate of attendance upon the meetings of the officers of the licensing bodies, may be obtained. Ophthalmic surgery is taught in the special wards and in the dispensary. Surgical operations are performed on Mondays, Wednesdays, Fridays, and Saturdays at 11 o'clock. Connected with the hospital are extensive dispensaries, which afford valuable opportunities for the study of general surgical diseases and accidents. Instruction is given in pathology and bacteriology. Three house physicians, six house surgeons, and four resident medical and surgical pupils are elected annually. Dressers and clinical clerks are also appointed, and certificates are given to those who perform their duties to the satisfaction of the officers. Lectures are delivered monthly for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the universities and licensing bodies in the United Kingdom. A training school and a home for trained nurses have been opened in connection with the hospital.

Terms of attendance.—Nine months, £12 12s.; six winter months, £8 8s.; three summer months, £5 5s. Entries can be made with any of the physicians or surgeons, except to the Registrars at 1st, 9 and 11 Merrion Square. A prospectus containing in detail the arrangements for clinical instruction, prizes, etc., may be obtained from the Secretary, Medical Board.

Mercer's Hospital.—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the National University School of Medicine, and Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made for the establishment of Cork Street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution. There is a large out-patient department, and a special department for diseases peculiar to women. There are also special wards for the treatment of mental and nervous diseases.

During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A house surgeon is appointed annually. Five resident pupils are appointed, each for six months, and clinical clerks and dressers are appointed monthly from among the most deserving members of the class. The certificates of this hospital are recognised by all the licensing bodies. For further particulars apply to Mr. Seton Pringle, F.R.C.S., 7, Fitzwilliam Place, Dublin.

St. Vincent's Hospital was established in 1834. It has 175 beds, and in connection with it there is a largely attended dispensary, and a nurses' institute. In addition to the ordinary clinical instruction, systematic courses of lectures are given in each of the departments of medicine and surgery, and are illustrated by cases in the hospital. The resident officers consist of two house surgeons, two house physicians and six resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases, and medals and other prizes are awarded at the end of each session. A prospectus can be had from Mr. Kennedy, 68 Merrion Square.

Dr. Steevens' Hospital, situated at Kingsbridge, is one of the oldest and largest clinical hospitals in Dublin, and contains over 200 beds. A new dispensary and out-patient department has been completed and opened to patients. There is accommodation for twelve resident pupils, and six resident physicians, and the special departments, each of whom is supplied with a separate room. All information with regard to these appointments can be had from the Resident Medical Officer at the hospital. Licensing bodies recognise six months' residence as equivalent to a year's ordinary attendance at hospital. The manufactories and railway works in the neighbourhood supply this hospital with large numbers of accidents and other cases, while a special ward for venereal disease affords exceptional opportunities for the study of this important subject.

Jervis Street Hospital is the oldest established in Dublin. The present building was completed in 1896, since which time it has been open for the reception of patients. It includes a large surgical and medical dispensary, and eight new out-patient departments, which is now completed, includes special departments for the treatment of diseases of the skin,
IRELAND—EDUCATION.

SPECIAL HOSPITALS.

The chief of the special hospitals of Dublin are the Rotunda, the Coombe, and the National Lying-In Hospitals, Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Hospital), the Dental Hospital, the Orthopedic Hospital, and the Children's Hospitals in Harcourt Street and Pembroke Road.

The Rotunda Hospital.—This is the largest and the oldest gynaecological and maternity hospital in the British Empire. The work performed by it is about three times greater than that of any other hospital in Ireland. The number of patients admitted to the hospital, and of those attended in the external maternity has increased enormously within recent years. The routine daily work comprises the attendance on lectures on midwifery and gynaecology; practice in gynaecological palpation; personal conduct of a parturient in both the external and the internal maternities; cystoscopic examinations; and attendance at the operative work of the hospital, in which the students assist. The hospital affords exceptional advantages to qualified students, and all women (with the considered competence) are permitted a certain amount of practical operative work—viz., use of forceps, curettings, perineorrhaphy, etc. A special afternoon class in gynaecology is held by the Senior Assistant, and one in special pathology by the Pathologist. Fee for each £2 2s. per month. The pathological laboratory has been an important feature of the hospital. Students can enter at any time for periods of six months or longer. They have the opportunity of attending at the hospital and seeing all the licensing bodies. The L.M. certificate is obtained by attendance at the hospital for six months, with the subsequent passing of an examination. A special certificate in gynaecology is presented to students who have the Master's approval. Paid clinical assistants are selected (from amongst those who have obtained the hospital L.M. certificate), for periods of six months. Women students can also reside in the hospital under conditions similar to men. The grounds of the hospital contain courts for lawn tennis and croquet, and a skating rink. The entire students' quarters have been rebuilt and refurnished, with electric light, new bath-rooms, reading-room, new billiard table, etc. Fees: £1 13s. 6d. per month, £2 9s. for six months, £3 18s. for twelve months, £4 12s. six months, £4 1s. single months other than the first, £4 4s.; board and lodging in the house per week £1 18s. Night students (not residing in house), £6 18s. for six months; £4 18s. for the third and fourth months. For further particulars apply to the Master, Dr. Henry Jellett, Rotunda Hospital, Dublin.

Coombe Lying-in Hospital.—This hospital, which devotes itself to the care of lying-in women, and to the treatment of diseases peculiar to women, was founded in 1824. The original hospital was a four-storeyed building erected in 1825. An up-to-date labour theatre and waiting ward were added in 1904. The new Gynaecological Hospital was finished in 1903. It contains two modern operating theatres. The former Gynaecological Hospital has been converted into sleeping rooms for resident pupils.

The Pembroke Dispensary was opened in 1911. The hospital is situated centrally in a very densely populated district. In addition to a very large gynaecological out-patient service, operations are delivered annually. The Master visits the maternity wards daily with the students at 9.30 a.m. This is followed by a lecture on midwifery. At 11 a.m. the gynaecological wards are visited; followed by this a lecture on gynaecology, physiology, and practical operations performed in the theatres. At 4 p.m. on Mondays, Wednesdays, and Fridays, the Master conducts a special class in practical obstetrics, including palpation, auscultation, palpation, pathology, and operations on the phantom. Lady medical students can reside in the hospital and take their ordinary housekeeper, Board and lodgings, £1 1s. per week. The students' quarters are comfortably furnished.

Fees.—External pupils (for full course of six months), £3 8s. This includes one month's residence in hospital. Intern pupils—first and second month, £4 4s.; each consecutive month, £3 3s.; six months and L.M. diploma, £18 18s. Board and lodging in the hospital, 18s. per week. Lady students, inter—first month, £5 5s.; each consecutive month, £4 4s.; six months and L.M. diploma, £18 18s. There is no extra charge for attendance at any of the dispensaries. Certificates of attendance from this hospital are accepted by all the licensing bodies.

The National Children's Hospital for the treat- ment of all non-infectious diseases peculiar to children, with which the Pitt Street Children's Hospital, founded in 1821, was amalgamated, contains 45 beds for the reception of cases of deformity and all other forms of surgical disease. There is a general dispensary for external patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Sir Lambert H. Oomsley, M.D., The National Children's Hospital, Temple Street, Dublin (under the care of the Sisters of Charity).—This institution is the largest children's hospital in Ireland. There are 100 beds available for patients; about 1,000 cases are admitted to the wards annually; and about 7,000 or 8,000 seen in the dispensary. The operating theatre has recently been opened. It is fitted and furnished in the best possible fashion for present-day surgery. Special attention is given to orthopaedic surgery.

The hospital is recognised for clinical instruction in the diseases of children by those licensing bodies which require a certificate of instruction in this important branch of medical education. A nursing home is in connection with the institution, and trained nurses are always available for private cases. Senior students or others requiring a post-graduate course at the hospital.
IRELAND—

The hospital should apply for full particulars to Dr. M. C. Stanton, hon. sec., or to any member of the staff.

THE INCORPORATED ORTHOPEDIC HOSPITAL, IRELAND.—This hospital was founded in 1876, and contains 50 beds, exclusive of every chair of deformity. Particulars may be obtained from the Secretary, at the Hospital.

The Royal Victoria Eye and Ear Hospital, Adelaide Road.—This hospital, which was opened in the early part of the last century, contains, the Maternity Hospital, the National Eye and the National Eye and Ear Infirmary. The hospital contains 100 beds. Clinical instruction in diseases of the eye and ear, including the use of the opthalmoscope and operations, is given daily from 10 till 1. Special classes for practitioners are arranged, and for the demonstration of cases, are formed from time to time.

The Incorporated Dental Hospital, Lincoln Place.—This hospital is the only special dental hospital in Ireland. It is officered by a strong staff of the dental surgeons of Dublin, and has a large clientele and extensive practice among the Dublin poor. The fees are $2.12.5., for each year's Dental Hospital practice, and proportionately smaller fees for shorter periods and for students. The term of payment in dental mechanics required by the various licensing bodies may be taken in the recently enlarged Hospital Laboratory.

Particulars may be obtained from the Dean.

DEPARTMENT OF DISEASES OF THE SKIN AND CANCER, Holles Street.—Senior students are admitted free to the practice of this hospital, which has a large out-patient attendance, with 15 beds for intern cases. Classes of instruction will be given at regular intervals during the winter and summer sessions in the use of the Finsen light, X-rays, high frequency currents and radium, with demonstrations on (1) the production and use of the Röntgen rays, (2) electric currents, direct and alternating, with description of resistances, rectifiers and transformers; (3) accumulators, their construction, use, and methods in charging; (4) vacuum tube, choice of tube for particular kinds of work; fluorescent screen, and how to localise foreign bodies.

BELFAST HOSPITALS.

Royal Victoria Hospital.—Established 1764; incorporated by Royal Charter, 1875 and 1893. New hospital opened, September 17th, 1903, 300 beds; Convalescent hospital, 22 beds; Children's Hospital, 83 beds; Consumptive Hospital, 10 beds. Clinical instruction in medicine and surgery is given each morning by the staff. "

Mater Infirmorum Hospital.—Established 1833. 160 beds. The New Mater Hospital, which was erected at a cost of over $50,000, was formally opened on April 23rd, 1900. During the year the intern patients numbered 1,225; accidents, 1,270; and cases treated in the Dispensary, 22,557; 380 surgical operations were performed. The total number of patients who received treatment was 27,884, being an increase of 1,417 as compared with the year 1904. A notable feature is in the number of accident cases, as the hospital is conveniently situated in proximity to a large working-class population, and within easy reach of most of the public works.

The Belfast Maternity Hospital (Incorporated).—Established 1864. 30 beds.—The practice of the Maternity Hospital, the certificate of which is recognised by all the universities and colleges, &c., is open to students. The fee for the session is $2.2.5. Resident nurses are also received for training for a period of six months, and a diploma given which is recognised by public authorities. A course in the use of the opthalmoscope and the treatment of cases is arranged in the Central Medical Board. Conditions for such an application to the Matron. During the year 1911, 567 patients were treated in the hospital, and 556 patients at their own homes. Besides this, 1,867 patients were treated in the infirmary or special ward. Clinical lectures and bedside demonstrations are given by members of the staff during both the winter and summer sessions. Students wishing to attend should apply to Dr. H. D. Osborne, 32 Lonsdale Terrace, Belfast, Hon. Secretary to Medical Staff.

Note.—Hospital was rebuilt in 1904 and removed to new premises in Townsend Street. A Resident Surgeon is elected periodically.

Ulster Eye, Ear, and Throat Hospital.—Established 1871. New hospital opened 1874, 30 beds.

CORK HOSPITALS.

National Charitable Infirmary.—Established 1774; 110 beds. Special wards for treatment of diseases of women and children. The external department is largely made use of, and the number of accidents treated is very large. Clinical instruction is given daily from 9.30 a.m. to 12 noon. An operating theatre has recently been added at considerable expense.

Cork South Infirmary and County Hospital.—Founded 1773. The hospital contains 100 beds, available for clinical instruction, and is divided into two surgical wards devoted to the treatment of diseases peculiar to women and children, and a large medical and surgical external department. Clinical instruction is given daily during the session.
IRELAND—EDUCATION.

The Medical Press. 283.

from 9.30 to 11.30, in both the medical and surgical wards, and clinical lectures are regularly given. Stomachs are properly examined in the methods of using the rays by practical demonstration on the cases requiring their use.

For further particulars apply to Norman J. Townsend, hoii, sec.

VICTORIA HOSPITAL FOR WOMEN AND CHILDREN.—
Established 1874. 70 beds. A large amount of work is done in this hospital to relieve the poor of Cork, Kerry, and other counties.

* COUNTY AND CITY OF CORK LIVING-IN HOSPITAL.—
Established 1795.

* EYE, EAR, AND THROAT HOSPITAL, Western Road.—
Incorporated 1898. 22 beds. In-patients treated during year, 454; out-patients, 4,218. Clinical Instruction is given during college hours. Special demonstrations in the use of the ophthalmoscope, laryngoscope, &c., are given from time to time.

* FEVER HOSPITAL AND HOUSE OF RECOVERY.—
Established 1804. 110 beds.

* MATRIMONY.—Established 1872.

* MERCY HOSPITAL.—Established 1857. 80 beds.

* GALWAY HOSPITAL.—

* COUNTY HOSPITAL.—Established 1786. 60 beds.

* No answer to our request for information received from these hospitals.

IRISH PUBLIC SERVICES.

The Poor-Law Medical Service.

For several years past the unsatisfactory nature of the Irish Poor Law Medical Service, as a career for young practitioners, has been evident. In addition to the petty annoyances, the laborious and harassing duties, and the ever-increasing amount of clinical work which the new orders of the Local Government Board impose from time to time, the medical officers are underpaid, their salaries being totally out of proportion to the duties discharged, and in the majority of rural districts barely sufficient to cover the out-of-pocket expenses, such as are incurred in the keeping of a horse and man, and other servants. The low pay is the poor law medical officer bound to the discharge of his duties that unless incapacitated by sickness or other cause, or with the permission of the guardians expressly granted, he cannot leave his district for a single day, even if he makes provision for the performance of his duties in his absence by a brother practitioner. It is right to point out to young practitioners the following facts: (1) That the Poor Law Medical Service is one in which there is no promotion. (2) That it is a service where few facilities exist for originating, and still less for furthering medical culture, especially in the rural districts. (3) That, while medical education has become wider in its requirements and more costly and difficult to procure, almost the same rate of payment as was given to less educated men forty years ago is still offered, and this, too, at a time when lucrative private practice is more difficult to obtain. (4) That there is no compulsory superannuation, and, as a consequence, many old and infirm men are forced to remain in the service long after they have rendered some years of his to discharge the duties, second class, and in the face of extreme poverty and perhaps the workhouse itself staring them in the face.

There are about 160 workhouse and about 80 poor law medical officers. The salary is said to average about £14.

The dispensary medical officer is also ipso facto the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act, passed in 1873 and amended in 1878. The former office, in country districts, yields between 22s. 6d. and £10 a year, and the enrolls of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who applies. He is paid, during long vacations, his salary, by the guardians, and the sum total of these fees varies, according to the population of the district, from £1 to £100, an average for the provinces being about £60.

Qualifications.—The qualifications required by the Local Government Board are a licence in surgery, in medicine, and in midwifery; but registration in the "Medical Register," if effected since the passing of the Medical Act, in 1866, fulfils all requirements. Candidates must be 21 years of age. Candidates recently qualified must possess a certificate of competence in vaccination.

Duties.—The duty of the dispensary doctor is twofold. He has to attend his dispensary or dispensaries on a given day, and visit in the course of the day or night sick persons for whose relief a visiting ticket has been issued and to continue his attendance as often as may be necessary to the termination of the case. Moreover, he has many books to keep and a multitude of returns to make, and in most districts he has to make up all the medicines for the poor.

Workhouse Hospitals.—The number of unions in Ireland is 150, to each of which is attached one or more medical officers, appointed and controlled by the board of superintendents in five or six years' service as the dispensary medical officer. The salary is about the same as that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily workhouse business and no night visits out of doors or long journeys across the country are involved.

The Irish Lunacy Service.

This service, at present, affords a comfortable livelihood for 22 resident medical superintendents and 32 assistants. The superintendent receives salaries and allowances ranging, according to the number of inmates of the asylum, from £500 to £1,000 a year, and the assistant, from £300 to £500 a year, salaries and emoluments averaging about £200 to £300 a year. There are also a few visiting physicians receiving about £120 a year, but this class of officer is being allowed to die out, and no new appointments will be made. The medical superintendents and assistants must devote their whole time to their duties.

The appointments of medical superintendents are in the hands of the asylum committee, with the proviso that no one shall be appointed who is not a registered medical practitioner in five years' service as assistant. The assistant is also appointed by the committee. In addition to these officers, there are, in certain larger asylums, clinical residents, who receive about £50 a year and full allowances. These appointments afford excellent introduction to the higher places in the service.

Tuberculosis Service.

Most of the county and county borough councils are proceeding to appoint tuberculosis officers to carry out work under the Tuberculosis Prevention Act (1908) and the National Insurance Act (1911). The duties proposed are usually (1) to act as superintendent of the county sanatorium; (2) to conduct one or more tuberculosis dispensaries; (3) to act as consultant with practitioners in regard to tuberculosis patients; (4) to conduct a bacteriological laboratory; (5) to act as adviser to the local insurance committee and the county council on tuberculosis; (6) to organise and conduct anti-tuberculosis work generally in the county or county borough. The tuberculosis officers must give their whole time to their duties. The salaries vary from £500 to £900 a year, with an allowance for expenses. The lower figure must be regarded as quite inadequate, and candidates before applying for such posts should satisfy themselves that the conditions of service have been approved by the local medical profession.

National Insurance Work.

The National Insurance Act (1911) has provided a certain amount of employment for medical men. As the question of extending the medical benefit of the Act to Ireland is still under discussion, all present arrangements are of a purely temporary character. The conditions of many of the appointments made by the Insurance Commissioners are contrary to profes-
In Scotland medical education is centred round the four Universities. It is very much a matter of convenience, or of fancy, which University the student seeks. Naturally, to those with no local ties, the Edinburgh degree proves attractive, and the number of graduates from overseas who have chosen Edinburgh University is doubtless growing. It is plain that to the University degrees, one other qualification to practise can be obtained in Scotland—the joint licence of the Royal College of Physicians, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow. The standard of examination for the triple qualification (as it is called), though lower than that of the Universities, is yet high enough to test the abilities of the candidates, if one may judge from the number of rejections. The standard, too, is being gradually raised. Of late years there has been a falling off in the number of candidates for the triple qualification, and the majority are not Edinburgh-trained students, but hail from other schools.

The diminution of the number of Scottish students is generally ascribed to the operations of the Carnegie benefaction enabling men who formerly would have been unable to do so, to take the University degree. One candidate for Scottish medical schools is the existence, side by side with the University, of extra-mural schools, independent in every respect of the University, and recognised by the latter as schools whose classes qualify for graduation. Both the extra-mural and the University system, just as the triple qualification has, from the Carnegie bequest, and there is reason to believe that under modern conditions it is unlikely to occupy such a prominent place in the future as in the past. The proposed introduction by the Universities of a composition fee for the medical curriculum is viewed by the extra-mural lecturers with dislike, because it is feared that if it comes into effect the number of extra-mural students will again decline.

It must be allowed that the tendency towards concentration of teaching under the University is stronger than in the past. The increased cost of equipment for teaching, in particular, renders it impossible for an unendowed school to compete with a University. This applies especially to the preliminary and purely scientific subjects of the curriculum up to and including physiology and pathology. It is doubtful whether it will be possible for such subjects be adequately taught by private individuals who have to depend largely or wholly on class fees for their remuneration.

During the last few years the medical curriculum has been modified by a revision of the system that has undergone, and is still undergoing, great changes for the better. An agreement has been entered into by the managers of the Infrmary and the University of Edinburgh, under which the facilities for clinical teaching, and for pathology, are much enhanced. The new arrangements for teaching the special subjects (all of which are now compulsory) will undoubtedly make for efficiency, by distributing the students and preventing overcrowding. It may now be said that the education given in the Scottish schools generally has no need to fear comparisons. The dispensary system is peculiar to Scotland; what we have is a dispensary system open to the public in the English sense of the word. A dispensary is an out-patient clinic, separate from any hospital, staffed by honorary medical officers, and attended for instruction by students. Not the least important part of the student's curriculum is the instruction in practical medicine which outdoor patients in their own homes under the same conditions as obtain in practice among the lower working classes, University students have the privilege of working under extra- as well as intra-mural teachers, with whom they are engaged full time are limited to the latter. It is not uncommon, however, for a man to come up intending to take the licence, and to change his mind and go in for a degree, or vice versa, and this can usually be done.
without much trouble or added expense, provided the change is made early in the course. The main problem in the Edinburgh curriculum, and many students are in the habit of going
to Dublin or Glasgow for their practical midwifery.
When all is said and done, however, the Scottish graduate or diplomate receives an excellent training in his profession, and his course is long enough in theoretical subjects, is
defective in practical work. It is impossible to make any
very definite statement as to the relative cost of a
medical education in the different institutions, as costs are
so much dependant on personal circumstances, but a rough
estimate will be made. The Carnegie Trust has fixed the
minimum fee for the M.B. degree at £146; but almost
every student finds it practically necessary to attend
additional classes.

POST GRADUATE TEACHING.
In Edinburgh, past graduate classes covering prac-
tically the whole field of medicine take place annually
from the middle of July to the end of September.
Particulars may be obtained from the Secretary, Post-
Graduate Courses in Medicine, University New Build-
ing. In Glasgow there are also post graduate classes
in connection with the Western and Royal Infirmarys.
During the spring of this year a committee was
appointed, on the recommendation of Professor Paton,
Bird, to investigate the possibilities of spreading the
influence of the International Board for Post Graduate Instruction in Berlin, to consider
the opportunities of developing this side of medical work
in Glasgow, but its labours have not yet been pro-
ductive of any change in this year.

THE CARNEGIE TRUST.
Under the Carnegie Trust payment is now made
of the whole or part of the ordinary class fees exigible by the Universities from students
of Scottish birth or extraction, and of six
years of age or over, who are domiciled in Scotland.
An Education scholarship, after the age of fourteen years, at
State-aided schools in Scotland, or at other schools and
institutions in Scotland as are under the inspection
of the Scottish Education Department.

The Trust provides for the payment of the class fees
of the above students proceeding to graduation in medi-
cine or science. Application for payment of class fees
under the conditions of the Trust should be made to the
Secretary, Sir William S. McCormick, Merchants' Hall,
Edinburgh.

UNIVERSITY OF EDINBURGH.
Four degrees in medicine are granted; Bachelor of
Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor
of Medicine (M.D.), and Master of Surgery (Ch.M.).
The first two must be taken together, the last two may
be taken separately.
These are additively to the degrees of Bachelor of
Medicine and Bachelor of Surgery who has not
been engaged in medical study for five years
after passing a preliminary examination in general
knowledge in accordance with the medical ordinances.
A degree in Arts or Science of a British or other recon-
ised University is held to supersede such preliminary
examination. The subjects included in this general
examination are English, Latin, elementary mathe-
matics, and Greek, or French, or German.
The preliminary examination is open on October 1st and extends to not less than 30 teaching weeks,
divided into three terms. Two terms are equivalent to
one winter session, and one term to one summer
session. Two years of the five must be spent at the
University, the remaining three years at any other
Medical School recognised by the University
Court.
During each of the 12 terms preceding the fifth or
final year the student must have attended one of
more practical classes on the subject of the curriculum.
He must attend chemistry during two terms, practical
chemistry, botany, zoology, physics, forensic medicine,
and public health during the term, anatomy during
two terms, pathology and physiology, each three terms,
midwifery, medicine, and surgery during two terms
each. He must attend a course of twenty-five lectures
practical pharmacy, or have dispensed drugs for a period
of three months in a recognised hospital or dispensary.
He must attend a nine months' course in clinical
medicine and in clinical surgery. During the fifth or
final year he must be engaged in clinical practice for at
least nine months. In all, before graduation, he must
have done hospital work for at least three years, and
have acted as clerk in the medical and surgical wards
and attended for six months the practice of a dis-
patch officer or any other physician. He must have
studied operative surgery, mental diseases
post-mortem, fevers, diseases of the eye, diseases
of children, of the ear, nose and throat, and of the
skin, vaccination, practical anesthetics.
He must also have at least one year of labour
under the superintendence of a registered medical
practitioner, and 12 such cases, and, for at least three
months, the practice of a midwifery hospital.
Each candidate is examined both in writing and
oral work.

1. On zoology, botany, physics and chemistry.
2. On anatomy and physiology.
3. On pathology and materia medica and ther-
  apy.
4. On medicine, surgery, midwifery, forensic medi-
  cine, and public health.
The examination of candidates beginning in winter
is held in the following terms: for the degrees of
Bachelor of Medicine and Bachelor of Surgery, who is of
the age of twenty-four years, or who has passed a certicate of having been
engaged in medical practice or in the medical
services, or for two years in practice other than
purely medical. For the degree of Doctor of Medicine or Bachelor of
Surgery, who is of the age of twenty-four years, and who has
been engaged in medical practice or in the medical
services, or for two years in practice other than
purely medical. The candidate shall submit to the Faculty of
Medicine, in addition to any branch of knowledge com-
prised in the professional examinations for the degrees
of Bachelor of Medicine and Bachelor of Surgery. The
candidate will also be examined in clinical medicine and
must show practical acquaintance with advanced
methods of diagnosis; he must have examined mental
and nervous diseases of children under the superintendence of those who did
not pass in these subjects with the rest of their
preliminary examinations.
The regulations for the degree of Ch.M. are very
similar.

FEES.—The fee to be paid for the degrees of Bachelor
of Medicine and Bachelor of Surgery is twenty-two
guineas. The fee for the degree of Doctor of Medicine
or of Master of Surgery is ten guineas (Old Regula-
tions, 4s 6d.).
The total expense of the curriculum, including
examination and matriculation fees, is about 190.

Among scholarships, &c., open for competition during
the session 1914-15, are the following:—Vans
Dunlop scholarships value £100; Buchanan scholar-
ship in midwifery, value £25; Monat scholarship

285 SCOTLAND—EDUCATION. THE MEDICAL PRESS.
in practice of physic. £27: Allan Fellowship in clinical medicine and surgery, £35. There are also a great many other bursaries, fellowships and prizes open during the session of 1913-14 and for the details governing entry for these the University Calendar (James Thin, South Bridge, Edinburgh) should be referred.

Graduation in Public Health.—Degrees (B.Sc. and D.Sc.) are also conferred in Public Health. Candidates must be graduates in medicine and must matriculate for the year in which they proceed for examination. They must (1) have passed at least twenty hours a week during a period of eight months in a recognised Public Health laboratory—five of these months must be spent consecutively in the Public Health Laboratory of the University of Edinburgh (Tusher Institute); and (2) have attended a course of lectures on hygiene, in addition to that qualifying for graduation in medicine, and one on geology.

Candidates for the second examination are not admitted until eighteen months have elapsed after having passed M.B., Ch.B., or sooner than six months after the first examination. They must have attended two courses of Public Health, one dealing with medicine, the other with engineering in relation to public health. They must also have studied practical sanitary work under a Medical Officer of Health and have spent not less than one month in a fever hospital, and three months' instruction in mensuration and drawing.

Fees for Science Degrees: B.Sc., first examination, £3 18s.; B.Sc., second examination, £3 3s.

Diploma in Tropical Medicine.—The University Diploma in Tropical Medicine and Hygiene is conferred on graduates of the university, and on registered practitioners who have resided abroad and who receive permission of the Senate to become candidates for the diploma. The course includes practical bacteriology, tropical diseases and hygiene, the zoological character and history of disease-carrying insects and venomous animals, clinical instruction at an hospital for tropical diseases. The examination is held in December and June, the fee being £1 4s. A special certificate in Tropical Diseases is also granted under less stringent regulations, and after a shorter course.

Degree in Psychiatry.—The course extends over one year, during which candidates must attend classes on (1) Anatomy and (2) Physiology of nervous system; (3) Pathology; (4) Bacteriology in relation to nervous system; (5) Pathology of the Nervous System; (6) Neurology; (7) Psychiatry. There are two examinations, one on anatomy, physiology, pathology and bacteriology, the second on the remaining subjects. The fees amount to about thirty-seven guineas.

University Hall, Edinburgh.—In Edinburgh there are numerous halls of residence for under-graduates. In each house there are private studies with or without bedrooms, and common sitting and dining rooms. The charges are moderate. It is a satisfactory indication that in University Hall that many graduates live in it and are willing to help or coach the undergraduates for moderate fees. To gain admission two references must be produced from past or present residents, or other suitable person. Those are concerned have also voted on a house meeting, and any unruly member may be expelled by a similar meeting of the residents.

Medical School for Women.—Classes for women are now held at the College of Surgeons and the New School for Women, which were opened by the University. The First Inaugural Address was delivered on 5th November, 1913, by the M.P. for the City of Edinburgh South. The Medical School for Women was presented with a gold cup by the University to give lunches to its bedside classes.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and an examining body, but admits to examination only those candidates whose degree courses are approved by the University. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers; but not less than one half of the subjects other than clinical must be taken in this University. The candidates have to register with the University or College, and at least two years of the course must be taken in Glasgow University. Four degrees, open both to men and to women, are conferred—M.B. and Ch.B. (always conjointly), M.D. and Ch.M.—and the necessary preliminary examinations are passed in (1) English, (2) Latin, (3) Mathematics, and (4) an Additional Language, namely, Greek, French, German, Italian, or another approved language, with possible options to students whose native tongue is not English, and, on passing, students must register in the books of the General Medical Council. For M.B. and Ch.B. a curriculum of five years is required. A syllabus with full details of the curriculum and of the preliminary examination may be had, post free, on application to the Register.

Fees for the M.B. and Ch.B. are £23 2s.; for M.D. £15 15s., and for Ch.M. £15 15s. For hospital attendance there is an initial fee of £10 10s., with a further fee of £2 2s. for each winter session, and £1 1s. for each summer session, and an examination fee of £5. There are very extensive general hospitals in the city, which afford exceptional opportunities for clinical work, while the Royal and other asylums, the City Fever Hospitals, the Maternity Hospital, the Sick Children's Hospital, the Royal Infirmary, &c., give facilities for the study of special branches.

The degrees of B.Sc. and D.Sc. in Public Health and of B.Sc. in Pharmacy, are also now conferred. But the University has made considerable efforts to extend the facilities for laboratory accommodation and equipment, to augment its teaching staff, and to encourage postgraduate and research work. Within recent years there have been provided new laboratories in the departments of pathology, anatomy (costing £13,000), chemistry, and surgery (costing £9,000), while new laboratories, costing, with equipment, upwards of £50,000, have been erected for the departments of physiology, materia medica, and medical jurisprudence and public health.

Bursaries and prizes to the annual amount of about £2,000 are annually awarded by the Royal Infirmary, including an Arthur bursary for women, £30 for three years.

Several bursaries open to students in any faculty are not infrequently held by medical students, and Scholarships and Fellowships to the annual amount of £1,500 may be obtained by medical students who have gone through the Arts course.

Queen Margaret College for Women.—Founded in 1883 by the Glasgow Association for the Higher Education of Women, which was formed in 1877 with the object of bringing University instruction, or its equivalent, within the reach of women, Queen Margaret College in 1893 added its faculty of Arts a School of Medicine for Women. This was organised entirely on University lines, and with the view of preparing for University degrees and competent candidates for the Ordinance of the University Commissioners authorising the Scottish Universities to admit women to instruction and graduation, Queen Margaret College became the Women's Department of the University of Glasgow, its classes in medicine taken for the M.A., in conjunction with the University were recognised as qualifying for the degree. A full course of study for M.B. and Ch.B. is given by University professors and lecturers, with excellent facilities for hospital and dispensary work and for private practice. A Hall of Residence for the students was founded in 1894. Fees for the classes at Queen Margaret College may be paid by the Carnegie Trustees; and several bursaries are open to women students of medicine.

The Winter Session begins on 11th October. The
prospective can be obtained from the Ministry of Education, Government of Scotland.

UNIVERSITY OF ABERDEEN

The University of Aberdeen possesses under the charter the highest privileges granted to any educational institution. It confers degrees in the three faculties of Arts, Science, Divinity, and Medicine. It also grants degrees in civil and mining engineering and in agriculture. The university, moreover, is provided with two lecture halls in the three faculties of arts and surgery. The more the professors devote their time to the teaching of their own subjects the more they are enabled to give their attention to the study of modern science and technology, which has recently acquired considerable importance. The degree of M.B. is conferred by the university, but in separate exercises. The examinations in physical and moral science, as well as in the College of Science, are held separately, and the medical and surgical examinations are also separate. The degree of M.B. must be obtained by all candidates for the degree of M.D. at the same time.

University of Edinburgh.

The University of Edinburgh is one of the oldest universities in Scotland, and is the most important centre of education in the country. It confers degrees in arts, medicine, law, and science. The university is provided with a medical school and a college of medicine, and the medical examinations are held separately. The degree of M.B. must be obtained by all candidates for the degree of M.D. at the same time.

University of St. Andrews.

The University of St. Andrews is one of the oldest universities in Scotland, and is the most important centre of education in the country. It confers degrees in arts, medicine, law, and science. The university is provided with a medical school and a college of medicine, and the medical examinations are held separately. The degree of M.B. must be obtained by all candidates for the degree of M.D. at the same time.

University of Glasgow.

The University of Glasgow is one of the oldest universities in Scotland, and is the most important centre of education in the country. It confers degrees in arts, medicine, law, and science. The university is provided with a medical school and a college of medicine, and the medical examinations are held separately. The degree of M.B. must be obtained by all candidates for the degree of M.D. at the same time.
treatment. Six resident qualified assistants and an outdoor obstetric assistant are appointed annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed to assist in the post-mortem room. The instruction given at the said College is comprised of practical instruction given by the Scotch Universities, the University of London, the University of Cambridge, the Royal University of Ireland, and by the Royal Colleges of England and Scotland. Hospital tickets for the infirmary, £2 2s. each session, or £1 1s. a year. Perpetual, £10 10s. in one payment, or £10 10s. by instalments.

Further information will be found in the Calendar of the University published by Messrs. Blackwood and Sons, Edinburgh, the "Scotch Calendar," published by the Royal College of Physicians and Surgeons of Glasgow, and the "Royal College of Physicians and Surgeons of Scotland." The examination can be had from the Dean of the Medical Faculty, Professor J. A. Kynoch.

THE COLLEGES.
The Royal Colleges of Physicians and of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow have arrangements by which the student may obtain the diploma of the co-operating body, and can register three diplomas under the Medical Acts—viz., Licentiate of the Royal College of Physicians of Edinburgh, Licentiate of the Royal College of Surgeons of Edinburgh, and Licentiate of the Royal Faculty of Physicians and Surgeons of Glasgow.

The three bodies grant their single qualifications only to candidates who are already registered as possessing another and opposite qualification in medicine and surgery as the case may be.

REGULATIONS OF THE CONJOINT BOARD OF THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—The candidate must produce certificates of having attended the following course of lectures, the certificate distinguishing the sessions and the months in which the courses were attended, Anatomy, six months; practical anatomy, twelve months; chemistry, six months; practical chemistry, three months; materia medica, three months: physiology, six months; medicine, six months; clinical medicine, nine months; surgery, six months; clinical surgery, nine months; midwifery, three months; medical jurisprudence, three months; pathology, three months. The candidate must also produce the following certificates:—(a) Of having attended six cases of labour under the guidance of a full-qualified practitioner; (b) Of having attended for three months instruction in practical pharmacy. The teacher must be a member of the Pharmaceutical Society of Great Britain, or the Superintendent of a laboratory of a public hospital or of a hospital for a fee of £5. (c) Of having attended for twenty-four months the medical and surgical practice of a hospital, containing eighty patients, and possessing distinct staffs of physicians and surgeons, and of having assisted for six months the practice of a public dispensary, or of having assisted for six months the practice of a registered practitioner. (e) Of having been instructed in vaccination.

First Examination, Fee £5.—The First examination shall embrace chemistry, physiology, and elementary botany, and shall not take place sooner than the end of the first year, including a winter and summer session. Candidates who desire to enter for the first professional examination must produce certificates of attendance on chemistry, practical chemistry, anatomy, and physiology, for the following three years.

Second Examination, Fee £5.—The Second examination embraces anatomy and physiology and shall not take place before the termination of the summer session of the second year of study. Candidates must produce certificates of attendance on anatomy, practical anatomy, and physiology.

Third Examination, Fee £5.—Comprises the subjects of pathology, materia medica, and pharmacology and advanced anatomy.

Final Examination, Fee £15.—The Final examination embraces medicine (including therapeutics and medical anatomy, clinical medicine); surgery (including surgical anatomy and surgical pathology); clinical surgery; midwifery and gynecology, medical jurisprudence, and forensic medicine, and shall not take place before the termination of the full period of study.

Subjects of Preliminary Education: (1) English grammar and composition; (2) Latin, grammar, translation from specious authors and easy unseen translation; (3) arithmetic, fractions; (4) algebra, to simple equations; (5) geometry, to the first two books of Euclid; (6) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics; (7) one of the following—Greek, Hebrew, Latin; (8) any other modern language; (9) logic; (10) botany; (11) zoology; (12) elementary chemistry. Qualification in Public Health.—The College of Physicians, in association with the Royal College of Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, confers a certificate of competency in public health. The examinations are held in April and October. Fee £10 10s. For the special regulations of the Royal College of Surgeons of Edinburgh, intending candidates should apply to Dr. James Robertson, 48 George Square, Edinburgh, and for those of the Royal College of Physicians, to the Secretary.

The Fellowship of the Royal College of Physicians of Edinburgh is conferred only by election, and the candidate must have been a candidate for at least three years, and have attained the age of twenty-seven years.

The Membership is conferred only on a licentiate of a college of physicians of graduate in medicine of a British University, or on one who has obtained his degree in a University in the United Kingdom, and has attained the age of twenty-four years and shall have passed an examination on: (1) medicine including therapeutics; (2) one of the following optional subjects, in which a high standard of proficiency is expected:—(a) a department of practical pharmacy; (b) a department of clinical medicine; (c) pathology; (d) medical jurisprudence; (e) public health; (f) midwifery; (g) gynecology. The examination is of a searching character.

The fee for membership is £35 guineas, for fellowship £38 guineas, with a stamp duty of £2 10s. 10d. in all.

The licence, or single qualification in medicine, is conferred on candidates who already possess a recognised qualification in surgery. The examinations for this licence are held on the first Wednesday of each month, and are conducted by the Secretary, in medicine, materia medica, midwifery and medical jurisprudence. The fee is £15 15s., and intending candidates should communicate with the Secretary of the College at least eight days before the date of examination.

The Fellowship of the Royal College of Surgeons of Edinburgh is conferred (except under certain conditions) as to age and professional standing only on candidates who have passed a special examination, and have previously obtained a diploma from the college, or from either of the Royal Colleges of Surgeons of England, or the Royal Faculty of Physicians and Surgeons of Glasgow, or the surgical degrees of the Universities of Great Britain, and who are twenty-five years of age. The subjects for examination for those who are already Licentiates of the College and are registered in practical surgery, clinical and operative surgery and, one optional subject.

Those who are not Licentiates of this College: on principles and practice of surgery, clinical and operative surgery, surgical anatomy, and one optional subject; and in such supplementary subjects as have not, in an adequate manner, been included in the examination for the registrable surgical qualification possessed by such candidates, and which are required in the examination for Licentiates of this College.

The subjects diversely embraced embrace: (a) Surgery, special branches; (b) advanced anatomy and physiology; (c) surgical pathology and morbid anatomy; (d) midwifery and gynecological medicine and surgery; (e) medical jurisprudence and surgery; (f) practice of medicine and therapeutics. The examina-
tions are written, oral, and practical. Three weeks' notice must be given to Mr. James Robertson, from whom full particulars as to certificates required may be obtained. The following qualifications are all the diploma of Licentiate of the College, and £42 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, who have been in practice for not less than ten years, and who have highly distinguished themselves or who have highly distinguished themselves in any branch of practice, may under special circumstances be elected without examination. Women are not admitted to the Fellowship of either college.

Licence.—The examination embraces the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and shall not take place before the termination of the full period of study. Fee, £15 13s.

DENTAL DIPLOMA.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a University, or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. The fee is £10 0s.

Edinburgh Royal Infirmary.—Clinical instruction is afforded at this institution, which contains 900 beds under the supervision of professors of the University and the ordinary physicians and surgeons of the Infirmary. Special instruction is given on diseases of women, including venereal diseases, and diseases of the eye, ear, and skin, in addition to the large and varied number of ordinary medical and surgical cases which in a great industrial centre daily require attention. Students at the college and hospital get the benefit of dispensary experience free of charge, and also better professional discipline and receiving clinical experience can be found than in the Glasgow Royal Infirmary. Clinical instruction in midwifery is given in the new Maternity Hospital by Prof. Jardine.

The appointments are as follows:—
1. Resident physicians and surgeons are appointed and live in the house free of charge. There is no salary. The appointment is for six months. These appointments may be renewed.
2. Non-resident physicians and surgeons (in the special subjects and for out-patient work) are appointed for six months. These appointments are renewed.
3. Clerks and dressers are appointed by the surgeons and are paid a salary of 15s. per month. No fees are payable for any surgical or medical appointment.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

The government of this school, established in 1595, is now vested in a board which is equally representative of the two Royal Colleges and the Lecturers, the school being styled The School of Medicine of the Royal Colleges, Edinburgh. The lecturers deliver qualifying courses of instruction of the same duration and scope as those delivered within the University, while a large number of non-qualifying courses on special subjects of interest to medical practitioners are also delivered both in the winter and summer sessions. The students who attend the classes of the School of Medicine are largely students proceeding to the University degree, as well as those who are intending to take other degrees in the University, and such as are able to take the examinations for the degrees of the College. An application to the Dean of the School, 21 Bristo Place, Edinburgh.

The minimum cost of the education in the School of Medicine for the triple qualification of physician and surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, including the fees for the joint title, being termed known as the Glasgow Royal Infirmary School of Medicine. The Medical Faculty occupies buildings erected for the purpose of the medical school in the grounds of the hospital. The college is equipped with complete electric light apparatus and a beautiful electromedical lantern. Attendance on the courses in St. Mungo's College qualifies for the medical degrees of the Universities and the medical and surgical colleges in accordance with their regulations. A syllabus, giving details as to classes, fees, &c., may be had on application to the Secretary of the Medical Faculty.

The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has 600 beds available for the medical instruction in addition to an ophthalmic department, and it has special wards for diseases peculiar to women, venereal diseases, burns, and diseases of the throat, nose, and ear. At the dispensary special advice and treatment are given in diseases of the eye, ear, nose, and skin, in addition to the large and varied number of ordinary medical and surgical cases which in a great industrial centre daily require attention. Students at the college and hospital get the benefit of dispensary experience free of charge, and also better professional discipline and receiving clinical experience can be found than in the Glasgow Royal Infirmary. Clinical instruction in midwifery is given in the new Maternity Hospital by Prof. Jardine.

The appointments are as follows:—
1. Resident physicians and surgeons are appointed and live in the house free of charge. There is no salary. The appointment is for six months. These appointments may be renewed.
2. Non-resident physicians and surgeons (in the special subjects and for out-patient work) are appointed for six months. These appointments are renewed.
3. Clerks and dressers are appointed by the surgeons and are paid a salary of 15s. per month. No fees are payable for any surgical or medical appointment.

ROYAL INFIRMARY.—Fees: (1) Hospital attendance, dispensary, &c., perpetual ticket, £7 7s.; season ticket, six months, £2 2s.; three months, £1 1s.; separate payments amounting to £7 7s. entitle a student to a perpetual ticket on returning previous season tickets. (2) Clinical instruction, six months, £3 10s.; three months, £1 13s.

DENTAL CURRICULUM.—Students studying with a view to the dental diploma can obtain instruction in the following subjects: Physics, chemistry, anatomy, physiology, surgery, practice of medicine, and materia medica. The special dental courses may be obtained in the Dental School of the Incorporated Glasgow Dental Hospital, 18, Renfrew Street, Glasgow. Particulars may be had from Dr. M. Alexander, Esq., solicitor, 186, St. Vincent Street, Secretary.

THE ANDERSON COLLEGE OF MEDICINE, GLASGOW.

Founded in 1800. The modern, excellently equipped hospital buildings of the school are placed on the land adjacent to the Western Infirmary, and within four minutes’ walk of the University. Extensive laboratory accommodation is provided for practical anatomy, practical chemistry, practical botany, practical zoology, practical physiology, practical pharmacy, operative surgery, and public health.
The various courses of instruction quality for all the Licensing Boards in the United Kingdom, and for
the Universities of London, Durham and Edinburgh, Glasgow, under conditions stated in the calendars.
The courses in public health (laboratory and lectures) are recognized by the Universities of Cambridge,
London, etc. Session dates: 5th October to 12th December, 1914. For syllabus, apply to the Secretary of the Medical
Faculty, The Anderson College of Medicine, Glasgow, W.

The Carnegie Trust pays the fees of students at Anderson's College on conditions regarding which
practitioners may be nominated from Sir W. S. McCormick,

Class Fees.—For each course of lectures (anatomy, obstetric
ophthalmic medicine and surgery, aural, diseases of throat and nose, mental diseases, and
public health), first session, £2 2s.; second session, (in Anderson's College), £1 10s. Each practical
classes (except anatomy, chemistry, and public health),
mainly, botany, zoology, physiology, pharmacy,
operative surgery, first session, £2 2s.; second
session, £2 2s.

Chemistry.—Lectures, £2 2s.; practical
chemistry, £3 3s. Botany and Zoology.—Reduced fees
for lectures with laboratory work in botany or in
zoology, during same session, £3 3s.; for
lecture class or practical class separately, in botany
of anatomy, £2 13s. 6d. Obstetrics and Gynecology
(including hospital practice), £1 10s., diseases of throat and nose, and mental diseases, fee for
each course, £1 18s. Anatomy Class Fees.—Winter.—First
session, lectures and practical anatomy, £5 5s.; practical
anatomy alone, £2 2s. Second session, lectures and practical
anatomy (during 18 months), £4 18s.; practical
anatomy alone, £2 2s. Summer.—First session, course
special dental course (each including nervous system)
and practical anatomy, £3 3s.; regional anatomy
and special dental course alone, £2 2s.; practical
anatomy alone, £1 10s., osteology and practical
anatomy, £2 12s. 6d.; osteology alone, £1 11s.

Public Health Laboratory.—Fee for six months' course
£2 12s. Matriculation Fee.—For the year, 10s.;
for class alone in winter, 5s.; for summer session
alone, 5s.

Glasgow Western Medical School.—This school is
situated beside the principal entrance to the University
grounds and upon the Hillhead side, as the Anderson
College of Medicine is at the other extremity. Being
also near the Western Infirmary, this school is con-
veniently placed for students desirous of taking os-
mural classes. Lectures and demonstrations are
given, in the usual winter and summer sessions, on anatomy, surgery, medicine, midwifery and gyn-
ecology, ophthalmology, dermatology, diseases of
the ear, throat, and nose. Some of the classes qualify
for graduation and for Scottish diplomas. The usual
class fee is £2 2s. There is no matriculation fee.
Further information may be obtained from the Secre-
tary.

The Glasgow Royal Maternity and Women's Hospital.—
This hospital was, as regards the larger portion of it,
recently built after visits had been paid to a number
of British and Continental hospitals; by a committee
drivers, who gave careful preliminary study to all
the aspects of the question before building was begun.
The obstetrical and gynecological work is carried on in
the hospital, the wards being fully equipped, and
the old hospital building adjoining is used exclusively
as nurses' quarters. The hospital provides a training
school in practical obstetrics for medical students,
ladies' cases and midwives. The medical staff, both
on the obstetrical and gynecological side, and the leading
physicians in these departments in the city. Out-door
practice in the various quarters of the city is obtained
from the hospital as a centre. The labour wards in the
hospital are large, light and airy, and there is an
isolation block for septicaemic cases. Further information
may be obtained from the House Superintendent.

Among the other important institutions which assist
in making Glasgow one of the foremost places of medi-
cal education, there are the Infirmary, with 905 beds, adjoining the University and closely
connected with it; the Victoria Infirmary, in the
southern part of the city, with nearly 300 beds, where
clinical courses in a variety of subjects are given;
the Glasgow Eye Infirmary, with 100 beds; the
Royal Hospital for Sick Children, the largest hospital of its
kind out of London; the Royal Samaritan Hospital
for Women, etc.

END OF EDUCATIONAL NUMBER.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

SCOTTISH MEDICAL SERVICE EMERGENCY COMMITTEE.

The following gentlemen, representing the various
Medical Colleges and Universities of Scotland, have
formed themselves into an "Emergency Committee"
for the purpose of assisting to meet the immediate
difficulties, in regard to medical practice among the
civil population, which have arisen or may arise owing
to the departure of practitioners summoned to take
up military duty; it being understood that some 300
Scottish practitioners have been thus called away from
their localities, and that the numbers likely to be called
for at short notice. In large towns these numbers are
not numerous, and the rate of remuneration they
expect tends to become prohibitive. The Committee
proposed to the Council of the Royal Colleges
of Physicians and of Surgeons of Edinburgh, the Presi-
dent of the Royal Faculty of Physicians and Surgeons
of Glasgow, the Dean of the Faculty of Medicine,
University of St. Andrews; the Deans of the Faculty of
Medicine of the Universities of Aberdeen and
Dundee, and the Secretaries of the Universities, with the following additional names:
Dr. John Adams, Glasgow; Dr. G. C. Anderson,
Methil; Dr. John Gordon, Aberdeen; Dr. J. R.
Harland, Hawick; Dr. J. C. M'Vail, John Playfair,
and John Steven's, of Edinburgh; Dr. Norman Walker,
Convener. The Committee is now ready to receive
communications from medical practitioners in Scot-
land who are desirous either of obtaining or of offering
professional services in any of the following capacities,
indicated. All such communications should be
addressed to The Convener, Medical Emergency
Committee, Royal College of Physicians, Edinburgh.

GLASGOW AND THE RED CROSS.

The Glasgow Branch of the Red Cross Society has
four committees, upon which permanent representation
upon gifts in kind and upon work parties. The
two former are only for gathering information to pass
on to the Hospital Accommodation and Equipment
Committee of the Scottish Branch. The two latter pass
on what they receive to the Stores Committee of the
Scottish Branch. The Scottish Branch leaves all
matters referring to the purchase, storage and despatch
of medical and surgical stores, as before, under the
control of the secretary, Major Fleming. The Stores
Committee receives all gifts in kind and produce of
work parties from the county branches as well as the
Glasgow Branch; has requisitions passed on to it by
the Executive, which is the same purchasing subject to the
sanction of the Finance Committee. It is necessary
for these committees to complete these requisitions, and despatches same as
directed.

GLASGOW'S MEDICAL OFFICER.

At the outbreak of the war the Corporation Health
Committee appointed Dr. R. W. Haldane, chief
assistant to Dr. A. K. Chalmers, to be acting Medical
Officer of Health for the city during the absence on
Territorial duty of his chief, who is a Lieutenant-
Colonel in the Royal Army Medical Corps, Territorial
branch. We regret to record that he has been seized with illness and has had to be removed to
a nursing home to undergo an operation for appendicitis. In these circumstances the Health Com-
had testified in favour of his prison forcible feeding, that it was everyday medical practice, that there was nothing particularly novel about it, and that the statements so obviously untrue (especially after three prisoners had been very nearly killed) that naturally their authors insisted on their names being concealed.

Safe in like anonymity, your correspondent proceeds to give you a very round and quite outsize picture of the principles of suffragism, and secondly of my views, while finally he accuses me of "sickly sentimentality.

This is exactly the spirit of that notorious anti-socialist the "War" of a hundred years ago, with his aristocratic following, considers our condemnation of his violation of neutrality, his murders of wounded, of unarmed men, women and children, and of his destruction of cities and villages, as more sickly sentimentality. More than forty years ago, as a Privy Councillor of the Monarchy, "An Obscure Practitioner," has no place for humanity and civilisation in his ideas of national life and politics, let us leave him and consider Dr. Sers's misunderstanding of the suffrage movement and the present state of things.

Dr. Sers must begin at the beginning and study the history of the franchise movement since the middle of the 19th century. He will then learn that outrages have invariably been followed by the admission of the people of the country, not to take part in the work of their country, but also to have a voice in wlhat should be decided, and that all of them alike have to obey. The present outrages are, of course, a mere repetition of history from the time of Wilkes, of Captain Swing, and of the Reform Riots; the arson which Mr. Hobhouse first alleged to which all of them alike have to obey. The present outrages are, of course, a mere repetition of history from the time of Wilkes, of Captain Swing, and of the Reform Riots; the arson which Mr. Hobhouse first alleged to which all of them alike have to obey. Butchers were efficacious in drawing attention to the need for reform and enfranchisement. Dr. Sers, like our ancestors, instead of recognising the just claims of our fellow subjects, would rather continue the old method of trying to crush the natural evolution of universal suffrage which has already fruited in our more enlightened Dominions. He advocates forcible feeding now as a "deterrent," and compels it to hang him, which he also suggests is the proper way to deal with homicides. In the first place he might, I think, have done me the justice of acknowledging that it was I who, in my letter of the 26th, proved that prison forcbible feeding is used as a "deterrent" on certain prisoners, and was not, as he alleged on the 24th, "medical treatment of hunger strikers.

At any rate, he has learnt one fact. But, further, his analogue of hanging as a cure of homicide shows how little regard he has for his country. He says that the挂在 of criminals is a matter of national freedom and of social reform. Hanging does not deter. Surely every prison enactment of the last 100 years is a proof of that well-known fallacy. Surely, also, every hanging is an incitement to further crimes and crimes as we try to do diseases—namely, by prevention. We don't prevent homicide by hanging people after the event; the only way to prevent it is to attack the causes of homicide. Further, everyone knows that the cause of 95 per cent. of homicide is alcohol. The civilised method of deterring people from homicide, therefore, is not by hanging them after they have developed the homicidal impulse, but by preventing the sale of this vice while it enriches the brewer and his shareholders.

So, too, with the franchise. The stupid folly of the anti-democrat has led him on from the first gross injustice to be imposed upon the women who put the question constitutionally to Sir Edward Grey at his Manchester meeting, October 13th, 1909, to the brutality of forcible feeding introduced by Lord Gladstone in September of the same year; the breach of the pledge to the police at Westminster in November, 1910, and now to the false position in which our profession is being placed owing to this disgusting and grossly partial treatment of prisoners who hunger strike, and being voted for--not have--have but the power of protest against injustice. On this last point—namely, the way in which forcible feeding by prison doctors has totally destroyed British justice—I cannot under-

---

**LETTERS TO THE EDITOR.**

*We do not hold ourselves responsible for the opinions expressed by our Correspondents.*

**FORCIBLE FEEDING.**

To the Editor of The Medical Press and Circular.

Sir,—Dr. Sers and an anti-suffragist (who, of course anticonstitutional and terms him an "Obscure Practitioner") continue the discussion of this subject and of my facts, which with a sad misuse of our language they refer to as "quibbles." As to the last contention, it is, like all his class, so ashamed of his advocacy of this loathsome treatment of prisoners that he does not venture to append his name to the attacks he makes upon my views of political liberty. How typical of anti-suffragists.

His leader, Mr. McKenna, has also repeatedly refused to give even to the House of Commons the names of those medical practitioners who he stated to have testified in favour of his prison forcible feeding, that it was everyday medical practice, that there was nothing particularly novel about it, and that the statements so obviously untrue (especially after three prisoners had been very nearly killed) that naturally their authors insisted on their names being concealed.

Safe in like anonymity, your correspondent proceeds to give you a very round and quite outsize picture of the principles of suffragism, and secondly of my views, while finally he accuses me of "sickly sentimentality.

This is exactly the spirit of that notorious anti-socialist the "War" of a hundred years ago, with his aristocratic following, considers our condemnation of his violation of neutrality, his murders of wounded, of unarmed men, women and children, and of his destruction of cities and villages, as more sickly sentimentality. More than forty years ago, as a Privy Councillor of the Monarchy, "An Obscure Practitioner," has no place for humanity and civilisation in his ideas of national life and politics, let us leave him and consider Dr. Sers's misunderstanding of the suffrage movement and the present state of things.

Dr. Sers must begin at the beginning and study the history of the franchise movement since the middle of the 19th century. He will then learn that outrages have invariably been followed by the admission of the people of the country, not to take part in the work of their country, but also to have a voice in what should be decided, and that all of them alike have to obey. The present outrages are, of course, a mere repetition of history from the time of Wilkes, of Captain Swing, and of the Reform Riots; the arson which Mr. Hobhouse first alleged to which all of them alike have to obey. Butchers were efficacious in drawing attention to the need for reform and enfranchisement. Dr. Sers, like our ancestors, instead of recognising the just claims of our fellow subjects, would rather continue the old method of trying to crush the natural evolution of universal suffrage which has already fruited in our more enlightened Dominions. He advocates forcible feeding now as a "deterrent," and compels it to hang him, which he also suggests is the proper way to deal with homicides. In the first place he might, I think, have done me the justice of acknowledging that it was I who, in my letter of the 26th, proved that prison forcible feeding is used as a "deterrent" on certain prisoners, and was not, as he alleged on the 24th, "medical treatment of hunger strikers.

At any rate, he has learnt one fact. But, further, his analogue of hanging as a cure of homicide shows how little regard he has for his country. He says that the挂在 of criminals is a matter of national freedom and of social reform. Hanging does not deter. Surely every prison enactment of the last 100 years is a proof of that well-known fallacy. Surely, also, every hanging is an incitement to further crimes and crimes as we try to do diseases—namely, by prevention. We don't prevent homicide by hanging people after the event; the only way to prevent it is to attack the causes of homicide. Further, everyone knows that the cause of 95 per cent. of homicide is alcohol. The civilised method of deterring people from homicide, therefore, is not by hanging them after they have developed the homicidal impulse, but by preventing the sale of this vice while it enriches the brewer and his shareholders.

So, too, with the franchise. The stupid folly of the anti-democrat has led him on from the first gross injustice to be imposed upon the women who put the question constitutionally to Sir Edward Grey at his Manchester meeting, October 13th, 1909, to the brutality of forcible feeding introduced by Lord Gladstone in September of the same year; the breach of the pledge to the police at Westminster in November, 1910, and now to the false position in which our profession is being placed owing to this disgusting and grossly partial treatment of prisoners who hunger strike, and being voted for--not have--have but the power of protest against injustice. On this last point—namely, the way in which forcible feeding by prison doctors has totally destroyed British justice—I cannot under-
REVIEWS OF BOOKS.

The Medical Press.

REVIEWS OF BOOKS.

SEPT. 9, 1914.

DISEASES OF THE RECTUM AND ANUS.

The importance of diseases of the rectum and anus is well brought out by the statement that 1.2 per cent. of the population suffer from rectal ailments during some time of their lives. Mr. Lockhart-Mummery has written a readable and practical work which will be of great service to all engaged in the treatment of these diseases. The text is supported by a large number of references to the reports of the leading authorities.

The book represents the work of the author at St. Mark's Hospital and in private practice, and is full of valuable information. The author knocks the bottom out of several established ideas and gives good grounds for the rejection of them. For instance, he shows that the so-called ribbon-shaped motion is of no significance in the diagnosis of cancer of the rectum in the ordinary situation; that it is not necessary to divide the anus, to clear it of the margin of danger; that syphilitic disease of the rectum is a rare disease; and that it is possible to render the rectum as aseptic as other more favoured portions of the anatomy.

He draws attention to the importance of accurate diagnosis and the necessity of separating the many unimportant conditions from those requiring treatment. Every surgeon has seen lamentable instances of malignant disease of the rectum treated as harmless when a simple examination would have disclosed the real state of affairs. He devotes a special chapter to ano-rectal operations, but, we think, does not attach enough importance to local anaesthesia or analgesia. The chapter on fistula is particularly good and the causes of the healing or recurrence frequently occurring after operation are clearly set forth. We have seen no accurate summary of the different methods of treating fistula, and we believe that Mr. Mitchell has described them better than any other. We agree with the author that Whitehead's operation for piles is not necessary in most cases, and probably have been granted. The Report shows how serious this matter is bound up with the sale of bogus curative articles. Kindly submit the circulars.

It points out that the sum it estimates as spent by the nostrum mongers in advertisements does not include that of swindlers like Masacre, the eye quacks, the deaf mutes, the electric belt makers, the curers of ruphpture without operation or /aktir generally." Based on the evidence in this present report, we must now formulate a demand for a Select Committee on the latter question. I hope always to have the chance to say that the whole evil of quackery could all be put an end to by amendment and improvement of common law. Quackery of all kinds is a systematic process of getting money, and the alterations in the law suggested by the Committee will put an end to this.

If a man can be punished for selling marmalade as butter, he can be more severely punished for selling coloured paraffin as a cure for cancer; and an unqualified man may be easily prevented from practising as a solicitor under the remotest false pretence, there can be no difficulty in preventing unqualified fraudulent quacks not only from practising, but from effectually poisoning themselves off on the public as legally qualified medical men. I am, Sir, yours truly,

Henry Sewell.

The Old Boy. Earlwood Common.

September 20th.
that a simpler procedure is usually sufficient. There are a few printer’s errors, and the illustrations are sometimes crude, but these are small matters in a book of such general excellence. We heartily recommend this book as a sound summary of the best practice in this department of surgery.

**LITERARY NOTES.**

Masek, Bailliere, Tindall and Cox announce that a tenth edition of that important work for students, Rose and Cailes’ “Manual of Surgery,” with 1600 coloured plates and 1000 illustrations, will be ready in time for the winter session. It is sixteen years since the publication of the first edition of this work, and so world-famous has it become that 32 editions and reprints have been necessary in that period. A seventh edition of Prof. Stewart’s “Manual of Physiology” is also promised from the press of the same firm. In the new edition Prof. Stewart has replaced a large number of the old figures and added some fresh ones. He has made a thorough revision, and has greatly improved the book by splitting up the chapters into distinct sections, in order to assist both teacher and student.

At the present time there is a great demand for manuals of first-aid and ambulance. A convenient pocket book, suitable for the pocket book, for the medical practitioner J. P. Sutherland’s “First Aid” (the 35th edition, revised and enlarged, of which has been edited by Dr. Halliday Sutherland. Within the small compass of 45 pages packed away an amount of useful information, covering the whole ground of first aid to the injured and sick. The price is only threepence, and the publisher is Mr. S. O. Madigan, 3. Ivy Lane, E.C.

**MEDICAL NEWS IN BRIEF.**

The National University of Ireland.

The Senate met on Tuesday, September 11th, and had under consideration the reports of the Examiners upon the special examination for the M.B., B.Ch., B.A.O. degrees recently held by the University in view of the present national crisis for the purpose of facilitating the immediate entry of successful candidates for military service in the Navy or in the Army, and agreed to award the following passes and honours:

Special M.B., B.Ch., B.A.O., Degrees Examination, 1914. — The following are the results of the examination held in University College, Dublin, for students of University Colleges, Dublin, Cork, and Galway, Students of University College, Dublin. — First-Class Honours: John A. Field.

Second Class Honours: John B. Minch and Michael McKeever, B.A.

Second Class Honours: John Kennedy, Thomas F. Kennedy, Vernon O’Hear Cussen.

The following candidate has been exempted from further examination in medicine, orthopaedics and midwifery: Thomas H. Richardson, University College, Cork.

The Senate adopted a resolution that a saddle-line should be issued to the effect that the candidates will arrange, as far as it may be possible, to take the stipulations of the University, that are subject to University regulations, which are unsuitable for the Crown during the war, shall not be proceeded in any way in his University course on account of such service.

**Munificent Gift for Medical Research.**

At a meeting of the Governors of the London Hospital last week it was reported that a gift of £1000 had been promised by Mrs. Patterson for cardiac research work.

**Society of Apothecaries of London.**

The following is a list of candidates who, having passed the necessary examinations during August and September, have been granted the L.C.S. diploma, entitling them to practice Medicine, surgery, and midwifery:— Drs. T. H. Beresford, H. Brodie, J. G. B. Hearn, R. Jennings W. M. Larcher, H. J. Lea, D. W. Newton, L. E. F. James, R. V. Powell, and C. J. B. Way.

The Royal College of Surgeons, Edinburgh, announces that the South African College, Cape Town, is now recognized as a school of anatomy and physiology for the course required for admission to the second examination of the Council Board of the Royal Colleges of Physicians and Surgeons.

**MEDICAL WAR ITEMS.**

War Risks.—The following resolution has been passed at a special meeting of the Executive Committee of the Medical Society, Annuity and Life Assurance Friendly Society:—Any member serving with His Majesty’s forces on active service abroad shall be allowed to retain the annuity, or an equivalent amount, during his absence from the United Kingdom, and shall, on return to the United Kingdom, come into sickness and accident benefit. Any member serving with His Majesty’s forces while in the United Kingdom shall be held fully covered for sickness and accident, while absent. An annuity insured for life assurance serving with His Majesty’s forces either abroad or in the United Kingdom shall not be charged any extra premium and shall be held fully covered.

Birmingham medical men have circularised the patients of local doctors called to the front, offering medical attention on their behalf, and exhorting them to keep faithfully to their particular doctor on his return.

The ready offer of hospitals has made it unnecessary — except in one or two cases—for the authorities to utilise buildings which are not already adapted as hospitals. The Yarrow Convalescent Home at Broadstairs is one of the few buildings which are being converted. Where such buildings are being used the necessary alterations are being made.

At a meeting of the Council of the National Medical Union on Saturday last, September 11th, the following resolutions were passed:—In view of the great increase of business, the National Medical Union is prepared to submit a list of its members who are willing to place their services at the disposal of the War Office.

**NOTICES TO CORRESPONDENTS. &c.**

EP. Correspondents requiring a reply in this column are particularly requested to write at once, in order to avoid the practice of signing themselves “Readers,” “Subscribers” “Old Subscribers,” etc. Much confusion will be avoided by adhering to the rule.

**SUBSCRIPTIONS.**

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Postal orders, drafts, &c., should be addressed to: Messrs. Longman, Green, Longman, Longman, Roberts, and Green, 17, Princes Street, London, W. For Canada, The Longmans, Green and Co., 108, Yonge Street, Toronto, Ont. For Australia, Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

**ADVERTISEMENTS.**

For One Insertion—Whole Page, 2s.; Half Page, £2 10s.; Quarter Page, 6s. Green, 1/2; 6l.

The following are our special agents for Canada—Messrs. E. A. D. and S. E. Dowling and Sons, of Toronto, Ont. For Canada, South Wales, Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.
Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Applications were requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 6, Henrietta Street, Strand; if resident in Ireland to the London office, in order to save in forwarding from office to office. When sending sub-

Original Articles or Letters intended for publication should be submitted to the Editor and if not authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

NOTICE—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

C. H. S, (Brighton).—Letter received, contents noted and sent to Shrewsbury.
M.R.C.P. (Liverpool).—We should have been glad to give space to your communication, but we do not see that it applies to the argument it is intended to refute. As we understand you desire to raise a point of importance to a certain class of practitioners, it will afford us pleasure to give you space for this purpose if desired.

NOTICE TO HOSPITAL SECRETARIES AND COLLEGE DEANS. The Editor wishes to thank the above gentlemen attached to the various Schools and Hospitals for supplying him with the information from which the foregoing pages have been compiled, and to extend to them his most cordial thanks.

This number is mainly devoted to information necessary for students intending to join one or other of the various medical colleges. They are requested by those who, having passed their curriculum, are about to enter the ranks of the profession, much of the ordinary matter which usually fills our columns is necessarily deferred till next week.

GRATUITOUS COPIES. A very large number of copies of this issue are being sent gratuitously to hospitals and institutions of all descriptions, especially reading-rooms, clubs and large hotels in the United Kingdom, and to all the leading journals in America, India, the Colonies and on the Continent; should any of our readers desire to present a copy to a patient or friend who contemplates sending his son to a medical college, it will be supplied to him with a duplicate free of cost on receipt of address.

D. J. Watton.—Thallium acetate may be used with safety for the removal of downy skin from the upper lip which is unsightly for esthetic reasons. Sabouraud gives the following formula:—R Thallium acetate 0.30 gram, zinc oxide 2 gram, vaseline 10 gram, lanolin 2 gram. The action of this salve is slow and progressive.

Vacancies.
Royal Albert Hospital, Devonport.—House Surgeon. Salary £90 per annum, with board and laundry. Applications to the Chairman of the Selection Committee.
Hulton Dispensary, on the outskirts of Stretford Road, Manchester.—House Surgeon duly registered and fully qualified. Salary £160 per annum. Applications to the Secretary should be accompanied with testimonials, at once to Colonel Brown, Stretford Road, Manchester.
Manchester Northern Hospital for Women and Children, Park Place, Cheetham Hill Road, Manchester.—Surgeon. Salary £250 per annum, with board and laundry. Applications to Mr. Hubert Tonge, Secretary, 38 Barton Arcade, Manchester.
Northern Dispensary, Oldham.—Surgeon. Salary £120 per annum, with board, residence, and laundry in the Hospital. Applications to the Secretary.
Sheffield Hospital, near Durham.—Medical Officer. Salary £200 per annum, with board and lodging. Applications to the Secretary, Mr. W. M. Gilboy, 20 Mount Street, Sheffield.
Rotherham Hospital.—Assistant House Surgeon. Salary £120 per annum, with board, lodging, and washing. Applications to the Secretary, W. G. Roberts, 8 Moorgate Street, Rotherham.
The University of Sheffield, Department of Pathology.—Junior Demonstrator in Pathology. Salary £200 per annum. Applications to W. M. Gilboy, Secretary, Nottingham City Asylum.—Junior Assistant Medical Officer. Salary £200 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent.
The University of Liverpool.—Fellowship in Medicine.—Johnston Chair of Medicine. Salary £100. Applications to Dr. C. E. Jordan, Senior Assistant, to Edward Carey, Registrar.

Appointments.
Bond, C. Shaw, M.B., B.C., M.R.C.S., L.R.C.P. Lond., Medical Officer and Public Vaccinator for the Hammersmith (Hamp-

HUMLE DISPENSARY, DALE STREET, STRETFO RD, MANCHESTER.
WANTED a HOUSE SURGEON duly registered and fully qualified. Salary £200 per annum, with apartments, coal and gas. Applications, with testimonials, at once to the Medical Superintendent.

DEATHS.
Gowland, William Percy, F.R.C.S.Eng, to the Chair of Anatomy at the University of Otago, Dunedin, New Zealand.
Salisbury, William, F.R.C.P. Lond., Assistant Resident Medical Officer at the Queen Charlotte's Lying-in Hospital, Maryle-

Deaths.
Dalestreet, Sept. 3rd.—Mr. J. W. G. Dobson, late of the late Dr. Matthew Debnall, of Brapford, Shropshire, aged 72.
Hicks.—On Sunday, August 30th, at 119 Auburn Road, N.E., Dr. George Borlace Hicks, in his 87th year.
Evs.—On August 28th, at 43 South North, Southsea, Dr. Stuart Hathaway Reid, M.A., late of the East London Hospital for Children, Shadwell, aged 49.

Births.
Early.—On September 1st, at 15 Lydiatt Terrace, Cheltenham, the wife of P. M. Earle (British Guiana Medical Service)—a daughter.
Lacey.—On Friday, August 28th, at 194 Barrague Road, Wool-

Marriages.
Darling.—On September 1st, at St. Giles' Cathedral, Edinburgh, Alexandra Gray Banks, M.R.C.S. (Edin.), to Evelyn Isabelle, daughter of the late William Stepney, Stockbridge, Hampshire, aged 26.—a son and heir.
Chevening Lodge.—On September 1st, at St. Mary's Church, West Kirby, M.B., M.R.C.S., young son of the late Alfred Fountain Browne, Esq., and Mrs. Fountain Browne, of Ealing, to Miss Winifred Anne Sanderson, eldest daughter of Mr. and Mrs. E. R. Billington, of West-Kirby, At home, October 15th and both, No. 4 Hamilton Square, Birkenhead.
Hilton.—On September 1st, at 2nd, at the Parish Church, to Albert Watson, M.B., of Newton Abbott, Devonshire, youngest son of the late C. H. E. Pater, Esq., C.B., and of Mrs. Pater, of Newton Abbot, to Dorothy, daughter of the late Reverend F. H. Vizard, Vicar of Herne Hill, Farnborough, aged 29, daughter of Mr. and Mrs. C. H. Vizard, of St. Matthew's, Latimer Road, to Miss Ethel, of St. Edward's, Isip, and Margaret, youngest daughter of John Potts, Esq., of Knapp Hill, Wandsworth.
Price.—On September 2nd, at Chefield Parish Church, to Walter Patey, M.D., of Newton Abbott, Devonshire, youngest son of the late C. H. E. Pater, Esq., C.B., and of Mrs. Patey, of Newton Abbot, to Dorothy, daughter of the late Reverend F. H. Vizard, Vicar of Herne Hill, Farnborough, aged 29, daughter of Mr. and Mrs. C. H. Vizard, of St. Matthew's, Latimer Road, to Miss Ethel, of St. Edward's, Isip, and Margaret, youngest daughter of John Potts, Esq., of Knapp Hill, Wandsworth.
Robinson—Seydon.—On September 1st in Painshaw Church (quietly on account of the war), Dr. William Robinson, son of Andrew Robinson, of Lower Assington, Eyam, to Miss Winifred Helen, second daughter of the Rev. W. H. Seddon.
Shaw.—Seydon.—On September 1st, at the Church of our Lady of Victories, Kensington, to Dr. George George Sharpe, A.M.C, son of the late Dr. James Sharpe, of Dublin, to Margaret Sarah, daughter of Mr. and Mrs. David, of 2, St. Mary's Avenue, to Miss of St. Mary Abbott's Terrace, Kensington.
Vivian—Ballett.—On September 3rd, at the Parish Church, to Edweld, Harold Sugden Vivian, of R.S. Lond, Winchmore Hill, Middlesex, to Alice Winifred, daughter of Frederick Boreland, of 18 High Road, Lee, Kent.
Among the many unrecorded deeds of gallantry under fire must be mentioned the heroic and self-sacrificing acts unceasingly performed by medical officers serving under the Red Cross. One of the most ghastly features of the present war is the manner in which this emblem, sacred to the cause of humanity, is honoured, or rather dishonoured, by the enemy. In consequence of these repeated acts of outrage the work of the Red Cross men has been rendered doubly hazardous, and many noble deeds performed in the face of such increased risks will never see the light of day in cold print or be mentioned in dispatches. They are all inscribed, however, by the recording angel in imperishable characters upon his eternal scroll. It is reported that on August 25th, when Louvain was razed to the ground, Dr. Noppe, Principal of the Medical Faculty of the University of Louvain, was about to visit one of his servants in the hospital, who had been shot in three places. At this time the famous library was already burnt out. He attended to the girl's wounds and hurried back to his residence, only to find it in flames, despite the fact that a large Red Cross flag was flying over it, and that a notice was upon the door to say that a Dutch medical man lived there. The professor and his wife remained in the cells of the hospital to attend to the physical needs of some 150 wounded patients, and did what they could to relieve the sufferings of the distracted townsfolk. All honour to the men who love not their lives unto the death, and who remain faithful to their posts as ministers of healing.

In the provinces recruits for the new armies are in some instances examined by local civilian practitioners. A small fee, half-a-crown, is paid by the War Office for each examination. Considering the amount of skilled service and the necessity for rigid apseisis the rate of remuneration does not err on the side of extravagance, and a private patient would very properly be expected to pay a much larger fee. The public, however, has acquired a rooted belief that medical service should be obtainable either free or for a ridiculously small sum. In various Yorkshire newspapers an objection has been raised to the amounts paid to local medical men for the examination of recruits. In one instance a correspondent writing under the signature "F.R.C.S.," states that he devotes two hours daily—all the time he can spare—to this duty, in return for which he receives ten shillings. On the other hand, he points out that medical men will be hard hit by the war, owing to the number of bills that will remain unpaid. That fact should be appreciated by the Government in their dealings with the medical profession. It would, indeed, be a bad stroke of political economy to foster conditions that tend to reduce the efficiency of the medical service of the nation.

The importance of anti-typhoid inoculation has been pretty widely recognised not only by the medical profession, but also by the War Office and the public at large. Statistics apparently prove beyond doubt that the incidence and mortality rates are thereby reduced, not to mention the detection of that most dangerous of camp inmates, the typhoid carrier. From a public health point of view it is highly desirable to exclude as far as possible the introduction of enteric fever by soldiers on their return from the war. There is no need, however, to labour the point. Prophylactic inoculation against typhoid fever is a scientific precaution of great value, and should be administered to all British troops who join our armies in the field or, so far as that goes, who are placed in camps at home. The difficulty of the Army Medical Department will be to find medical men to administer the typhoid vaccine, a little operation that requires skill and experience. In Scotland the Royal Colleges have placed their laboratories at the disposal of the War Office. In London the Army Medical Service could secure ample help of the kind in some of the first-rate clinical laboratories attached to various large and small hospitals. Some of the larger hospitals are depleted of staffs and overburdened with wounded soldiers, but more than one small special hospital we could mention would be able to administer, if necessary, several hundreds of typhoid inoculations daily. The attention of Sir Launcelot Gubbins, Director-General of the Army Medical Department may be drawn to this matter. An offer to do this particular work has been made by a well-known professional association, which, if we mistake not, has been organised and supported for very different purposes.

Books and the Man. The majority of medical and scientific books differ somewhat from many works of general literature in that the former tend to serve the needs of a given generation of students. We prize and regard with reverence the weighty tomes and works of reference produced by the great medical teachers of half a
century ago, but they do not figure upon the list of books recommended for candidates for present-day examinations. Some textbooks, indeed, are fortunate enough to run through a large number of editions and are ousted from their place only with great difficulty by insistent claims of some pushing rival. The shelves of the second-hand bookshops bear abundant testimony to the comparatively short life of the average medical work. And so it must ever be in the case of such a progressive science as that of medicine, fresh discoveries in which spring to light with startling rapidity may seem perilous originals, to the tyro to know what books he ought to purchase at the outset of the career. The student will do well to be guided in this all-important matter by his teachers and maters and only to purchase those textbooks that will be of immediate use. As he proceeds further in his medical studies his library will of necessity, increase. Broadly speaking, it may be said that the aspirant after a medical degree at one of the Universities will require to spend more upon books than he who is bent upon obtaining a diploma from one of the colleges or corporations authorised to grant such. In his last year or two the senior student will need to supplement his textbooks by reading original works in the various medical journals. Finally, it should be remembered that the most successful practitioner is he who has the broadest outlook, therefore, care should be taken to supply all the mental faculties with that *pabulum* which can only be obtained by a liberal course of general reading.

The *Importance of Physical Training.* The alleged inferiority of the modern athlete is the keynote of a communi-
cation from the pen of Sir Lauder Brunton to the *Times Educational Supplement.* In the absence of comprehensive statistics dealing with the physical measurements of ancient as well as modern athletes it is not easy to judge with scientific precision whether the degeneration of limb, so loudly complained of by dramatist writers, is a real cause for national searching of heart. There does not appear to be any lack of a pure spirit of sportsmanship in the country today, so far as the physical condition of our national interests are concerned, but it is just open to question if sufficient attention has been paid in this country to regular, systematic training in physical exercise. Each of the great national games and sports exercises certain but seldom the whole of the muscles of the body, whereas the Swedish drill, intelligently persevered in during childhood and youth, would go far to remove any reproach that may be hurled, rightly or wrongly, against the athletic side of our present educational system. The establishment of chairs of physical training in the Universities of this country, after the manner of that already existing in the University of Pennsylvania, as well as the introduction of sports masters in every school who would be directly responsible for all physical training, have been suggested as being among the most practical means of improving the muscular fitness of the nation at large.

The administration of anaesthetics by medically unqualified or un-
and Unquali- registered persons is an obvious tied Practice, danger to the public. The safe administration of anaesthetics demands a combination of technical skill and knowledge that cannot reasonably be looked for apart from a thorough medical training. There is, of course, an unavoidable margin of deaths that must occur during anaesthesia, just as there must be, say, in a given fever, such as malaria or measles, or in the operation of ovariotomy, even when the patient is placed under the best modern conditions. Those deaths, however, represent the minimum, and the number rises rapidly as the medical competence or resources of the medical men concerned. A comparison, for instance, of the deaths under anaesthesia at two of the largest hospitals in the kingdom revealed a startling difference in results. A change in administration methods of the less favourably dis-
tinguished institution brought about a remarkable diminution of this most distressing form of fatality. These facts prove, first, that to a certain extent anaesthetic deaths are avoidable, and, secondly, that special training and experience are needed to produce really competent anaesthetists, even amongst qualified medical men. It goes without saying that in the hands of medical men qualified persons the administration risks attending the anaesthetics would be greatly multiplied. To permit such irregular practice is illogical on the part of a State that demands a rigid course of special study and training by repeated examinations before any person is granted a legal qualification to practice medicine or surgery.

It seems, indeed, a self-evident fact that the promiscuous administration of anaesthetics must constitute a grave public danger. The need of legislation on the subject has been urged upon the Government time and again. Will they consent to bring before the public, and the lives of our fellow-citizens—that is to say, if he exercise the small amount of caution needed to keep within the four corners of the law. On the other hand, as a matter of public safety, a considerable expenditure of money and labour, secured a State medical qualification, finds himself subject to all sorts of pains and penalties should he offend not only against various written and unwritten laws of his profession but also against the general moral and penal laws of society. In view of the peculiar conditions of medical practice it is right and proper that a high ethical code should be en-
forced. But what about the topsey-turveydom of a system that protects society so sternly against the lapses of the qualified practitioner but leaves it completely at the mercy of the cancer-curer, the bone-
setter, the venereal quack, he vender of worthless nostrums and the rest of the crew of parasites who flood the world with their lying advertisements?

The Medical Roll of Honour. Since the date of our last issue the list of British losses in the war have steadily mounted until it has reached a total of 18,700 (on the evening of September 18th). Additional names are those of—Killed: Capt. A. S. Williams, R.A.M.C. Wounded: Capt. McConaghy, R.A.M.C., Lieut. W. K. Morrison, R.A.M.C., Capt. C. W. Holden, R.A.M.C., Missing: Capt. P. O. P. Davy, R.A.M.C., Lieut. E. Davies, R.A.M.C., Capt. H. C. Hildreth, R.A.M.C., Capt.
THE REPORT ON PATENT MEDICINES.

At the present moment public attention is engrossed by the terrible war which is devastating the Continent of Europe. Matters of social moment accordingly pass by unnoticed amid the stress and anxiety of the Titanic conflict that has been thrust upon the people of the United Kingdom.

At such a juncture, then, the recently issued Report of the Select Committee of the House of Commons upon Patent Medicines is not likely for some time to come to secure that amount of publicity and interest which is warranted by its outstanding importance. It is, of course, impossible to discuss a document of this kind within the limits of a brief article, but readers will find its salient results elsewhere in our columns in the shape of the findings and the conclusions of the Select Committee.

Readers will observe generally that it clears the ground for the long delayed reform of an evil that strikes deep into the roots of social well-being, inasmuch as the evil type of proprietary nostrum damages its victims in pocket, in health, and, above all, in the inducement to substitute worthless in place of skilled treatment. The Committee carefully ranges patent proprietary medicines into non-secret and secret remedies. The non-secret include genuine and valuable drugs, such as adrenalin and urotropine; and others that owe their attractiveness to skilful combinations, or to the use of an excipient that may be itself secret. Secret remedies, on the other hand, include simple medicinal substances that may be harmless except in their misleading claims to curative virtues, or they may contain dangerous drugs, or be simply fraudulent, which, in the words of the Report, "are, and are known to the makers to be, cruel frauds: and the sale and advertisement of them should be prohibited under drastic penalties." From this passage readers will gather that the Report is of an outspoken nature calculated to secure the approval of the root-and-branch reformer, and such indeed is the case.

The survey of existing British law is not altogether satisfactory—the Committee deal simply with the Patent Medicine Acts of 1862, 1884, and 1812, and review the various laws whereby the fraudulent representation and other evils of the quack medicine trade might be restrained. It ignores the fact that there is a great mass of legislation dating from the days of Henry VIII., whereby summary powers were conferred upon the Royal College of Physicians of London and upon other bodies to seize and destroy false medicines and punish the vendors thereof.

Much of this restrictive legislation is unenforced, but possibly the Committee thought it wiser to refrain from a survey of laws that have fallen into desuetude. Among its emphatic findings, we note the following: (6) That no Department of State and no public officer is charged with the duty of controlling the sale and advertisement of proprietary remedies in this country; that the Home Office and the Local Government Board are virtually powerless in this respect; that the Privy Council Office, though supposed to be specially concerned with the sale of drugs, has no initiative in the matter, and, in fact, it fulfils no useful function in this connection. (7) That the existing law is chaotic, and that successful prosecution for fraud in the advertisement and sale of secret remedies is fraught with the greatest difficulty, though the Public Prosecutor has perhaps not sufficiently tested the power of the existing law in respect to such cases. (8) That consequently the traffic in secret remedies, except as regards scheduled poisons and the grosser forms of impropriety is practically uncontrolled in this country.

A similar firm handling is evident in the recommendation, which, if carried out, would practically put an end to one of the most nefarious forms of money-making that has hitherto defiled humanity's ceaseless struggle for existence.

The Select Committee, at any rate, has done its best to expose and check the evil. The chairman, Sir Henry Norman, himself a distinguished journalist, has faced the question of newspaper advertisement, which is the breath of life to quackery, both fairly and squarely. Standing for the best traditions of British journalism, his remarks will no doubt have a due effect upon the latter day cynicism of the so-called "yellow press," which thrives on the weaknesses of mankind, and appraises all human effort from the single standpoint of material self-interest.

The Report is specially welcome to the MEDICAL PRESS and CIRCULAR, which, in season and out of season, has for more than two generations raised its voice in protest against the evils of quackery. It is a matter of inexpressible gratification to find our contentions more than supported by the formal finding of a governmental investigation.

Our readers will doubtless join us in a devout wish that the labours of the Select Committee may be attended ere long by the fruition of legislative approval. The present century has witnessed various social changes of a far-reaching nature, a fact that renders one hopeful that the Report under notice may not share in the oblivion that has consigned many a similar document to the forgotten dust of our national archives. It will be our duty when the termination of the war affords more leisure for the consideration of social reforms to discuss in detail many of the principles, findings and recommendations of this admirable Report.

Now that the Report of the Select Committee on Patent Medicines is published, we wonder what notice will be taken of it in the daily Press. The Report contains twenty-eight pages, not including the evidence, and goes fully and fearlessly into the matter before the Committee, and it is not too much to say that whatever public will hear much about it. We know as well as anybody that a newspaper is not primarily out for philanthropy. A paper cannot live upon circulation alone, but needs every word that proceeds out of the mouth of the advertiser. That is the real difficulty. We saw it in the case of "The Rocket," with such forceful publicity. The large, unadvertised proprietary frauds. Legislation is our only hope, and the influences that are brought to bear to avoid unpleasant publicity will be exerted to their fullest to scotch any effective bill. We need a crusade. Nowadays a crusade demands publicity for its success, and the public are against it the voice crying in the wilderness will seem still and small. We must keep on hammering away. We must never forego an opportunity of telling the truth about a patent medicine. Not with vague and abusive vapidations, which may be impouted by the ignorant to competitive jealousies, but with cold facts relating to composition and price, that will appeal to the pocket of the prospective purchaser. No one will pay half-a-crown for a couple of draughts of salt and sugar when he knows how he is being had. To ensure this we must take the trouble to learn something about these enemies to the public health. We study bacteria to defeat their machinations and we must do the same with the cure-all frauds.

Hoppickers and Hygiene.

The announcement that certain of the refugees from the Continent, who are daily arriving in this country, have been drafted into the hopfields, there to find employment, makes one pause for a moment to consider what provisions exist for looking after the health of this large body of workers. It is suggested that, when the pickers were dumped down, as it were, in large numbers into a district with little or no regard for the needs of ordinary sanitation and decency. Private enterprise, so often the pioneer of official action, was not long in making the attempt to ameliorate the physical lot of hoppickers during the time of their harvesting operations. The late report of the Royal Commission, upon the lodging and accommodation of hoppickers has been recently issued by the Local Government Board. During the present season it seems more than likely that there will be a greater strain than ever upon the accommodation provided for the pickers, and increased inspection will certainly be necessary this year. It is suggested that the attention should be paid to the sanitary requirements of tents, special huts, and farm buildings utilised for housing the pickers. Private accommodation suitably screened and protected should be provided in due proportion to the number of pickers. The water supply should be free from pollution, and if it might be said, such supply should be protected from contamination by the refuse and sewage of a hoppers’ encampment.

Between Two Stools.

Most of us have at some time or another met the man who is always dosing himself in vain efforts to preserve his youth. Alzheimer, from the fact that a stimulant and takes one; alcohol, strychnia, ammonia, or what not. Next he realises that he has rather overdone the trick, and he looks about for something to soothe his raw nervousings into some sort of comfort. We know this class of man, and find him hard to deal with. He has no settled policy about himself, and no outstanding feature of folly to which we can direct our attention. National mental state is at present rather like this man’s. It is not our fault. Mr. Wells says it is the fault of what he calls the "official" or "expert" mind, and he instances the obviously poor recruiting posters that adorn our post-offices. The fact remains, however, that we are capable of low and absurdly disgusting alternation. One week the cry is "carry on" and "business as usual," and the next we are called on in the name of King and country to leave our occupations whatever they may be and to join Lord Kitchener’s army. We are all ready and anxious to do what is right, and we are ready to make any sacrifice that will may be called on to give, but we must be told what it is that we are really wanted to do. No man will rise up and leave his practice and his family if he is likely to be told the next week that he would have done better for the land he loves by sticking to his daily round. Doctors on the whole have little temptation to leave their work. Some businesses have almost gone out of the Market Board, and there is a demand for the new doctor as is busy as ever. If we are wanted we are here and ready. We will trust our neighbours to do our work and to look after our interests till, and if, we return. But we need a charted way between the Scylla of shirking our duty to the country on the one hand and the Charybdis of careless-ness of our future on the other. We know the Government has its hands full at present and we hate grouse, but if we do not say what we want we cannot expect to get it.

A Nation’s Manhood.

"England considered no sacrifice too great which in the important struggle in which she was engaged." Thus wrote F. de Bourrienne in his "Life of Napoleon," with reference to the Peninsular War. That is how a Frenchman, Napoleon’s private secretary, recognised the efforts being made by England to subdue the forces of his master. Almost a hundred years have passed, and now we find ourselves again in the throes of a similar struggle. The sacrifices of the past have become those of the present if England is once more to do her share in bringing to his knees an unprincipled usurper of the rights and liberties of the nations of the world, that nation is England, as a nation, doing her best in the struggle before her? If so, how is it that many thousands of her sons, physically fit and capable,
withhold themselves from enlistment? How is it that Lord Kitchener should have to plead so earnestly for the recruits of which he is in need? Repeatedly he has affirmed that he wants every man that he can get. The Government has endorsed his appeal, and yet in the crisis in which this country is involved, the young manhood of the nation is not ashamed to continue the pursuit of pleasure, ignoring their duty. That heritage which the Empire now enjoys through the sacrifices of our ancestors is a sacred trust. We must support, maintain, and protect it, whatever the cost, unsullied, not only for ourselves but for those who succeed us.

The Philosophy of the War.

One of the most interesting occupations we can give ourselves is the tracing of tendencies. In the present war our sensibilities are daily swamped by sensational but unimportant details of outpost engagements and survivors' stories, it is a cooling change to rummage in the dusty past in our efforts to find a thread to lead us from some dim beginning through misty means to the crystalline calamity that now confronts us. There are people who attribute the war directly to Nietzsche's influence on the German people. It would give the supposition a greater appearance of probability if the attention were turned to the influence which Nietzsche is popularly supposed to have taught. The inventor of the Superman is usually credited with having taught a ruthless individualism and a brutality fully justified by the mere fact of its own existence, and because he was unfortunate enough to end his days in a madhouse, and to be the author of mystifying and unconventional phrases like "I should only believe in a God that would know how to dance," he is generally supposed to have reached his apotheosis in the German military aristocrat of the present day. Of course, such a view is unjust. The exhortation that he so ably directed to the German people, with what must seem to us some sinister foreboding, was "to have fidelity, and for the sake of fidelity, to risk honour and blood, even in evil and dangerous courses." This alone must check our assumption that the Teutonic policy is based on Nietzsche. Still, he was an individualist and the present war was essentially un-democratic in inception. Which side we take reckless autocracy bears the responsibility. In even allegedly representative countries those in power must some day answer for their actions. The brake of the average opinion checks any thoughtless or contemplated recklessness. We are not blind worshippers of Demos, but we see that pure individualism presupposes that the most powerful men are also the best, with which proposition we cannot agree. Matters affecting a whole people and which are comprehensible by the man-in-the-street must depend for their successful conclusion on his considered approval.

The Intravenous Injection of Mercury in Syphilis.

Now that salvarsan and neo-salvarsan will be practically unobtainable until such time as British chemists can be found to undertake its manufacture, we may well look around for other remedies for use in cases of syphilis. If we are compelled to fall back upon mercury we have the assurance that it is anything but a broken reed, in fact, it will probably remain the best anti-syphilitic drug for a long time to come. Those who have done their best persistently to discredit its efficiency will now have only too glad to avail themselves of its remedial action. At the same time, mercury needs to be administered with great care and not in a haphazard fashion. Some excellent results in the treatment of syphilis have been obtained by the intravenous injection of the bichloride of mercury by Drs. J. Kingsbury and Paul E. Becher, of New York (a), in doses of one-sixth to one-third of a grain in distilled water, the amount of fluid injected rarely exceeding 12 c.c. The advantages claimed for the intravenous route are the immediate introduction of the curative agent into the circulating fluid, rapid therapeutic results, mathematical dosage, and an absence of pain. Too great concentration of the bichloride solution may give rise to some phlebitis, which should be avoided. The benzaote of mercury was also employed in a 1 per cent. solution, the dose being from 2 to 12 c.c., but it was inferior to the bichloride. The method is not recommended as a routine but for use in selected cases. There is now abundant room for a full trial of the new French substitute for neo-salvarsan, which is said to be more intensely fatal as regards the spirochaetes of syphilis, although not quite so effectual as a tonic.

PERSONAL.

DEPUTY-GENERAL-SURGEON P. M. ANDREWS, R.N. (retired), has been appointed to Portsmouth Dockyard.

DR. C. HASTINGS PHILIP, M.P., B.C. Cantab., has been appointed Honorary Anaesthetist to the Herefordshire General Hospital.

SIR ARTHUR CHANCE has been appointed a member of the First Senate of the National University of Ireland in succession to the late Sir Christopher Nixon.

PROFESSOR DAVID WATERSTON, M.D., of King's College, London, has been appointed Bute Professor of Anatomy at St. Andrews University, in succession to Professor Musgrove.

DR. D. G. THOMSON, Superintendent of the Norfolk County Asylum, delivered the Presidential Address on taking the office of President of the Medico-Psychological Association of Great Britain and Ireland.

The name of Lieut. J. C. MacBryan, the son of Dr. MacBryan, of Box, is in the list of wounded in the recent fighting at the Front. He left the 1st Somerset a year ago to enter the medical profession.

The Council of the University of Sheffield has decided to invite Dr. J. B. Leathes, F.R.S., at present Professor of Pathological Chemistry in the University of Toronto, to accept the Chair of Physiology rendered vacant by the acceptance of Professor J. S. Macdonald of the Chair of Physiology in the University of Liverpool.

The medical arrangements of the new Sheffield University and City Special Battalion have been organised by Dr. Scruffield and Dr. Forbes, and under the control of Mr. W. Swallow. The clerical arrangements were organised by political agents of both the Conservative and Liberal Parties which, Mr. J. S. Skinner and Mr. C. J. Preston, while Mr. A. E. Jameson acted as paymaster.

A base hospital for Leicestershire, containing 500 beds, has been organised within five weeks by adapting the Old County Asylum at Leicester for the purpose. The arrangements have been directed by Major L. K. Harrison, R.A.M.C., who is in command of the hospital, assisted by Major Wallace Henry and Quartermaster G. E. Barfield, with 100 men of the R.A.M.C. Corps and 90 nurses.

(a) Journal American Medical Association.
Of all affections of the lachrymal apparatus obstruction of the lachrymal passages is the commonest, and is perhaps of all the diseases of the adenca of the eye, among the most intractable to treatment. There are two reasons for this intractability, first, the patient neglects to come for treatment until the condition has become chronic, and secondly, the anatomical and physiological arrangements of the parts make it exceedingly difficult to effectually apply treatment.

I will recall to your minds some of the anatomical relations of the structures engaged in the drainage of the conjunctival sac. At the inner extremity of each lid, just at the inner border of the tarsus there is a small papilla, upper and lower papilla lachrymale, surmounted by a minute opening, the punctum lachrymale. These puncta are applied to the surface of the eye-ball, in that area of the conjunctival sac known as the lacus lachrymalis. From these puncta, canaliculi lachrymalis pass inwards behind the caruncle to the sacus lachrymalis, passing at first in a vertical direction for a short distance before turning sharply inwards. The lachrymal sac lies behind the internal palpebral ligament in the fossa sacca lachrymalis formed in front by the nasal process of the superior maxillary bone, behind by the lachrymal bone. From the sac the lachrymal duct passes downwards, outwards and a little backwards, through the bony nasal duct to open into the interior nasal fossa. The mucous membrane of the duct rests upon a submucous tissue containing a plexus of veins, any undue engorgement of which is sufficient to close the lumen of the duct. The mucous tissue lying in the membranous tube thrown into folds, and one fold in particular, more marked than the rest, is found near the lower extremity and called Hasner's valve. The narrowest part of the duct is at the neck where it leaves the lachrymal sac and it is narrowed again at the opening into the nose. This opening is placed obliquely through the nasal mucous membrane. The conduction of tears from the eye is carried out as follows: by the action of the orbicularis palpebrarum muscle during the movement of winking, the internal palpebral ligament is pulled forward, the lachrymal sac being adherent by its anterior wall to the ligament, the walls of the sac are separated from each other, this suspension action draws the tears from the lacus lachrymalis through the canaliculi. But the lumen of the duct becomes greater than that of the canaliculi, it would be expected that the suction would expedite itself in sucking air from the nose up the duct, but this is effectually prevented by the lower opening of the duct into the nose being placed obliquely and acting as a closing valve. Upon the cessation of winking the elasticity of the walls of the sac compress the contents. The contained fluid will pass by way of the least resistance, down the duct, its lumen being greater than that of the canaliculi.

Should an obstruction take place from any cause in the lachrymal duct, the result is that the tears are pent up in the lachrymal sac. They can be pressed back along the canaliculi into the conjunctival sac by pressure with the finger over the internal palpebral ligament. Should the tears remain long in the sac the secretion becomes turbid from the collection of epithelial debris, mucus, dust and foreign matter carried in from the conjunctiva. This turbid secretion increases and distends the sac and becomes the medium for the luxurious growth of bacteria and takes on the characters of mucous-pus. The presence of the material in the sac leads to a catarrhal inflammation of the mucous membrane which still further aggravates the trouble.

This is the condition found in the majority of patients when first seen, and has probably been in existence many weeks and is known as chronic dacryocystitis. There are times when a loss of continuity of the epithelium lining the lachrymal sac occurs, and infection of the mucous and sub-mucous tissues takes places leading to abscess formation. The abscess as a rule points over the sac but the pus may burrow outwards and downwards in the tissues of the lower lid and cheek. This condition, acute dacryocystitis, is always preceded by the chronic inflammation following obstruction. The treatment for this acute condition follows the ordinary rules of surgery for superficial abscesses.

The symptoms of chronic dacryocystitis are, first, epiphora, the tears being unable to enter the already full sac, flow over and wet the cheek; secondly, swelling, immediately internal to the eye, between the inner canthus and the side of the nose; thirdly, regurgitation, mucous pus escaping from the puncta lachrymale upon pressing over the swelling.

After a variable time the catarrhal inflammation subsides and the purulent nature of the discharge ceases, the regurgitated fluid being mucoid only and finally clear.

The walls of the sac after a time become thickened, lose their elasticity from long continued distension, and pass into a condition of atony— the sac remaining distended with fluid even should the obstruction of the duct have been removed, a condition known as hydrops of the lachrymal sac.

Owing to the constant running over of the tears, the skin of the lids becomes excentaneous, and should the epiphora last for a long time, contraction of the skin of the lower lid commences, and will lead to ectropion (turning outwards), of the eyelid, more or less severe.
The presence of a continual mucous-purulent discharge is not only annoying to the patient but a danger to the eye, and is a frequent cause of severe corneal ulcers, and infection of wounds operative or accidental. Every slight erosion of the corneal epithelium, from a speck of dust, may be the starting point of severe inflammation.

The causes of dacryocystitis must be looked for in the obstruction of the nasal duct. This infection may be from either the nose or the conjunctiva. The latter is far less common than the former, but will occur in cases of severe pneumococcal and streptococcal inflammation of the conjunctiva, especially where there is a formation of membrane, and particularly in these classes of cases affecting children. In the majority of cases there is a stricture of the nasal duct and in consequence the events above described follow in due course. This stricture is most frequently at the neck of the sac, less often at the lower end of the duct. It has its origin from some pathological condition of the nasal mucus membrane, conveyed to the mucus membrane of the duct such as chronic rhinitis, and ozena is not infrequently present in dacryocystitis. Ulceration of the nose, even tuberculous or syphilitic, is responsible for many cases, and tumours, particularly polypi, must be added.

The treatment of the condition and its success depends on the length of time it has been allowed to proceed; it is so often that an early case is met with. The discomfort of the continual discharge and often an attack of acute inflammation drives the patient to the surgeon.

If a case be seen early syringing out the sac frequently, with regular application of pressure over the sac to empty its contents, will bring back a healthy condition, provided that any obstruction of the duct has been removed. This may be done in slight strictures and early cases, by passing small medium-sized probes, after dilation of the canaliculus, without suturing the sac. The dilation of the canaliculus should be done carefully until it will take a No. 3 conical probe, which should then be passed into the sac horizontally until its point rests against the inner wall of the fossa saccus lachrymatis and then, keeping its point applied to the inner wall, its direction should be changed to the direction of the duct, that is, downwards, outwards and a little backwards, which is well indicated on the surface by the line of the sulcus between the nose and the cheek. It is never wise to commence probing with the finer probes, as much injury may be done and false passages made if any force is used to overcome obstruction; frequently folds of mucous membrane are encountered in which the point of a small probe will be entangled but which present no difficulty to the larger sizes. It happens sometimes that, after probing successfully with fairly large probes, the point of the syringe is with difficulty passed owing to bands of tissue of the canal and to be withdrawn again and again before its point can be induced to avoid the obstruction. Having passed a probe: through the stricture and left it in a short time, the duct should be syringed through and if the whole duct is open, the fluid will pass into the throat. If this does not occur there is a second stricture below the first that the probe has not passed through, which must be dilated also. To ascertain that the probe has passed through the whole length of the duct and its point rests upon the floor of the nose, a second probe should be laid parallel with the first along the outside of the cheek, end to end, its lower end will indicate the position for the lower end of the probe in the duct, or the point of the probe may be looked for in the nose with the aid of a nasal speculum.

In the other cases the stricture will require lengthy treatment and large probes will have to be passed to counteract the tendency of the stricture, particularly if it is old and fibrous, to contract again. To admit large probes the canaliculus, the lower one, must be slit with a Weber's canaliculus knife. Probing should be done regularly, at least once a week and the size of the probes gradually increased at each sitting, until a No. 10 or 12 is through.

The treatment by probing has to be continued for many months, the patient attending, not infrequently, for a year or more.

When once the passage is free a few drops of 10 per cent. protargol or 15 per cent. argyrol may be applied after syringing.

Finally under certain conditions recourse must be had to operative interference of a radical kind. I refer to removal of the lachrymal sac. This operation may be undertaken for the following reasons: (1) For extensive contraction or obliteration of the duct; (2) where it is impossible to pass a probe or where the passage cannot be dilated beyond the capacity of the finest probes; (3) Where there are changes in the bones, often of a tuberculous or syphilitic nature; (4) in atony of the sac, the walls of the sac having lost all elasticity, and the conduction of tears failing even should an open duct be obtained; (5) similarly in hydrophthalmia of the sac; (6) in those patients who have not the time or inclination to undergo the lengthy treatment of probing; (7) and finally, before proceeding to perform any major operation upon the eye, especially preparatory to cataract extraction. No operation requiring a wound of the eye should be attempted if it can be avoided whilst pus can be regurgitated from the lachrymal sac, for it will assuredly end in panophthalmitis and loss of the eye.

After removal of the lachrymal sac it is not infrequently found that the patient makes no complaint of epiphora, though, of course the drainage passages have been obliterated, and the reason must be found in the small amount of tears secreted. As a matter of fact in normal quiet activity of the lachrymal gland, the amount secreted just suffices to replace that lost by evaporation. Should there be sufficient overflow of tears to cause discomfort, which cannot be kept in check by applications to the conjunctiva and the removal of all sources of irritation, removal of the accessory gland will have the desired effect. In doing this the ducts of the main gland, at least many of them, will be cut across, and the supply from the glands considerably reduced, the lachrymal secretion being supplied through the remaining ducts and by Krause's glands.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by A. H. Tubby, M.S.Lond., F.R.C.S., Surgeon, Westminster Hospital; Subject: "The Treatment of Ankylosis by the Formation of New Joints."
ORIGINAl PAPERS.

THE RESULTS OF RADICAL OPERATIVE TREATMENT OF CANCER OF THE UTERUS.

By THOMAS Wilson, M.D., Lordl., F.R.C.S., Eng., Professor of Midwifery and Diseases of Women in the University of Birmingham.

In a short historical introduction, it was pointed out that in the early eighties, the different forms of amputation of the cervix enabled a five years' absolute cure to be effected in less than 2 per cent. of the cases of uterine cancer that applied for treatment. Vaginal hysterectomy increased the total curability to from 4 to 10 per cent.; the extended operation by way of the vagina, and the abdominal method popularised by Wertheim, have each possible a percentage operability of 45 to 60 per cent., and an absolute curability of 15 to 20 per cent., as claimed in some of the larger Continental clinics.

In this country the abdominal operation is becoming the routine method, because, in the first place, it affords better oversight of the field of operation than the vaginal method; in the second place, because operations by the vaginal route have never been extensively practised here, and thus skill is easier of attainment in a new operation if it is performed by the abdominal method; and thirdly, because only by the abdominal route is it possible to remove the affected glands. This last advantage is likely to prove of increasing value in the future. Many operators in their haste have concluded that it is useless to remove the glands, and have stated that when they are invaded the disease always recurs after operation. Wertheim has, however, published 13 cases in which carcinomatous glands were found, and which nevertheless remained free from recurrence for upwards of five years. For stated reasons the abdominal operation is likely to become more and more generally adopted. It cannot, however, be applied to all cases. The prolonged Trendelenburg posture is dangerous for old patients, for those who are very fat, and for certain women with visceral complications. In such cases the vaginal operation affords a better immediate outlook, and in the old patients especially it is often followed by a long freedom from recurrence.

DIFFICULTIES OF ESTIMATING RESULTS OF OPERATIONS FOR CANCER.

The difficulties of estimating justly the results of any curative method of treatment of cancer are very great by reason of the uncertain course of the disease. In different patients the earliest symptoms make their appearance at very various stages of the disease. The duration of the disease is in the highest degree uncertain; of two women with the affection apparently in the same stage, one may die in a few weeks and the other live for several years. In the practice of the operating surgeon groups of cases, successful as regards ultimate cure, alternate with other groups apparently similar, but all ending in rapid recurrence. All which things tend to show that the actual living virus of cancer, when at length it is discovered, will be found to progress through varying phases of growth and activity, now active and virulent, now stationary or sluggish.

These uncertainties in the course of the disease have been illustrated, and to some extent ex-
paring the total number of cases of cancer that apply for treatment with the number known to be free from recurrence five years later. And even here there are many opportunities for error.

Another important observation that should be, but is not, superfluous must be made: that under no circumstances is it any longer justifiable to publish the mixed results of treatment of cancer of the body and of the cervix. The two varieties should be kept entirely distinct and separately discussed.

In the large German clinics we find that the cases of cancer of the uterus cervix afford a ratio of operability of 45 to 60 and even higher, and an absolute curability of 20 per cent. Wertheim's five-year completed statistics of 450 cases show an operable ratio of 46 per cent., with a primary mortality of 19.5 per cent., and an absolute curability of 19 per cent., 186 of 979 patients being known to be alive and free from recurrence at the end of five years.

In this country, with rare exceptions, the operability is not greater than from 30 to 40 per cent., and the total curability than 10 per cent. The low operable ratio is not due to any difference in the disease, but rather to the fact that the general public and the main body of the medical profession have not grasped the truth that uterine cancer is curable in a large proportion of those cases that apply early for treatment. The consequence of this ignorance is that women do not seek medical aid promptly, and that when they do the necessary investigation is only too often delayed.

The Surgery of Uterine Cancer in Great Britain.

Published papers in the British journals on the extended operation for uterine cancer have been comparatively few, and to a large extent made up of descriptions of technique with occasional suggestions for its improvement. There are no British five-year statistics.

My own work on uterine cancer has been done in the gynecological department of the Birmingham General Hospital. I have taken all the cases applying for treatment in the out-patient department and all those admitted to the wards, and have added all my own private cases. My thanks are due to Miss M. B. Webb, M.D., whose very efficient and enthusiastic help in following up my results I here gratefully acknowledge.

From the year 1896 until December 31st, 1913, there have been 566 cases of uterine cancer. Of these, in 67 the disease affected the uterine body, and in order to clear the ground I deal with these first. Among the 67, 15 vaginal hysterectomies with no mortality, and 29 abdominal hysterectomies with 3 deaths, were performed. The five-year results are given in the accompanying table:

Cases of Cancer of the Uterine Body seen until June 30th, 1909.

</table>

The absolute curability of cancer of the body of the uterus here shown appears small when compared with the rate of 50 to 75 per cent. usually claimed, but I believe the latter rate is based largely on fallacies and small numbers, and will prove to be exaggerated.

Cervical Cancer.

Until the end of 1913, there were 520 cases of cancer of the cervix uteri. These can be conveniently divided into two groups according as operation by the vaginal or the abdominal route was the method of choice. In the first period, lasting until the end of 1905, there were 246 cases, of which 37 were operated upon by the vaginal method with 1 death, and 7 by the abdominal route with 6 deaths. In the second period, from January 1st, 1906, to December 31st, 1913, 274 cases were seen, among whom 20 were operated upon by the vaginal route with no deaths, and 72 by the abdominal with 8 deaths. The total immediate mortality of the vaginal method has been 57 cases with 1 death, or less than 2 per cent.; and of the abdominal, 79 operations with 14 deaths, or 17.7 per cent. The great majority of the abdominal hysterectomies were performed by Wertheim's method.

The ratio of operability has steadily increased; in the years 1896 to 1899 it was 14 per cent.; in the last four years it has been more than 30 per cent.

My total five-year results up to June 30th, 1909, have been investigated and show that, with an increased operable ratio and the adoption of the abdominal method of operation, the absolute curability of my cases has risen from 5.5 to 10.2 per cent.

Results of Vaginal Hysterectomy for Cervix uteri.

Of the patients surviving operation, 16 of 51 = 31 per cent. of the vaginal, and 10 of 23 = 43 per cent. of the abdominal, remained well and free from recurrence for five years and upwards.

It follows from my experience that the final results are steadily improving and may be confidently expected still further so to do. The immediate mortality of the extended abdominal hysterectomy for cervical cancer has fallen; thus, in my own work, in the six years ending December 31st, 1913, there were 6 deaths in 62 operations, a rate of about 10 per cent. The operable ratio has doubled in the last ten years, and may be expected to rise considerably further when the possibilities of the operation are grasped by the profession at large and by the public. The total number of patients remaining free from recurrence for five years and upwards has also increased nearly twofold in the last decade, and we may hope before long with the surgical methods now at our disposal to achieve an absolute curability of 25 per cent. of all cases of cancer of the uterine cervix.
THE DRUG TREATMENT OF DYSMENORRHEA. (a) By J. C. M. WALTER, M.A., M.D., L.L.D., D.P.H.

If we take up any book on "Diseases of Women," and look at the chapter on dysmenorrhea; dust out the platitudes, the theories, the traditional teachings, and the silly superstitions, and come down to the rock-bottom question, what does it teach me to do for the woman who is in recurrent pain, and who refuses to consider any operative measure? There are some vague mumblings about general hygiene, exercise, free bowels, suitable clothing—with suggestions as to a stay in bed, a hot water bottle, perhaps a little broth of potassium or phencarin, and a portentous warning against alcohol or morphia.

My friend, George Bernard Shaw, describes all professions—and especially the profession of medicine—as a conspiracy against the public. Probably he means that we are united for the purpose of enforcing fees for our services. Do we always give honest value for our fees? Does the gynecologist give honest value to the mother when he warns her to give up the glass of toddy, with which she generally will cure her daughter's dysmenorrhea—and substitutes some coal tar compound? The gynecologist promptly says yes—he prevents the girl from becoming an habitual toper; he claims to have saved her from a drunkard's grave, and he thinks his guinea is well earned thereby. Of course this is hooey. Carlyle to the contrary notwithstanding, the number of fools is not great—amongst the class of people who pay fees. What happens in practice is this: the mother, warning from the doctor's draught is not nearly so effective in curing her monthly pains as her accustomed glass of gin toddy, is forthwith filled with a fanatical faith in the virtues of alcohol.

Let me shock you—if obstetricians can be shocked. I believe that if alcohol or morphine cure dysmenorrhea and if we know of no better drugs—then we ought to give alcohol or morphia. Nobody in this neurotic twentieth century has a right to be deprived of relief from pain—or be kept from indulging in the little indulgence, bibi, cito et juvente, simply because there is a possibility of forming a bad habit. This argument, if faced honestly, would wipe, not only alcohol and morphia, but everything that makes life worth living, out of existence.

If alcohol be an effective remedy for amenorrhea, you ought, I submit, to give alcohol without any cant about the fear of making the woman a secret tippler. Observe, I say you ought to give alcohol very—very cautiously to the woman whose patient you take to a stiff glass of punch, some hot port wine, or some gin whenever she has a monthly pain.

You remember that in our superior way we used to sneer at our predecessors, who ordered egg-flip as a prescription under the portentous title of mistura spiritus vini gallici, or who, when they wished to exhibit opium, prescribed a pill described as pilula saponis composita. They were simply wiser than we. They understood the psychology of the prescription. Thousands of women have been seduced into drinking habits by the knowledge of the potency of alcohol as an anaesthetic in amenorrhea, and by their experience of its soothing effects in time of acute unrest, but had the physician been content to order the alcohol as a medicinal draught to such abuse would follow its use, and he would have the credit of devising a real cure for a troublesome ailment. Alcohol in amenorrhea is made much more active by certain essential oils. In some cases the effect of those aromatic oils is simply carminative; in others they appear to have almost a specific effect on the apparatus for menstruation. A convenient form in which to administer these aromatics is the tincture carminativa of the codex. You prescribe about a dram of this in a little hot water every three hours whilst pain exists.

So far I have simply made one point—namely, that the doctor, being satisfied that alcohol gives relief, shall prescribe it, not sub nomine but as an ordinary draught, whose composition is known only to the physician. This is by no means a minor point, for there is much difference between curing a patient yourself and sending her a sharp-pointed curette with instructions how to do the job as there is between prescribing an alcoholic compound as a prescription and direct giving a patient a little wine or whiskey herself.

Most of us will agree, I think, that morphine cures the pain of dysmenorrhea. Most of us declare with horror against its use. I submit that the physician should not hesitate, as often as necessary, to administer it hypodermically himself, taking care to disguise its nature from the patient.

We ought to have a more extended armamentarium of drugs than alcohol and morphine. Next in the order of activity comes phenacetin. It is simply the best of the coal-tar compounds for dysmenorrhea. Do not order it in tablet form, but in separate draughts made up with a little mucilage, carminative tincture, and essence of ginger. Do not give a timorous ten-grain dose, but boldly administer fifteen grains, at least, for the first dose, and repeat it as required. Phenazone is not as satisfactory in dysmenorrhea as phencatin, but may be used where the therapists object to the insoluble powder. Pharmacologists, but in my opinion it is distinctly useful in the cases under discussion. It should not be prescribed alone, but in doses of about four grains, combined with eight of sodium bicarbonate and one grain of caffeine.

I need scarcely touch on the bromides; they have always been used in this disorder, and will always continue to be prescribed; but their tendency is, I think, to depress that excitatory function which is so often wish to augment in those subjects to dysmenorrhea and phencatin.

Of the organic extracts, thyroid, parotid, ovarian and luteal, have been used. The best of these is thyroid. If there be no organic obstruction, such as stenosis of the cervix, and when the ovaries are sound the normal balance of metabolism seems to be restored and the amount and regularity of the flow to become improved. When the abdominal pain has been removed about 10 to 15 grains may be given daily for eight or ten days preceding the date of menstruation.

Belladonna relieves dysmenorrhea best as a suppository—the 1/2 P. belladonna suppository containing about 1 1/2 grains of the extract is quite a potent preparation.

Many gynecologists are inclined to deride
the use of external remedies for this ailment. Some external applications are of distinct value—by far the most active being oil of wintergreen. It is not my business to discuss the theory of its action. It certainly gives extraordinary-relief. It is best applied by painting freely a 30 per cent. solution of oil of gaultheria in almond oil over the affected quadrant of the abdomen every four hours. In more acute cases it may be used with rectified spirits of wine—2 parts to 1 of wintergreen covered with cotton wool. In certain cases about ten per cent. of menthol may be added. It is probable that external remedies are useless as antidotes except wintergreen, menthol, and, perhaps, cocaine.

The only usefully in dysmenorrhea, but only, I think, when applied to the nasal mucous membrane. It is needless to discuss whether there be euritogenic centres in the nose. Every practitioner has noticed a very close connection between nasal affections, especially those of a stenotic or catarrhal character, and affections of the genital apparatus in both male and female. You also find that you can often cure the one affection by treating the other. Of course there is question of a cocaine habit, but quite a weak solution of cocaine, say six to eight grains to the ounce of glycerine and borax applied with a brush to the nares, or used as a spray-diluted with water, is quite effective.

Hot hip baths with mustard and turpentine stipes are always admirable, but only as convenient methods of applying heat and counter-irritation.

Some people sneer at the list of about fifty drugs, which a certain treatise on treatment gives for dysmenorrhea, but there are obscure cases which baffle even the special treatment selected from a wide range of remedies. Gelsemium, either alone or with croton chloral, is excellent in neurotic and neuralgic creatures. I think chloral hydrate is specially indicated in the dysmenorrhea of the florid and full blooded. Fifteen grains of it, with as much bromide of potassium, and as many minims of tincture of gelsemium given in chloroform water every three hours when required, is a splendid treatment. For the gelsemium about a drachm of succo hyoscyaminii or their minims of tincture of sem. Stramonii may be substituting. Apioi seems to be getting into disrepute and valerian regaining confidence. I have given both drugs pretty freely, and think apioi of most use where scantiness is the major trouble, and valerian where the spasmodic paroxysmal pain predominates. Viburnum prunifolium is probably of more value where the dysmenorrhea is due to affections of the uterus, rather than the tubes or ovaries. Certainly it seldom fails to relieve when given with phenaetin and bromides, but one is doubtful to which of the drugs the credit is due.

I have omitted ergot from the category so far, because although one often orders it with apparent advantage, one hesitates to say that it is a drug which can ordinarily be prescribed with confidence and safety.

Let me finish with an old-fashioned remedy, but one of real merit—asafoetida. Despised by many is an old woman's case, its penetrative volatile constituent seem to have an almost specific effect on the ovaries, and though perhaps too stimulating in some cases it is very useful where dysmenorrhea is due to sluggishness of function.

SAN REMO AS A WINTER HEALTH RESORT.

By PROF. H. KRAUSE.

The number of health sanatoria of various kinds, which started some few years back, especially in Germany, increases from year to year, and the specialisation of such establishments, equipped with the most modern requirements, is being continually developed. Consequently those health resorts, whose benefit depends chiefly on their climatic surroundings, begin to struggle hard in the general competition. Winter resorts, too, a growth of the last ten years, have proved a great attraction to the exercise-loving members of Western Europe, and will continue to attract many of those who formerly in the colder months sought the comforts of the Sunny South. Thousands of people, who formerly used winter by winter to frequent the southern watering-places, now satisfy their craving for open air and healthy exercise in the highlands of Switzerland and the Engadine. Still a considerable number of winter travellers cannot resist the charm of the Riviera climate, and the only reason to account for this is the incomparable attraction of the winter sun, which, combined with the warming properties of the Mediterranean, fashions, as it were, from the winter a sub-tropical vegetation and transplants the traveller, after quite a short journey, from the grey, austere northern atmosphere to the verdant beauty and charm of spring.

However, we do not wish to speak of the crowd who throng to such places in quest of pleasure or amusement, but of the weary and heavily burdened, to which either the sanatorium or climate or both are to bring renewed health and vigour. Sanatoria have of late years gradually changed from a general to a highly specialised type, the various climatic resorts differing from each other in many respects, such as the humidity or density of the air, wind force and mean temperature, each having in consequence a different therapeutic value. Nearly twenty years have gone by since Leyden at the International Medical Congress held at Moscow introduced the following words:—

"The time has come when the homes of our tubercular patients no longer bleach in the cemeteries of the Riviera: the poor sufferers can die at home." From this followed the introduction of the many highly organised tuberculosis establishments, which now exist, and based on these models other sanatoria have been founded year by year for other diseases, in which the patient can reckon on finding competent doctors and meeting with all possible care and comfort, especially if the case is a surgical one, requiring several weeks or months of treatment.

The situation is, however, different in many chronic cases, which may last for years. Doctors no longer require patients suffering, for example, from diabetes, tuberculosis, tabes—if they have the necessary means, to remain for years of their lives in sanatoria; indeed, most of the sufferers would be unwilling to do so. For such cases a sanatorium in our day is a hygienic, dietetic, and school, which sometimes doubtless accomplishes the process of healing, but more usually merely prepares or introduces it by bringing before the
patient in a permanent way the particular conditions of life which suit his particular case. When he has passed through this course of schooling, which in the less severe cases may require but a short time, the important question presents itself to the physician, whether a further stay, although advantageous to the disease itself, may be harmful to the patient's psychical state of mind. No experienced medical man, especially in chronic diseases, underrates the force of moral resistance. A healthy man according to his needs and means is allowed to choose for himself his place of life and environment, and the same principle, as far as possible, should be conceded to the invalid.

Authorities are beginning to declare against a too lengthy stay in a sanatorium, and in suitable cases shorten the period of isolation and advise a return to normal professional life: even in less favourable cases a release from strict discipline is often thought advisable and time and opportunity are afforded to the patient to put into practice the self-control and mode of life which he has been taught in the sanatorium.

When the time for this change of treatment comes, the patient turns instinctively to the South. Even in plant life this yearning for light and sun manifests itself, and the physician would be wrong to oppose it on principle. The mere number of medical men themselves, who seek and find renewed health and strength on the Riviera, will force him to renounce his opposition. How many of my colleagues have contended as much to me: they have found it for themselves and they will hand on the discovery to their patients.

I myself have the daily opportunity of observing that under the influence of the Riviera climate the effect and processes of medical treatment are so much quicker and more favourable, and I can no longer doubt that this climate possesses in a very high degree a stimulating power, which extraordinarily hastens the cure. Nor can we be surprised at the astonishing number of reports made at the Congrès International de Thalassothérapie de Cannes, 1914, on the enormous curative effects of the cure sea, that have been treated in cases of pulmonary tuberculosis and diseases of the bones, states of weakness, maladies of heart, nerves, anæmia, nephritis, &c. I have made a few but very satisfactory experiments in sun-treatment, and now can mention with pleasure that a helio- or surgical cases has recently been opened at San Remo in a favourable situation close to the sea: this contains big glass-covered verandas for helio- and orthopaedic gymnastic apparatus. Comparing the favourable accounts of French doctors with my own experiences of the Riviera climate and the successful treatment of many patients in San Remo, I maintain that in certain categories of diseases it is of the highest importance to give a thorough trial to this method. Especially favourable results are obtained in the treatment of weakness and convalescence, anæmia, neurasthenia, arterio-sclerosis, diseases of the heart and blood-vessels, chronic nephritis and surgical tubercular exudations. My personal experiences are more immediately concerned with affections of the upper air-passages, catarrh of the middle ear, asthma bronchiale nervosum et catarrhale, and neurosis of the respiratory and circulatory organs, tuberculosis of the lungs and throat. The treatment of these I have always found a great and welcome aid in the climate of San Remo. Its desiccating property is well known, which most efficaciously promotes resorption through the dryness of the air, the evaporation of its exceptionally salty sea-water, and the radiation of its ever-present sun. In San Remo I have been better satisfied with the course taken by many even advanced cases of diseases of the larynx than in the ungenial climate of the north: not rarely small (?) excisions suffice to introduce the resorption of external sinuses and promote the cicatrization of ulcers. It may be admitted that in such cases, favourable social conditions, different surroundings, complete rest have their influence, but a remainder is always due to the climate alone. In San Remo, too, less severe cases of lung trouble react satisfactorily, especially where weakness of the heart is an aggravation. In my opinion this weakness of the heart represents a very special indication for the choice of the San Remo climate. A large number of cases have been sent to us from sanatoria of the plain and mountain, which have been very favourably influenced here. Whether this amelioration has been caused by augmentation of the red cells, hemochrom and hematin, due to the influence of the sea, and attested by trustworthy observers, or has been due to the strengthening of the heart muscle by the mild sea air, or to the easier and more extensive respiratory and circulatory action, or to the co-operation of all these phenomena, I cannot say, but in any case the patient's respiration deepens, appetite and weight increase, infiltrations become clearer and disappear, coughing and expectoration lessen. Similar observations have induced Professor Torianini, of Pavia, the famous inventor of the artificial pneumo-thorax, to make San Remo a residence for his patients, his successful treatment of whom is so universally recognised.

Particularly worth mentioning I think are my observations on bronchial asthma, which I have had to now treat according to the principles given in my pamphlet "Zur Therapie des Asthma bronchiale" (Therapie der Gegenwart, July, 1913). Proceeding in this way, particularly in cases of nervous asthma, I found (?) the psychical therapy confirmed, and this was combined with the ascertaining and removal of the special causes (e.g., respiration through the mouth, affections of the nose and pharynx, digestive troubles, vagotomy, &c.). Moreover, the asthmolysin, mentioned in my pamphlet, has proved an excellent nerve-stimulant, but in minimum doses prophylactically: it undoubtedly renders superfluous the abundant use of narcotics. But here, too, we must not overlook the part which the climate played in the treatment. I have certainly found it easier in San Remo than in other resorts to cure the complicating neurasthenia and catarhal symptoms. The deciding factor in a permanently successful treatment of asthma is not this or that medicament, this or that surgical operation, but the invigoration of the mental and bodily energies of the patient struggling against the causes which provoke the disease.

For such patients I find in San Remo two well-managed health establishments at my disposal, the Villa Azzurra (Dr. Fischetti) and the Bellevue
THE ROLE OF TUBERCULIN IN TUBERCULOSIS. (a)

By NATHAN RAW, M.D.,
Physician, Mill Road Infirmary, Liverpool.

In this short note I must confine my remarks purely to the pathological aspect of tuberculin and its general bearing on the treatment of tuberculous infections.

In order to understand the effects of tuberculin when injected into the human body, it is necessary to briefly refer to the varieties of tubercle bacilli and their influence in producing varying lesions in the human.

Originally of a common species, it may reasonably be assumed that long environment has resulted in three distinct types:

1. The *typhus humanus*.
2. The *typhus bovinus*.
3. Avian bacilli.

THE PREPARATION OF TUBERCULINS. (b)

The various "tuberculins" are preparations from tubercle bacilli, or from the media in which they have been grown. Koch introduced his first tuberculin in 1890, long before the specific treatment of chronic infections by injections of bacterial emulsions became general. The main varieties of "tuberculin" may be regarded as marking stages in the progress of Koch's investigation.

Koch found that the injection of sterilised cultures of tubercle bacilli, even in considerable quantities, into healthy guinea-pigs produced only local suppuration; in tubercular guinea-pigs very small amounts of the same preparation caused death. By the methodical use of high dilutions, so that the doses given produced no violent reaction, the tuberculous process was apparently arrested. Koch observed, further, that emulsions of bacilli (in the quantities he used) remained unabsorbed at the site of injection and caused suppuration. From this he argued that the curative constituent must be soluble. Thus originated the tuberculins containing those constituents and products of the tubercle bacillus which are soluble in the medium (gycerin-veal bouillon) in which it is grown. For their preparation the organism is grown for six weeks as a film on the surface of the broth.

By merely filtering off the organisms from the six weeks' culture the two bouillon filtrates commonly known as T.O.A. (Tuberculin original air, prepared with a bacillus of human origin) and P.T.O. (Perlsucht Tuberculin original, from a bovine strain) are obtained. These are the two tuberculins, and are, for that reason, now used by many workers at the commencement of a course of immunisation.

OLD TUBERCULINS (T. and P.T.).

The tuberculin first introduced by Koch, however, was a concentrated preparation made by evaporating the six weeks' broth culture to one-tenth of its volume, and filtering. This preparation, commonly known as "old tuberculin," also exists in two varieties, made respectively from human and bovine strains of the bacillus, the latter being distinguished as Perlsucht Tuberculin (P.T.). This old tuberculin was introduced into therapeutics before the experiments necessary to determine the proper dosage, frequency of administration, etc., were complete. The result was disappointment and, in not a few cases, disaster. The treatment fell for the time into disrepute, and in Great Britain, at any rate, was practically abandoned until within the last few years. As an aid to diagnosis, however, tuberculin continued to be used, and for this purpose old tuberculin is still the preparation always employed.

The old tuberculins and bouillon filtrates may be classed together as "exotoxic" tuberculins, as distinguished from the "endotoxic" preparations, also called "new" tuberculins.

NEW TUBERCULIN (T.R.).

Meanwhile, Koch was experimenting with a view to the production of a tuberculin which should produce immunity to the bacilli themselves, since he had come to the conclusion that old tuberculin immunised only against their soluble toxins. The following process is that which he adopted to secure this. Young and highly virulent cultures are dried in vacuo and then ground in an agate mortar until the microscope shows no intact bacilli. Distilled water is added, and after thorough mixing, the suspension is centrifuged. The upper layer, an opalescent whitish fluid called by Koch T.O. (Tuberculin Oberschicht), is decanted off and discarded. The deposit is again dried, ground, treated with distilled water, and centrifuged. The supernatant fluid from this and subsequent similar extractions is kept, the process being repeated until no deposit remains. The successive extracts, with the exception of the first (T.O.), are mixed, glycerine to the extent of 20 per cent. is added, and the fluid is made up to such volume that each c.c. corresponds to 10 mgs. of the dried bacilli with which the preparations started. Apparently, however, only a portion of the original bacillary substance reaches the final product, since the latter, known as T.R. (Tuberculin Rückstand), is said to contain only about 2 mgs. of organic solids per c.c.
NEW TUBERCULIN (B.E.).

Working on the subject of agglutination, Koch found that the agglutinating power of the blood was increased more rapidly by injections of dead tubercle bacilli than by T.R., and was thus led to devise still another immunising preparation, bacillary emulsion (new tuberculin, B.E.). This consists of an emulsion of one part of dried pulverised tubercle bacilli in 100 parts of distilled water, to which 100 parts of glycercine are added. Bacillary emulsion is analogous to other vaccines consisting of sterilised emulsions of bacteria, and may be supposed to act in the same way. As compared with T.R., it has the advantage of requiring a much less difficult and complex process of preparation; in the doses now in use it has not been shown to be inferior in other respects. It is used for curative purposes.

In my endeavour to find if it was possible to protect animals from an acute infection by means of tuberculin, I inoculated twelve guinea-pigs and rabbits with large doses of human and bovine tuberculin, leaving them for three weeks and then injecting small doses of tubercle bacilli of the opposite strain to the tuberculin used.

In no case was I able to produce a complete immunity, although I thought that the infection was not so virulent and did not tend to progress.

Other observers have obtained the same results, so that I think we are justified in our conclusion that by means of tuberculin only we are not able to completely immunise an animal against infection, even for a few weeks.

With regard to the cultural appearances of the different strains of bacilli we have to admit that they are not constant. After having made some hundreds of pure cultures of all types, I am not at all certain of picking out the individual strains in many instances, although as a general rule one can do so.

The cultures which I show to-night are fairly typical of their type, but some intermediate types, as described by the English Royal Commission, are sometimes met with.

It comes to this, then, that we have not yet in our possession any certain method of distinguishing accurately the precise nature of a tuberculous infection, hence we cannot accurately decide whether certain lesions are of human or of bovine origin. I hope that soon our cultural and bacteriological methods will be so improved as to decide this important question.

In the paper which I published in the British Medical Journal in 1907, I ventured to suggest that a considerable amount of tuberculosis in children was caused by the bovine tubercle bacillus. Since that time a great amount of scientific investigation has been carried out over the whole world, and especially by our own Royal Commission, with the result that we are now certain of the following conclusions:—

1. That the great mass of tuberculosis, occurring in the human subject in the form of pulmonary tuberculosis, is caused by the human bacillus (typus humanus), and is conveyed from person to person by infection.

2. That a considerable amount of so-called surgical tuberculosis in children and adults is caused by the bovine bacillus (typus bovis) received into the alimentary canal through milk and food.

Originally of a common species, the bacilli have, owing to long environment in different hosts, assumed marked characteristics, so that we are able, experimentally, to divide them into two types:—

(a) Bacilli of the typus humanus, which cause:
   (1) Pulmonary tuberculosis and pleurisy.
   (2) Secondary tuberculous enteritis.
   (3) Tuberculous laryngitis.
   (4) Fistula in ano, and possibly some other lesions.

(b) Bacilli of the typus bovis, which cause:
   (1) Primary abdominal tuberculosis.
   (2) Tuberculous lymph glands.
   (3) Tuberculosis of bones and joints (probably).
   (4) Genito-urinary tuberculosis.
   (5) Acute miliary tuberculosis.
   (6) Lupus. Meningitis.
   (7) Pulmonary tuberculosis (a small percentage).

I have for the last twelve years separated my wards in hospital into human and bovine wards, and after an observation of over six thousand cases of tuberculosis, I am impressed with the fact that it is rare to see lesions of the human and bovine type associated in the same patient. In fact, they seem to be antagonistic to each other, so that one rarely observes a patient suffering from pulmonary tuberculosis develop any other lesions beyond those mentioned in the human group. It is also rare for cases of gland or bone tuberculosis to develop true pulmonary tuberculosis except in the course of a general systemic infection.

It is necessary to mention this clinical fact to explain my reason for using tuberculins of the opposite strain in the treatment of the disease. There seems to be little doubt that a mild infection by bovine bacilli in the human body, such as neck glands, by way of the alimentary canal, will protect against an infection by human bacilli, and it is most probable that a large number of people are immunised against pulmonary tuberculosis in after-life by having been infected in early childhood by bovine bacilli through milk or food. In all the experimental work throughout the world it has been found to be a rare occurrence to find both types of bacilli in the same body.

VARIA TIONS IN VIRULENCE.

Whether or not a patient is going to be destroyed by tuberculosis seems to me to depend on two important factors:—

1. Virulence of infection;
2. Individual resistance.

The variability in virulence of the tubercle bacillus is well recognised. In many cases, fortunately, the injection shows little tendency to progress in the body, so that we constantly see in practice patients who have suffered from tuberculosis for twenty or thirty years. In other cases, the injection is virulent and rapid, and kills the patient in two or three weeks.

In the former cases the bacilli are of low virulence; in the latter they are highly virulent, giving the body no chance to offer any resistance to the attack.

TREATMENT BY TUBERCULIN.

It is in the avirulent bacillary infections that tuberculin is of such great service, and I have found it of little or no value in acute virulent infections.

The whole object of treatment by tuberculin is to produce an immunity in the blood against infection by tubercle bacilli; and, what is even more important, to prevent the further spread...
of the bacillary infection in the tissues. Whether or not it is possible to ever produce a complete lifelong immunity against tubercle is a matter of doubt.

As a result of my experience, I have found that the lesions in the body which are caused by the \textit{tubercle bacillus} are benefited more quickly and certainly if a tuberculin prepared from the opposite strain—namely, bovine tuberculin—is used; and in all cases of pulmonary tuberculosis I now only use bovine tuberculin. It is less toxic, and does not so readily cause reaction, is more easily tolerated, and causes the lesion to disappear from the sputum more quickly. For the lesions caused by the \textit{tubercle bacillus}—namely, lymph glands, tuberculous peritonitis, lupus, tuberculous disease of the bladder, bones and joints—I invariably use Koch's old tuberculin prepared from human cultures.

The question of dosage is of vital importance, and my routine practice is to administer a course of tuberculin in twelve weekly injections, then resting for a month, and, if necessary, repeating the maximum injection every week. My dosage is as follows, of either human or bovine tuberculin:

<table>
<thead>
<tr>
<th>Dosage</th>
<th>mg.</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0001</td>
<td>0.001</td>
</tr>
<tr>
<td>0.0002</td>
<td>0.004</td>
</tr>
<tr>
<td>0.0004</td>
<td>0.008</td>
</tr>
<tr>
<td>0.0006</td>
<td>0.010</td>
</tr>
<tr>
<td>0.0008</td>
<td>0.015</td>
</tr>
</tbody>
</table>

A special watch must be kept on the temperature, pulse and blood. It is rare to observe a general reaction if the above dosage is carefully followed.

In a great many cases the tubercle bacilli disappear entirely from the sputum at the end of a course of injections, but, unfortunately, if the tuberculin is not persisted in they in many instances speedily return; so that in some cases of pulmonary tuberculosis the injections should be continued for an indefinite time.

Whilst tuberculin \textit{per se} cannot be expected to heal cavities in the lung or replace damaged tissues, yet it undoubtedly has the power of preventing the spread of the tubercle to healthy parts by means of its immunising effects. Time is thus given for repair of the affected tissues.

In conclusion, I would like to express my opinion, after treating over a thousand patients with injections of tuberculin, that it is a remedy of the greatest value, especially in early cases and where the deposit of tubercle is localised, as in one apex or in a lymph gland or single joint; but where the tuberculin is disseminated and complicated by secondary infections, the use of tuberculin cannot be expected to be of much avail. It ought, however, to be tried in every case with the hope of some relief or possible benefit, as we cannot allow the patient to suffer and die without making every effort to arrest the progress of the disease.

Tuberculin is not going to revolutionise the treatment of tuberculosis. It is a valuable aid to the other methods of treatment, hence it must be used with care and discrimination and with a full knowledge of its dosage and therapeutic effects.

I would conclude by saying that the best treatment we can offer to-day to a person infected with tuberculosiis is a prolonged open-air life, preferably in a well-conducted \textit{sanatorium}, excess of nutritious food, gentle exercise followed by plenty of rest, and a course of tuberculin by a careful physician.

**THE HOUSING OF THE WORKING CLASSES—STANDARD OF AN HABITABLE HOUSE IN TOWN AND COUNTRY.** (a)

BY A. B. DUNNE, B.A., M.B., B.C. CANTAB., Barrister-at-Law, etc., Medical Officer of Health for Doncaster and Rotherham.

The question of a standard of an habitable house is one which must have presented itself to most medical officers of health when called upon to discharge the duties under Section 20 of the Housing of the Working Classes Act, 1860.

I propose to limit my paper to a consideration of the standard applicable to houses inhabited by what may be broad ly termed the working classes. The question of a standard for new houses both in town and country presents no essential difference, although subject to modification by locality, type of workmen to be housed, rate of wages, etc.

Another point, and in my opinion a very important one, is what standard should be applicable to existing houses? This raises issues in which "the personal equation" of the individual medical officer of health must of necessity play an important part, and still more so that of the local authority.

Let us first of all direct our attention to the standard which is required for a house to be occupied by the regularly employed artisan or collier. For the less fortunate workman in the towns and the agricultural labourer a cheaper class of house is required, simpler and more restricted in its conveniences.

I have recently been interested in a scheme for housing the working classes initiated by the urban district council of Bentley, which may be regarded as a typical modern mining community. A type of house is designed to let at 7s. per week clear. A description of this class of house, designed by the council's surveyor, Mr. R. G. Whitley, for the accommodation of artisans and colliers, well illustrates the standard of an urban working man's dwelling.

The ground plan shows living room, scullery, food-store, coal-place, and closet; on the first floor there are three bedrooms. There are no outbuildings or projections from the main buildings, all are under one roof. The living-room is 12 ft. by 12 ft., 6 ins. clear, and scullery 11 ft. 6 ins., with copper, sink, and bath provided. A w.c. is placed in a closet, access to which and the coal-place is from the recessed porch of the back entrance.

There is a recessed porch to the front door. A food-store 6 ft. by 2 ft. 2½ ins., which ventilates directly into this porch, is provided alongside the living-room. A staircase 2 ft. 8 ins. wide leads directly out of the living-room, and is placed over the coal-store and closet.

The first floor contains three bedrooms as follows: No. 1, 12 ft. 6 ins. by 10 ft. 3 ins.; No. 2, 11 ft. 6 ins. by 9 ft. 6 ins.; No. 3, 9 ft. 6 ins. by 7 ft. 6 ins. All the bedrooms can be entered directly from the landing, and are provided with fireplaces, with the exception of No. 3. The frontage of such a house is 18 ft. 6 ins., and the depth 23 ft. 10½ ins., and are intended to be erected in blocks of six houses with a common garden.\(^1\)

---

1. Paper read at the Congress of the Royal Sanitary Institute Blackpool, July 6th to 11th, 1914.
It will be noticed that no "hall" or "parlour" is provided. Such, then, is a standard house for, if one may so call him, a standard workman with a standard family. A few general observations are necessary. I take it that any dwelling intended for permanent occupation must be built of bricks for permanent occupation must be, and the currency of the building trade may term them. So far as I am aware, no cheaper form of material has successfully established its claim to supplant them.

**Site of Dwellings.**—Much of the present despicable state of the housing which we now enjoy is due to the fact that any place was thought good enough to build a house upon, and to a certain extent the same is true to-day. Therefore, one of the most useful provisions in any town-planning scheme is that which enables the local authorities to determine what parts of an area are to be allotted to dwelling-houses, factory sites, etc. Much lowly and otherwise unsuitable land for building-houses upon will thus be ruled out. Now that the value of direct sunlight is becoming more appreciated, there is additional reason that the living-room should have a south-east or south-west aspect. The minimum accommodation required resolves itself into the question of individual requirements and wages; but, apart from this, what should guide an authority in designing a house?

Having visited many workmen's homes, I am of opinion that a large sunny living-room, at least 14 ft. by 12 ft., is a sine qua non, and my opinion has been confirmed by answers I have received from housewives whom I have questioned, as well. It has been argued that another room or parlour should be provided; that the husband or young couple must be thought of. My answer is that the claims of the housewife come before the husband, and that the young couple will look after them, themselves. What use is a parlour in most cases? I have more often than not found them unfinished, or used to store the bicycle or pram in; sometimes let off to another family, or used as a bedroom for a lodger. The choice lies between a large, cheery living-room, with plenty of elbow-room, and a cramped living-room and a pokey parlour.

Is a "hall" required? No. This cannot be without sacrifice of valuable space which can be better utilized in the general living-room, than being wasted by being cut off as a dark, narrow passage, which leads to a front door seldom, if ever used.

Of what material should the floor of the living-room be? Much may be said for a board floor, but this presumes sound, seasoned wood, and good honest workmanship. A board floor is hard to keep clean, often harbours filth, and is much more difficult to scrub than a tiled one. I am myself in favour of tiles or "quarries" set in cement. Few will deny that one's own kitchen thus floored is amongst the cleanest and most comfortable of rooms. Ask a woman's opinion, which is easy to keep clean, and she will say a tiled floor. This floor is dry, clean and durable.

A good closed range is both economical in cooking and cleanly, and has this advantage over an open or Yorkshire range, that more than one pan at a time can be used for cooking. An essential in a living-room is the provision of one or more large cupboards. A good scullery is the necessary essential. I have presumed that water is laid on over a glazed earthenware sink provided with a large hardwood drainage board. A copper should be provided fitted with a galvanized iron cover, so arranged as to permit the steam to escape up the flue, easily. Lastly, there should be provision with both hot and cold water laid on, and should have a hinged lid to cover it when not in use. Much amusement has from time to time been aroused by tales concerning the uses to which the bath has been put. I have made it a point to examine as many baths as I could, and have not up to now found any rabbits or boxes of bedding-out plants kept in them. I think too much has been made of the misdeeds of tenants.

Is a water-closet an essential? In a house such as I am describing, erected in a locality where there is a public water supply and disposal system, a pedestal water-closet is an essential. Between the water-carriage system and any other, at all events as regards urban communities, "the verdict of the stricken field has been given," to use a picturesque phrase of the Lord Salisbury. The w.c. is placed in a closet which is isolated from the house by the rear recessed porch; this arrangement allows of a greater degree of privacy, and permits of a backyard unobstructed by outbuildings, an important matter when the washing is done at home and the clothes have to be hung out to dry in the backyard.

**The Foodstore or Pantry.**—This very essential provision has hardly received the attention which it deserves. At the Congress at York a very instructive paper was read on the subject which was regarded by me as a model. The foodstore in the past has been an after-thought, but I have noticed in the new colliery village houses that very satisfactory ones are provided; in fact, more so than in my own house, which is of the understairs type.

The ideal foodstore is on the ground floor, with one wall an outside one at least. It need not necessarily be large, as food is not bought and stored in large quantities nowadays, but it should be cool and well ventilated directly to the open air, and should not be placed under the stairs. A cold slab is a very useful adjunct. A space of 6 ft. 3 in. will usually be quite sufficient.

How many bedrooms should there be?—For the proper separation of sexes, which now is impossible in many houses, three bedrooms should be provided. In fact, the question of bedroom accommodation ranks along with the living-room as the two important questions in housing. As the usual size of beds are, double 6 ft. 6 ins., and 4 ft. 6 ins., and single 6 ft. 6 ins., and 3 ft., two of the bedrooms should be of sufficient size to accommodate a double bed. The larger will usually be occupied by husband and wife, and should in addition be able to take a small bed or cot for the little one. A room 12 ft. 6 ins. by 10 ft. 6 ins. by 8 ft. will do this comfortably.

The bedroom window should not be less than one-tenth the floor space; this, in my opinion, can with advantage be increased. Let me put in a plea for the sash window, a simple room to be more conveniently ventilated than by one of the casement type. The latter, with their cheap fittings, soon get broken and out of order, and then the window is seldom opened. The third bedroom should easily accommodate a single bed, but as single beds are but rarely used by the working classes, it were better that this room should be designed for the use of a double bed. All bedrooms should have a fireplace, but in the type of house we are considering it is usually impracticable to provide fireplaces in all three bedrooms. A ventilating opening must be placed in the outside wall.

**The Back Yard.**—Experience leads me strongly to urge the asphalting of the whole of it. In theory, to reserve the open part of it for flower beds is all very well, but in practice all uncovered earth soon becomes trodden down, and then soaked and soddened with tea-leaves, scraps of broken food, potato peelings, etc. Therefore, an
asphalted back yard is an essential, as thereby alone can it be kept clean and sanitary. Finally, sanitary dust bins should be provided. The walls of which a tins supplied are too small in most cases to contain the week's household refuse. Unfortunately, these tins soon get knocked about and worn out, and the lids lost, though fastening them by a chain to the house wall will obviate this. A back yard common to a block of houses should not be countenanced. It is a fruitful cause of untidiness and about everybody's business to keep is nobody's. The rule should be every house its own back yard.

When we consider the standard of a habitable house for the poorly-paid worker in the town and the agricultural labourer, we are at once faced with the difficulty that the average weekly income of the former may never reach $25, and in the latter rarely $15, or $20. How can these afford to pay, keeping in mind the expense of rearing a family and the enhanced cost of living? I certainly think that 4s. and 3s. a week are the utmost that can be asked, any more is at the risk of bringing up a semi-starved and impoverished population. Can houses be built to let within these rentals, and of what material? Shall there be a wall without minimum room accommodation? It has been suggested that the £100 cottage will solve the difficulty in the agricultural districts. Will it? I have my doubts, which I have confirmed by the account that I have read by Dr. R. W. C. Pierce in his annual report for 1915, to the Guildford rural district council on the cottages built by Mr. St. Loe-Strode.

The labourer is worthy of his home, which must be soundly built of durable materials, plain in character, and necessarily shorn of some of the conveniences and amenities found in the urban workman's home. To mention one in particular, a bath. At the church congress at Southampton last year, Lord Salisbury said that the agricultural labourer did not want one; his lordship's statement was warmly traversed. There are conveniences now lacking in many rural cottages which might well take precedence of a bath. How about a copper? It does duty for both purposes in thousands of homes. I should certainly prefer a copper to both any day. A boiling and the cottage housewife has my sincerest sympathies when she has to boil the weekly wash in the pot over the open kitchen fire.

As water will rarely be laid on, a well-designed privy should take the place of a w.c. Even for houses under the rank of the country mansion, an experience of country rectories in several dioceses has led me to maintain the opinion that there is much to be said for the advantages of the earth closet over the w.c.

Finally, as my paper would run into several appendices, I must conclude with a few words on the standard of habitability of existing houses. What provision is made, one in arriving at the conclusion that a dwelling house appears to be in a state so dangerous or injurious to health as to be unfit for human habitation? Local authorities are apt to take a different view from their professional and statutory advisers as to the grounds on which the representations are based. Briefly, I would such houses are existing alone in such a marked degree or in conjunction with other, as would support such a representation:

1. Dampness in living rooms of old houses, due either to walls built without damp courses, or of very hygroscopic materials, such dampness rising up the walls to a considerable height, or extending over a large area, and persisting even in dry weather.

2. No through or sufficient ventilation. Amongst such dwellings I would include those houses which are built " back to earth," where the adjacent earth reaches a high level, and back to back houses, so common in the northern towns.

3. General dilapidation after which I include cottages with walls perished, roofs leaky, rafters rotten, bedroom floors sprung and unsafe, and broken tiles laid on earth.

4. The hopeless cases, for instance, dwellings which have been improvised out of old malt-kilns, barns, cart-sheds, and other miscellaneous buildings.

In conclusion, I feel that I have merely touched on the fringe of the question, but what I have said has been prompted by an experience of the actual conditions under which numbers of our fellow-countrymen, their wives, and families are living. The fortitude and patience of the women under the often adverse circumstances of their homes are admirable, and in their devotion to their homes and their children they put to shame many mothers in better circumstances. The cleanest and brightest home I was ever in was that of the wife of an agricultural labourer; in others respects it was quite as remarkable: it was merely formed by a portioning off of a cottage, a corner of the kitchen, approached by an almost perpendicular ladder, was the space between the tiled roof and the living-room ceiling.

Standards are of little use unless efforts are made to reach them. The question of housing cannot remain as it is, touching as it does the most homogeneous classes of our population in their daily lives. The public elementary schools have inculcated a higher standard of living amongst the people, and what the present adult generation will tolerate their children will not; cui bono to teach the girls housewifery and cooking in our schools when the lessons there taught are to be nullified in the home.

The future well-being of the nation depends in a large measure on the satisfactory housing of our industrial population.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

EXOSTOSIS OF THE TIBIA.—Mr. Willmott Evans operated on a boy, at 14, who had been admitted complaining of a swelling on the inside of the knee. The history was that the swelling had been noticed there for the last three or four years; it never caused any pain, but was steadily increasing in size. On palpation the swelling was felt to be hard and to be attached to the inner side of the upper end of the tibia; the skin was not attached to it. The swelling was evidently slightly pedunculated. A diagnosis of cancellous exostosis was made, and an operation for removal was advised.

The boy was anaesthetised, and an incision two inches in length was made over the swelling. This was deepened until the surface of the tumour was seen. It was found to be capped by a bursa. By means of a chisel and a mallet the bony pedicle was cut through and the tumour removed. Bone forceps were employed to smooth the remnants of the pedicle. The deep fascia was stitched together and the skin wound closed with Michell's clips. An aseptic dressing was applied.

Mr. Evans said there are two varieties of exostoses—in the one the bony swelling consists mainly of cancellous tissue, but on the most superficial part there is a thin layer of cartilage which grows on the surface, while the deeper part is converted into bone, so that this tumour may be regarded as an osseous chon-
Dr. VITTOZ’S EXERCISES FOR DEVELOPING MENTAL CONTROL.

By Miss Hilda Wigram.

I.

Dr. Vittoz’s mind-training is based on the fact that he believes he has discovered a system of muscular vibrations, by which the state of mind of the patient can be shown to the physician. He places his hand on the patient’s forehead, and by means of these vibrations, which he feels, he can diagnose the patient’s mental condition.

This is because of the fact that, as it enables him to find out the mental habits of his patient in an hour or two, whereas it would take the ordinary physician days of careful observation to make these same diagnoses. It is not, however, likely to be of practical importance, and the hand sufficiently sensitive needs careful and patient practice, and it is hardly probable that we shall find medical practitioners able and willing to devote time and attention to such a side branch of psychotherapy. Since there have been somewhat one-sided criticisms of Dr. Vittoz’s exercises and system, I propose to deal with a few special points in his training, the value of which appear to have been overlooked.

His system divides itself naturally into two parts:

I.—The exercises from the point of view of diagnosis.

II.—The system of education and training of the will.

I. I will take first the few that Dr. Crichton Miller quotes in his interesting article on the re-education of attention and control of habits. (1)

(1) Figures of eight or ∞.—The value of this consists in the regular attention without break that it necessitates. Many patients can with ease put up mentally figures, letters, etc., but cannot make a ∞ or ∞. Spaces occur in the figures, in which case the physician may be sure that the patient has difficulty in completing the smallest task he undertakes; this should be pointed out to the patient.

(2) The Figure 1—Dr. Miller classes as an alternative exercise, but it in reality serves a totally different purpose. With difficulty the patient summons his entire concentration, saying the “1” to himself, writing it, and hearing it said. Directly it is finished the mind should rest, the purpose being not to train concentration, but to draw the attention of the case which with the patient leaves the figure, the physician determines the amount of difficulty he has in putting all working thoughts away when he wants to rest.

(3) Tactile exercises are among the most valuable. According to the way the patient feels one thing construe, the physician can determine how great an extent the subjective state is controlling him.

These with all other conscious acts are, I submit, the foundation on which the whole theory of attentive control rests.

(4) Concentration on different parts of the body gives confidence to the patient, as after very little practice a certain pricking sensation comes in the member thought of, and gives him reason to hope that his mind may attain some control over his body.

Putting up numbers and wiping them out is one of the many tricks. Any exercise, however, which shows him whether the patient has the power of retention and not of elimination, or the reverse, it also shows him whether the patient is always looking ahead mentally, or looking back, whether he is inclined to hasten away from what he does not want to think of, or to cover it up with other things; whether things are clear to him, or always rather vague; whether he can keep several things in his mind together, or whether each succeeding thought tends only to obstruct the previous one. Whether he can act decidedly, or whether always with hesitation. It is also possible for the physician to determine by these vibrations whether the patient needs mind training or some other treatment. If the mind is found in a state of very great tension, torpor, or confusion, it is clear that the person needs training, and that may be all that is necessary. As a rule in these cases the mental repression or conflict is near enough to the surface of the conscious to be dealt with by mental training of the mind, and that is sufficient treatment.

If, however, the patient shows certain physical or mental symptoms, and on examination his mind is in a state of comparative clearness, the physician should immediately suspect a much deeper repression, and the analysis would of necessity have to be more
searching. Of course, the patient may suffer from mental confusion and also from an unconscious resistance to treatment. It is usually possible to give two or three weeks' mental training, before beginning an analysis, as it clears the patient's mind of all side issues, gives him a certain amount of confidence in himself, and also gets him into sympathy with the difficulty which saves much time in the ensuing treatment.

11. Having given a few specimens of Vivottz exercises I will now deal with his system of re-education.

It must be borne in mind that Vivottz places absolute reliance on the value to the patient of the exercises he gives him. He finds the patient lacking in mind control in some way, sometimes to a very grave extent, and he argues that it is not except to his total advantage and to the patient's advantage to let him know that he has at his disposal the power to control his mind, and he teaches the patient this from the very beginning of the training. It will be argued that the power of concentration, consciousness, and relaxation is something which has this end in view, but where I think Vivottz's system differs from that of others is that he goes into far greater detail; by means of the exercises he is able to gauge the amount of control the patient has, and to tell him what he must do to make a task he knows he has the power to perform. A great many failures seem to be accounted for by the fact that the physician asks too much, a desperate effort is made and mutilate is the result: or the effort is made with so much tension that a reaction follows, and the patient is in despair. Under Vivottz's system, a very gradual course is followed and the patient gains confidence. By the mechanical exercises he establishes a base line on which he can take his stand. This principle involves a mental training every good physiotherapist has in this end in view, but where I think Vivottz's system differs from that of others is that he goes into far greater detail; by means of the exercises he is able to gauge the amount of control the patient has, and to tell him what he must do to make a task he knows he has the power to perform. A great many failures seem to be accounted for by the fact that the physician asks too much, a desperate effort is made and mutilate is the result: or the effort is made with so much tension that a reaction follows, and the patient is in despair. Under Vivottz's system, a very gradual course is followed and the patient gains confidence. By the mechanical exercises he establishes a base line on which he can take his stand.

The end towards which Vivottz aims is the absolute reliance of the patient on himself; and this principle will be attained at the very beginning of the training. It must be borne in mind that the patient is the author and director of the treatment, and is careful to teach the patient how to be conscious and to relax in great detail. To one patient straight lines are a source of joy, to another anathema, and of course any source of irritation must be immediately removed. A particular exercise so altered in character that though it performs the same service the patient does not recognise it.

The end towards which Vivottz aims is the absolute reliance of the patient on himself; and this principle will be attained at the very beginning of the training. A particular exercise so altered in character that though it performs the same service the patient does not recognise it.
grasp of the principles at bottom of the Vittot education, everything becomes an experience, a real exercise of mental power. He realises that he has a control in himself which he can daily increase, a power of concentration and detachment at will. That, he can go on and on with his powers, in increasing them, experimenting, should be impressed on every intelligent patient; he must not be led to think he is to be turned out at the end of two months' training the 'finished article.'

Another reason why I believe the Vittot system to be underestimated is because few medical men understand to what extent their patients lack concentration. Because they conduct an argument with their physician with some ability he is blinded to the fact that very often they cannot attend a public lecture, and also for this reason his patient. But for those cases in which it is necessary at a certain crisis to use it, I would add a few words which may help the physician. The moment he realises that a 'crisis is imminent, and that some personal help is required of him, he should clear his mind of all and perfectly voluntarily and calmly give out all his power. If he does it with any unwillingness or with excitement he will pay for it in an abnormal fatigue. After seeing a case of this sort he should allow himself a moment or two if possible, to recover the power, so as to be sure that he does not carry over any unnecessary excitement to a case that would be better without it.

EXCERPTS FROM THE REPORT OF THE SELECT COMMITTEE ON PATENT MEDICINES.

The following excerpts from the Report present its findings and recommendations, which are of the highest importance in the public health:

After careful consideration of the evidence laid before them your Committee find:—

(1) That there is a large and increasing sale in this country of patent and proprietary remedies and appliances of Compound medicated wines.

(2) That these remedies are of a widely differing character, comprising (a) genuine scientific preparations; (b) objectionable remedies for simple ailments; and, (c) misleading statements making grossly exaggerated claims of efficacy; causing injury by leading sick persons to delay in securing medical treatment; containing in disguise large proportions of alcohol; sold for improper purposes; professing to cure diseases incurable by medicament; or essentially and deliberately fraudulent.

(3) That this last mentioned class (c) of remedies contains none which are developed from therapeutic or medicinal knowledge, but that they are put upon the market by ignorant persons, and in many cases by cunning swindlers, who exploit for their own profit the apparently invincible credulity of the public.

(4) That this constitutes a grave and widespread public evil.

(5) That in British Dominions and foreign countries severe legal restrictions exist, and that there is a need still further to strengthen the law against these articles.

(6) That no Department of State and no public officer is charged with the duty of controlling the sale and advertising of proprietary remedies in this country; that the Home Office and the Local Government Board are virtually powerless in this respect; that the Privy Council Office, though supposed to be specially concerned with the sale of drugs, has no initiative in the matter, and, in fact, its fulfils no useful function in this connection.

(7) That the existing law is chaotic and has proved inoperative, and that successful prosecution for fraud in the advertisement and sale of Secret remedies is fraught with the greatest difficulty, though the Public Prosecutor might, perhaps not sufficiently tested the powers of the existing law in respect to such cases.

(8) That consequently the traffic in secret remedies, except as regards scheduled poisons and the grosser forms of immediate proprietary, is practically uncontrolled in this country.

(9) That this is an intolerable state of things, and that new legislation to deal with it, rather than merely the amendment of existing laws, is urgently needed in the public interest.

(10) That a grave injury is caused to the public by the existing large sale of medicated wines.

(11) And that while, for reasons already given, it is not desirable to require the exhibition of formula of every secret remedy, nevertheless it is intolerable that under the protection of the law enormous quantities of alleged remedies should be sold the composition of which is unknown to any person except the manufacturer; and, therefore, the formula of all secret remedies should be required to be communicated to a competent officer appointed under the authority of a Minister of State, but that such formula should not be divulged to any other person except as hereinafter recommended.

RECOMMENDATIONS.

56. Your Committee therefore recommend:—

(1) That the administration of the law governing the advertisement and sale of patent, secret and proprietary medicines be co-ordinated and combined under the authority of one Department of State.

(2) That this administration be part of the functions of the Ministry of Public Health, when such Department is created, and that in the meanwhile it be undertaken by the Local Government Board.

(3) That a competent officer be appointed to this Department, with the duty of advising the Minister at the head of the Department concerned regarding the enforcement of the law in respect of these remedies.

(4) That there be established at the Department concerned a register of manufacturers, proprietors and importers of patent, secret and proprietary remedies, and that every such person be required to apply for a certificate of registration and to furnish (a) the principal address of the person trading as such, (b) a statement of the kinds of remedies carried on in this country, and (c) a list of the medicines or medicines proposed to be made or imported.

(5) That an exact and complete statement of the ingredients and the proportions of the same of every patent, secret and proprietary remedy of the contents other than wine, and the alcoholic strength of every medicated wine, and a full statement of the therapeutic claims, made or to be made, and a specimen of every claim, and of the cure of ailments other than recognised surgical appliances, be furnished to this Department, such information not to be disclosed except as hereinafter recommended, the Department to construe such statement, at their discretion, by analyses made confidentially by the Government Chemist.

(6) That a special Court or Commission be constituted with power to permit to be set in a proper case, if it appears to them that there is an intention of non-compliance with the law, the sale and advertisement of any patent, secret or proprietary remedy, or appliance, and that the Commission appointed for the purpose be a judicial authority such as a Metropolitan Police Magistrate sitting with two assessors, one appointed by the Department, and the other by some such body as the London Chamber of Commerce.

(7) That the President of the Local Government (or of Minister of Health) have power to sub-
CORRESPONDENCE.

The Medical Press.

315

stitute the necessary proceedings to enforce com-
pliance with the law, the sale and advertisement
of any patent, secret or proprietary remedy, or
appliance.

(5) That a registration number be assigned to
every remedy permitted to be sold, and that every 
bottle or package of it be required to bear the
imprint "R.N. . . ." (with the number), and that no
other words referring to the registration be
permitted to be printed on the bottle or pack-

(6) That in the case of a remedy the sale of
which is prohibited, the proprietor or manufac-
turer be entitled to appeal to the High Court
against the prohibition.

(11) That the Department be empowered to
require the name and proportion of any poisons
or potent drug forming an ingredient of any
remedy to be exhibited upon the label.

(12) That inspectors be placed at the disposal
of the Department to examine advertisements
and observe the sale of proprietary remedies and
appliances.

(13) That an annual fee be payable in respect
of every registration number issued.

57. Your Committee make the following recom-
mendations regarding the amendment of the existing
laws:

(1) That the Stamp Acts be consolidated and
amended to remove the numerous existing
anomaly[s], or otherwise enable exceptions in
this connection, pure drugs vended entire under a
fancy name should no longer be exempt from
duty; the distinction between the name of an
ailment, and the name of an organ to which it is
due should be maintained; and the exemption of
medicines generating carbonic acid gas should
be omitted (see par. 10). Further, any reference
in advertising matter to the Government stamp
should be prohibited, and no name of a proprietor
or firm be printed upon the stamp.

(2) That the Indecent Advertisements Act be
amended on the lines of Lord Bray's Bill.

58. Your Committee further recommend the follow-
ing further enactments:

(1) That every medicated wine, and every
proprietary remedy containing more alcohol than
that required for pharmacological purposes, be
required to state upon the label the proportion of
alcohol contained in it.

(2) That the advertisement and sale (except
the sale by a doctor's order) of medicines purporting
to cure the following diseases be prohibited—
Cancer Diabetes Locomotor ataxy Consumption Paralysis Bright's disease Epilepsy
Locomotor ataxia Rupture (without opera-

(3) That all advertisements of remedies for
diseases arising from sexual intercourse or refer-
ing to sexual weakness be prohibited.

(4) That all advertisements likely to suggest that
a medicine is an abortifacient be prohibited.

(5) That it be a breach of the law to change
the composition of a remedy without informing
the Department of the proposed change, or that
fancy names for recognised drugs be subject to
regulation.

(6) That the period of validity of a name used
as a trade mark for a drug be limited, as in the
case of patents and copyrights.

(7) That it be a breach of the law to give a
false trade description of any remedy, and that
the following be a definition of a false trade
description—"A statement, design or
regarding any article or preparation, or the
ingredients of medicines contained therein, or
the curative or therapeutic effect thereof, which is
false or misleading in any particular." And that
the onus of proof that he had reasonable ground for
believing it to be a breach of the law to give a
false trade description be placed upon the manu-
ufacturer or proprietor of such remedy.

(8) That it be a breach of the law—

(a) To enclose with one remedy printed
matter recommending another remedy.

(b) To invite sufferers from any ailment to
correspond with the vendor of a remedy.

(c) To make use of the name of a fictitious
person in connection with a remedy. (But it
should be permitted to him the power of applying
permission to permit the exemption of an old-
established remedy from this provision.)

(d) To make use of fictitious testimonials.

(e) To publish a recommendation of a
secret remedy by a medical practitioner unless
his or her full name, qualifications and
address be given.

(f) To promise to return money paid if a
cure is not effected.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Red Cross Hospital at Haddington.

The first Red Cross hospital, already established from
military hospitals, has been established at Haddington. Troops were hurriedly sent to
this district since the outbreak of the war, and a number of
the men were overcome by the effects of
their forced march. There were arrangements
for the treatment of such cases, the Medical Officer, through the Territorial
Association, on arrival, called upon the Voluntary Aid
Detachment at Haddington of the Red Cross Society to
supply a temporary hospital there. The work was
expeditiously and efficiently done by the Detachment.

The military authorities have felt the need of a
continuation of the institution, and have requested the
Scottish Branch of the British Red Cross Society to
recognise it as an auxiliary hospital where cases of ill-
ess of a temporary nature might be treated. The Red Cross authorities have visited the hospital
and found everything most satisfactory. Members of Voluntary Aid Detachments have been sent
by the military authorities to assist at the military hospital
at Maryhill, Glasgow, and at the hospital at
Haddington.

Inoculation of Troops against Typhoid Fever.

Dr. J. J. Graham Brown, the President of the Royal
College of Physicians of Edinburgh, and Dr.
F. M. Caird, the President of the Royal College of
Surgeons of Edinburgh, have issued a communication
to the Press on the advisability of inoculating our
troops against typhoid fever before they go abroad. The high necessity of this procedure, they
point out, does not appear to be sufficiently recog-
nised. Yet our experience in the South African War
showed that, were typhoid fever to break out among
such masses of men, it would destroy many more lives
